The second step is nearly always faster than the first, making the first rate determining, and the reaction is second order. If formation of the attacking species is slower still, the aromatic compound does not take part in the rate expression at all. If X^+ is lost, there is no net reaction, but if H^+ is lost, an aromatic substitution has taken place and a base (generally the counterion of the electrophilic species although solvents can also serve this purpose) is necessary to help remove it.

If the attacking species is not an ion, but a dipole, the product must have a negative charge unless part of the dipole, with its pair of electrons, is broken off somewhere in the process, as in the conversion of **4** to **5**. Note that when the aromatic ring attacks X, Z may be lost directly to give **5**.

The electrophilic entities and how they are formed are discussed for each reaction in the reactions section of this chapter.

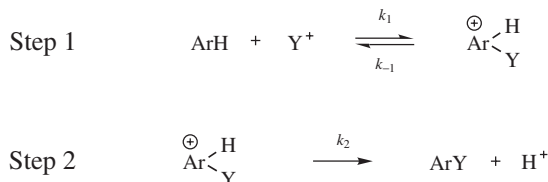

The evidence for the arenium ion mechanism is mainly of two kinds:

- 1. Isotope Effects.** If the hydrogen ion departs before the arrival of the electrophile (S_E1 mechanism) or if the arrival and departure are simultaneous, there should be a substantial isotope effect (i.e., deuterated substrates should undergo substitution more slowly than non-deuterated compounds) because, in each case, the C–H bond is broken in the rate-determining step. However, in the arenium ion mechanism, the C–H bond is not broken in the rate-determining step, so no isotope effect should be found. Many such studies have been carried out and, in most cases, especially in the case of nitrations, there is no isotope effect.⁶ This result is incompatible with either the S_E1 or the simultaneous mechanism.

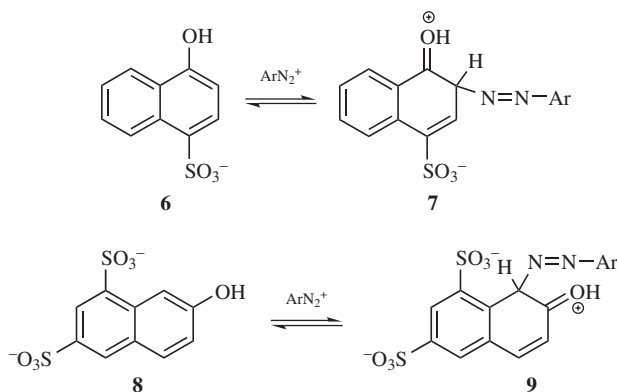

However, in many instances, isotope effects have been found. Since the values are generally much lower than expected for either the S_E1 or the simultaneous mechanisms (e.g., 1–3 for k_H/k_D instead of 6–7), we must look elsewhere for

⁶The pioneering studies were by Melander, L. *Ark. Kemi* **1950**, *2*, 213; Berglund-Larsson, U.; Melander, L. *Ark. Kemi* **1953**, *6*, 219. See also, Zollinger, H. *Adv. Phys. Org. Chem.* **1964**, *2*, 163.

the explanation. For the case where hydrogen is the leaving group, the arenium ion mechanism can be summarized:

The small isotope effects found most likely arise from the reversibility of step 1 by a *partitioning effect*.⁷ The rate at which ArHY^+ reverts to ArH should be essentially the same as that at which ArDY^+ (or ArTY^+) reverts to ArD (or ArT), since the Ar-H bond is not cleaving. However, ArHY^+ should go to ArY faster than either ArDY^+ or ArTY^+ , since the Ar-H bond is broken in this step. If $k_2 \gg k_{-1}$, this does not matter; since a large majority of the intermediates go to product, the rate is determined only by the slow step ($k_1[\text{ArH}][\text{Y}^+]$) and no isotope effect is predicted. However, if $k_2 \leq k_{-1}$, reversion to starting materials is important. If k_2 for ArDY^+ (or ArTY^+) is $< k_2$ for ArHY^+ , but k_{-1} is the same, then a larger proportion of ArDY^+ reverts to starting compounds. That is, k_2/k_{-1} (the *partition factor*) for ArDY^+ is less than that for ArHY^+ . Consequently, the reaction is slower for ArD than for ArH and an isotope effect is observed.

One circumstance that could affect the k_2/k_{-1} ratio is steric hindrance. Thus, diazonium coupling of **6** gave no isotope effect, while coupling of **8** gave a $k_{\text{H}}/k_{\text{D}}$ ratio of 6.55.⁸ For steric reasons, it is much more difficult for **9** to lose a proton (it is harder for a base to approach) than it is for **7**, so k_2 is greater for the latter. Since no base is necessary to remove ArN_2^+ , k_{-1} does not depend on steric factors⁹ and is about the same for each. Thus the partition factor k_2/k_{-1}

⁷For a discussion, see Hammett, L.P. *Physical Organic Chemistry*, 2nd ed., McGraw-Hill, NY, 1970, pp. 172–182.

⁹Snyckers, F.; Zollinger, H. *Helv. Chim. Acta* 1970, 53, 1294.

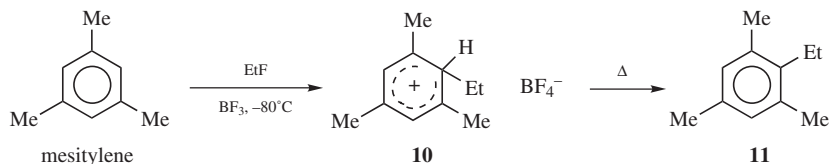

is sufficiently different for **7** and **9** that **8** exhibits a large isotope effect and **6** exhibits none.¹⁰ Base catalysis can also affect the partition factor, since an increase in base concentration increases the rate at which the intermediate goes to product without affecting the rate at which it reverts to starting materials. In some cases, isotope effects can be diminished or eliminated by a sufficiently high concentration of base.

Evidence for the arenium ion mechanism has also been obtained from other kinds of isotope-effect experiments, involving substitutions of the type

where M is Si, Ge, Sn, or Pb, and R is methyl or ethyl. In these reactions, the proton is the electrophile. If the arenium ion mechanism is operating, then the use of D_3O^+ should give rise to an isotope effect, since the D–O bond would be broken in the rate-determining step. Isotope effects of 1.55–3.05 were obtained,¹¹ in accord with the arenium ion mechanism.

2. *Isolation of Arenium Ion Intermediates.* Very strong evidence for the arenium ion mechanism comes from the isolation of arenium ions in a number of instances.¹² For example, **7** was isolated as a solid with a

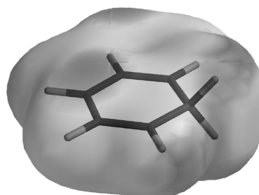

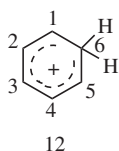

melting point of -15°C from treatment of mesitylene with ethyl fluoride and the catalyst BF_3 at -80°C . When **10** was heated, the normal substitution product **11** was obtained.¹³ Even the simplest such ion, the benzenonium ion (**12**), has been prepared in $\text{HF-SbF}_5\text{-SO}_2\text{ClF-SO}_2\text{F}_2$ at -134°C , where it could be studied

13

spectrally.¹⁴ The ^{13}C NMR spectra of the benzenonium ion¹⁵ and the pentamethylbenzenonium ion¹⁶ give graphic evidence for the charge distribution shown in **1** (see the electron density map for the arenium ion, **13**). According to this, the 1, 3, and 5 carbons, each of which bears a positive charge of $+\frac{1}{3}$ [note that C-1,-3,-5 (numbering from **12**) are lighter, indicating less electron density in **13**, whereas C-2,-4 are darker for higher electron density], should have a greater chemical shift in the NMR than the 2 and 4 carbons, which are uncharged. The spectra bear this out. For example, ^{13}C NMR chemical shifts for **12** are C-3: 178.1; C-1 and C-5: 186.6; C-2 and C-4: 136.9, and C-6: 52.2.¹⁵

In Chapter 3, it was mentioned that positive ions can form addition complexes with π systems. Since the initial step of electrophilic substitution involves attack of a positive ion by an aromatic ring, it has been suggested¹⁷ that such a complex, called a π complex (represented as **14**), is formed first, and then is converted to the arenium ion **15**.¹⁸ Stable solutions of arenium ions or π complexes (e.g., with Br_2 , I_2 ,

picric acid, Ag^+ , or HCl) can be formed.¹⁹ For example, π complexes are formed when aromatic hydrocarbons are treated with HCl alone, but the use of HCl plus a

TABLE 11.1. Relative Stabilities of Arenium Ions and π Complexes and Relative Rates of Chlorination and Nitration^a

Substituents	Relative Arenium Ion Stability ²⁰	Relative π -Complex Stability ²⁰	Rate of Chlorination ²¹	Rate of Nitration ²⁶
None (benzene)	0.09	0.61	0.0005	0.51
Me	0.63	0.92	0.157	0.85
<i>p</i> -Me ₂	1.00	1.00	1.00	1.00
<i>o</i> -Me ₂	1.1	1.13	2.1	0.89
<i>m</i> -Me ₂	26	1.26	200	0.84
1,2,4-Me ₃	63	1.36	340	
1,2,3-Me ₃	69	1.46	400	
1,2,3,4-Me ₄	400	1.63	2,000	
1,2,3,5-Me ₄	16,000	1.67	240,000	
Me ₅	29,900		360,000	

^aIn each case, *p*-xylene = 1.00.

Lewis acid (e.g., AlCl₃) gives arenium ions. The two types of solution have very different properties. For example, a solution of an arenium ion is colored and conducts electricity (showing positive and negative ions are present), while a π complex formed from HCl and benzene is colorless and does not conduct a current. Furthermore, when DCl is used to form a π complex, no deuterium exchange takes place (because there is no covalent bond between the electrophile and the ring), while formation of an arenium ion with DCl and AlCl₃ gives deuterium exchange. The relative stabilities of some methylated arenium ions and π complexes are shown in Table 11.1. The arenium ion stabilities listed were determined by the relative basicity of the substrate toward HF.²⁰ The π complex stabilities are relative equilibrium constants for the reaction²¹ between the aromatic hydrocarbon and HCl. As shown in Table 11.1, the relative stabilities of the two types of species are very different: the π complex stability changes very little with methyl substitution, but the arenium ion stability changes a great deal. It is noted that stable arenium ions have been obtained from large methylene-bridged polycyclic aromatic hydrocarbons.²²

How can we tell if **14** is present on the reaction path? If it is present, there are two possibilities: (1) The formation of **14** is rate determining (the conversion of **14** to **15** is much faster), or (2) the formation of **14** is rapid, and the conversion **14** to **15** is rate determining. One way to ascertain which species is formed in the rate-determining step in a given reaction is to use the stability information given in Table 11.1. We measure the relative rates of reaction of a given electrophile with the series of compounds listed in Table 11.1. If the relative rates resemble the arenium ion stabilities, we conclude that the arenium ion is formed in the slow step; but if they

²²Laali, K.K.; Okazaki, T.; Harvey, R.G. *J. Org. Chem.* **2001**, *66*, 3977.

resemble the stabilities of the π complexes, the latter are formed in the slow step.²³ When such experiments are carried out, it is found in most cases that the relative rates are similar to the arenium ion and not to the π complex stabilities. For example, Table 11.1 lists chlorination rates.²¹ Similar results were obtained in room-temperature bromination with Br_2 in acetic acid²⁴ and in acetylation with $\text{CH}_3\text{CO}^+\text{SbF}_6^-$.²⁵ It is clear that in these cases the π complex either does not form at all, or if it does, its formation is not rate determining (unfortunately, it is very difficult to distinguish between these two possibilities).

On the other hand, in nitration with the powerful electrophile NO_2^+ (in the form of $\text{NO}_2^+\text{BF}_4^-$), the relative rates resembled π complex stabilities much more than arenium ion stabilities (Table 11.1).²⁶ Similar results were obtained for bromination with Br_2 and FeCl_3 in nitromethane. These results were taken to mean²⁷ that in these cases π complex formation is rate determining. However, graphical analysis of the NO_2^+ data showed that a straight line could not be drawn when the nitration rate was plotted against π complex stability,²⁸ which casts doubt on the rate-determining formation of a π complex in this case.²⁹ There is other evidence, from positional selectivities (discussed on p. 682), that *some* intermediate is present before the arenium ion is formed, whose formation can be rate determining with powerful electrophiles. Not much is known about this intermediate, which is given the nondescriptive name *encounter complex* and generally depicted as **16**. The arenium complex mechanism is therefore written as³⁰

For the reason given above and for other reasons, it is unlikely that the encounter complex is a π complex, but just what kind of attraction exists between Y^+ and ArH is not known, other than the presumption that they are together within a solvent cage (see also p. 682). There is evidence (from isomerizations occurring in the alkyl group, as well as other observations) that π complexes are present on the pathway from substrate to arenium ion in the gas-phase protonation of alkylbenzenes.³¹

The S_E1 Mechanism

The S_E1 mechanism (*substitution electrophilic unimolecular*) is rare, being found only in certain cases in which carbon is the leaving atom (see **11-33**, **11-35**) or when a very strong base is present (see **11-1**, **11-10**, and **11-39**).³² It consists of two steps with an intermediate carbanion. The IUPAC designation is $D_E + A_E$.

Reactions **12-41**, **12-45**, and **12-46** also take place by this mechanism when applied to aryl substrates.

ORIENTATION AND REACTIVITY

Orientation and Reactivity in Monosubstituted Benzene Rings³³

When an electrophilic substitution reaction is performed on a monosubstituted benzene, the new group may be directed primarily to the ortho, meta, or para position and the substitution may be slower or faster than with benzene itself. The group already on the ring determines which position the new group will take and whether the reaction will be slower or faster than with benzene. Groups that increase the reaction rate are called *activating* and those that slow it *deactivating*. Some groups are predominantly meta directing; all of these are deactivating. Others are mostly ortho-para directing; some of these are deactivating too, but most are activating. Groups direct *predominantly*, but usually not *exclusively*. For example, nitration of nitrobenzene gave 93% *m*-dinitrobenzene, 6% of the ortho, and 1% of the para isomer.

The orientation and reactivity effects are explained on the basis of resonance and field effects of each group on the stability of the intermediate arenium ion. To understand why we can use this approach, it is necessary to know that in these reactions

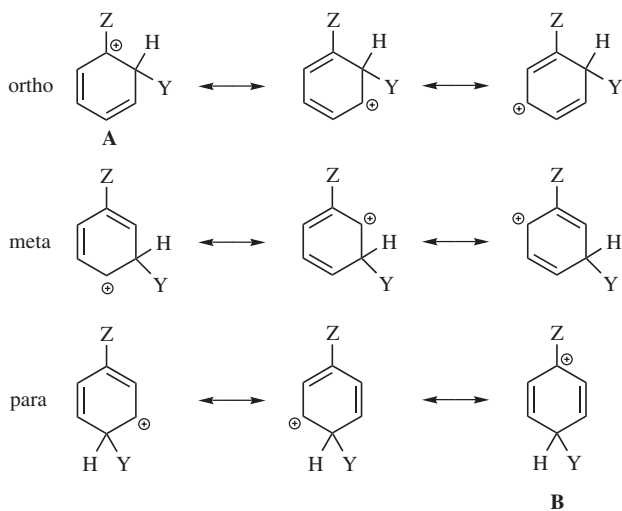

³¹Holman, R.W.; Gross, M.L. *J. Am. Chem. Soc.* **1989**, *111*, 3560.

³²It has also been found with a metal ($SnMe_3$) as electrofuge: Eaborn, C.; Hornfeld, H.L.; Walton, D.R.M. *J. Chem. Soc. B* **1967**, 1036.

³³For a review of orientation and reactivity in benzene and other aromatic rings, see Hoggett, J.G.; Moodie, R.B.; Penton, J.R.; Schofield, K. *Nitration and Aromatic Reactivity*, Cambridge University Press, Cambridge, **1971**, pp. 122–145, 163–220.

the product is usually kinetically and not thermodynamically controlled (see p. 307). Some of the reactions are irreversible and the others are usually stopped well before equilibrium is reached. *Therefore, which of the three possible intermediates is formed is dependent not on the thermodynamic stability of the products, but on the activation energy necessary to form each of the three intermediates.* It is not easy to predict which of the three activation energies is lowest, but we make the assumption that the free-energy profile resembles either Fig. 6.2(a or b). In either case, the transition state is closer in energy to the arenium ion intermediate than to the starting compounds. Invoking the Hammond postulate (p. 308), we can then assume that the geometry of the transition state also resembles that of the intermediate and that anything that increases the stability of the intermediate will also lower the activation energy necessary to attain it. Since the intermediate, once formed, is rapidly converted to products, we can use the relative stabilities of the three intermediates as guides to predict which products will predominantly form. Of course, if reversible reactions are allowed to proceed to equilibrium, we may get product ratios that are quite different. For example, the sulfonation of naphthalene at 80°C, where the reaction does not reach equilibrium, gives mostly α -naphthalenesulfonic acid,³⁴ while at 160°C, where equilibrium is attained, the β isomer predominates³⁵ (the α isomer is thermodynamically less stable because of steric interaction between the SO₃H group and the hydrogen at the 8 position).

The three possible ions from incorporation of Y at the ortho, meta, and para positions are shown, and each arenium ion obviously has a positive charge in the ring.

We can therefore predict that any group Z that has an electron-donating field effect (+I, Z will have a $-$ charge or a δ^- dipole in most cases) should stabilize all three

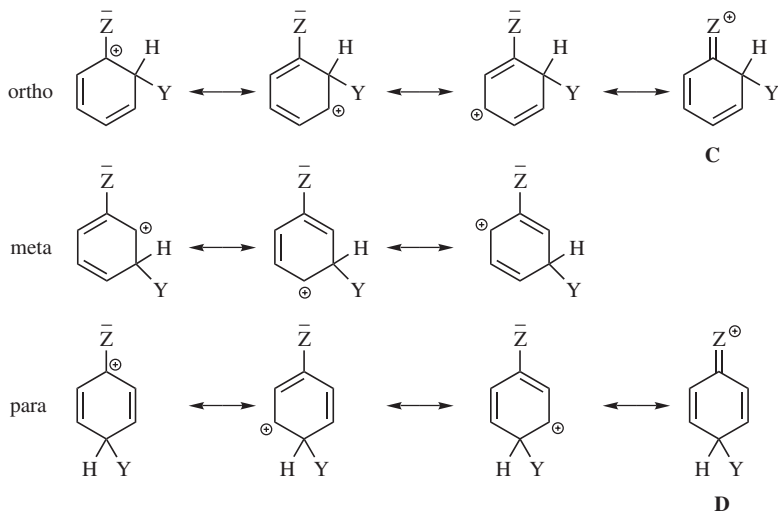

³⁴Fierz, H.E.; Weissenbach, P. *Helv. Chim. Acta* **1920**, 3, 312.

³⁵Witt, O.N. *Berchti* **1915**, 48, 743.

ions (relative to **1**), since electron donation to a positive center is stabilizing. On the other hand, electron-withdrawing groups ($-I$, Z will have a $+$ charge or a $\delta+$ dipole in most cases) will increase the positive charge on the ring (like charges repel), and destabilize the arenium ion. Formation of a stabilized ion should be faster than benzene (which generates **1**), or activating, but formation of a destabilized ion should be slower, or deactivating. Such field effects should taper off with distance and are thus strongest at the carbon connected to the group Z (known as the ipso carbon). Of the three arenium ions, only the ortho and para have any positive charge at this carbon. None of the canonical forms of the meta ion has a positive charge at the ipso carbon. Therefore, $+I$ groups should stabilize all three ions but mostly the ortho and para, so they should be not only activating but ortho-para-directing as well. On the other hand, $-I$ groups, by removing electron density, should destabilize all three ions but mostly the ortho and para, and should be not only deactivating but also meta-directing.

These conclusions are correct as far as they go, but they do not lead to the proper results in all cases. In many cases, there is *resonance interaction* between Z and the ring; this also affects the relative stability, in some cases in the same direction as the field effect, in others differently.

Some substituents have a pair of electrons (usually unshared) that may be contributed *toward* the ring. The three arenium ions would then look like this:

For each ion the same three canonical forms can be drawn as before, but now we can draw an extra form for the ortho and para ions. The stability of these two ions is increased by the extra form not only because it is another canonical form, but because it is more stable than the others and makes a greater contribution to the hybrid. Every atom (except of course hydrogen) in these forms (**C** and **D**) has a complete octet, while all the other forms have one carbon atom with a sextet. No corresponding form can be drawn for the meta isomer. The inclusion of this form in

the hybrid lowers the energy not only because of rule 6 (p. 47), but also because it spreads the positive charge over a larger area—out onto the group Z. Groups with a pair of electrons (e.g., as the halogens) to contribute would be expected, then, in the absence of field effects, not only to direct ortho and para, but also to activate these positions for electrophilic attack.

On the basis of these discussions, we can distinguish three types of groups.

1. Groups that contain an unshared pair of electrons on the atom connected to the ring. In this category are O^- , NR_2 , NHR , NH_2 ,³⁶ OH , OR , $NHCOR$, $OCOR$, SR , and the four halogens.³⁷ The halogens deactivate the aromatic ring to substitution (the rate of reaction is slower than that of benzene), and this effect may arise from the unique energy level of the halogen lone-pair orbital, which is higher than the adjacent π -molecular orbital of benzene (π_1).³⁸ The widely held explanation for this, however, is that the halogens have a $-I$ effect. The SH group would probably belong here too, except that in the case of thiophenols electrophiles usually attack the sulfur rather than the ring, and ring substitution is not feasible with these substrates.³⁹ The resonance explanation predicts that all these groups should be ortho-para directing, and they are, though all except O^- are electron withdrawing by the field effect (p. 20). Therefore, for these groups, resonance is more important than the field effect. This is especially true for NR_2 , NHR , NH_2 , and OH , which are *strongly* activating, as is O^- . The other groups are mildly activating, except for the halogens, which are deactivating. Fluorine is the least deactivating, and fluorobenzenes usually show a reactivity approximating that of benzene itself. The other three halogens deactivate about equally. In order to explain why chlorine, bromine, and iodine deactivate the ring, even though they direct ortho-para, we must assume that the canonical forms **C** and **D** make such great contributions to the respective hybrids that they make the ortho and para arenium ions more stable than the meta, even though the $-I$ effect of the halogen is withdrawing sufficient electron density from the ring to deactivate it. The three halogens make the ortho and para ions more stable than the meta, but less stable than the unsubstituted arenium ion (**I**). For the other groups that contain an unshared pair, the ortho and para ions are more stable than either the meta ion or the unsubstituted ion. For most of

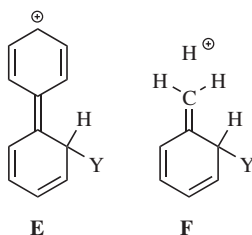

³⁶It must be remembered that in acid solution amines are converted to their conjugate acids, which for the most part are meta-directing (type 2). Therefore in acid (which is the most common medium for electrophilic substitutions) amino groups may direct meta. However, unless the solution is highly acidic, there will be a small amount of free amine present, and since amino groups are activating and the conjugate acids deactivating, ortho-para direction is often found even under acidic conditions.

³⁷For a review of the directing and orienting effects of amino groups, see Chuchani, G., in Patai's. *The Chemistry of the Amino Group*, Wiley, NY, **1968**, pp. 250–265; for ether groups see Kohnstam, G.; Williams, D.L.H., in Patai's. *The Chemistry of the Ether Linkage*, Wiley, NY, **1967**, pp. 132–150.

³⁹Tarbell, D.S.; Herz, A.H. *J. Am. Chem. Soc.* **1953**, *75*, 4657. Ring substitution is possible if the SH group is protected. For a method of doing this, see Walker, D. *J. Org. Chem.* **1966**, *31*, 835.

- the groups in this category, the meta ion is more stable than **1**, so that groups, such as NH_2 and, OH , activate the meta positions too, but not as much as the ortho and para positions (see also the discussion on pp. 677–679).
2. Groups that lack an unshared pair on the atom connected to the ring and that are $-I$. In this category are, in approximate order of decreasing deactivating ability, NR_3^+ , NO_2 , CF_3 ,⁴⁰ CN , SO_3H , CHO , COR , COOH , COOR , CONH_2 , CCl_3 , and NH_3^+ . Also in this category are all other groups with a positive charge on the atom directly connected to the ring⁴¹ (SR_2^+ , PR_3^+ , etc.) and many groups with positive charges on atoms farther away, since often these are still powerful $-I$ groups. The field-effect explanation predicts that these should all be meta directing and deactivating, and (except for NH_3^+) this is the case. The NH_3^+ group is an anomaly, since this group directs para about as much as or a little more than it directs meta.⁴² The NH_2Me^+ , NHMe_2^+ , and NMe_3^+ groups all give more meta than para substitution, the percentage of para product decreasing with the increasing number of methyl groups.⁴³
 3. Groups that lack an unshared pair on the atom connected to the ring and that are ortho–para directing. In this category are alkyl groups, aryl groups, and the COO^- group,⁴⁴ all of which activate the ring. We will discuss them separately. Since aryl groups are $-I$ groups, they might seem to belong to category 2. They are nevertheless ortho–para directing and activating. This can be explained in a similar manner as in category 1, with a pair of electrons from the aromatic sextet playing the part played by the unshared pair, so

that we have forms like **E**. The effect of negatively charged groups like COO^- is easily explained by the field effect (negatively charged groups are of

⁴⁰For the long-range electron-withdrawing effects of this group, see Castagnetti, E.; Schlosser, M. *Chem. Eur. J.* **2002**, *8*, 799.

⁴⁴Spryskov, A.A.; Golubkin, L.N. *J. Gen. Chem. USSR* **1961**, *31*, 833. Since the COO^- group is present only in alkaline solution, where electrophilic substitution is not often done, it is seldom met with.

course electron donating), since there is no resonance interaction between the group and the ring. The effect of alkyl groups can be explained in the same way, but, in addition, we can also draw canonical forms, even though there is no unshared pair. These of course are hyperconjugation forms like **F** (see p. 669). This effect, like the field effect, predicts activation and ortho–para direction, so that it is not possible to say how much each effect contributes to the result. Another way of looking at the effect of alkyl groups (which sums up both field and hyperconjugation effects) is that (for $Z = R$) the ortho and para arenium ions are more stable because each contains a form (**A** and **B**) that is a tertiary carbocation, while all the canonical forms for the meta ion and for **1** are secondary carbocations. In activating ability, alkyl groups usually follow the Baker–Nathan order (p. 96), but not always.⁴⁵

The Ortho/Para Ratio⁴⁶

When an ortho–para-directing group is on a ring, it is usually difficult to predict how much of the product will be the ortho isomer and how much the para isomer. Indeed, these proportions can depend greatly on the reaction conditions. For example, chlorination of toluene gives an ortho/para ratio anywhere from 62:38 to 34:66.⁴⁷ Nevertheless, certain points can be made. On a purely statistical basis there would be 67% ortho and 33% para, since there are two ortho positions and only one para. However, the phenonium ion

12, which arises from protonation of benzene, has the approximate charge distribution shown⁴⁸ (see **13** as well). If we accept this as a model for the arenium ion in aromatic substitution, a para substituent would have a greater stabilizing effect on the adjacent carbon than an ortho substituent. If other effects are absent, this would mean that >33% para and <67% ortho substitution would be found. In hydrogen exchange (reaction **11-1**), where other effects are absent, it has been found for a number of substituents that the average ratio of the logarithms of the partial rate

⁴⁵For examples of situations where the Baker–Nathan order is not followed, see Eaborn, C.; Taylor, R. *J. Chem. Soc.* **1961**, 247; Utley, J.H.P.; Vaughan, T.A. *J. Chem. Soc. B* **1968**, 196; Schubert, W.M.; Gurka, D.F. *J. Am. Chem. Soc.* **1969**, 91, 1443; Himoe, A.; Stock, L.M. *J. Am. Chem. Soc.* **1969**, 91, 1452.

⁴⁶For a discussion, see Pearson, D.E.; Buehler, C.A. *Synthesis* **1971**, 455 see pp 455–464. For a discussion of the influence of reaction conditions on the ortho/para ratio, see Effenberger, F.; Maier, A.J. *J. Am. Chem. Soc.* **2001**, 123, 3429.

⁴⁸Olah, G.A. *Acc. Chem. Res.* **1970**, 4, 240, p. 248.

factors for these positions (see p. 677 for a definition of partial rate factor) was close to 0.865,⁴⁹ which is not far from the value predicted from the ratio of charge densities in **12**. This picture is further supported by the fact that meta-directing groups, which destabilize a positive charge, give ortho/para ratios $>67:33$ ⁵⁰ (of course the total amount of ortho and para substitution with these groups is small, but the *ratios* are generally $>67:33$). Another important factor is the steric effect. If either the group on the attacking ring or the group on the electrophile is large, steric hindrance inhibits formation of the ortho product and increases the amount of the para isomer. An example may be seen in the nitration, under the same conditions, of toluene and *tert*-butylbenzene. The former gave 58% of the ortho compound and 37% of the para, while the more bulky *tert*-butyl group gave 16% of the ortho product and 73% of the para.⁵¹ Some groups are so large that they direct almost entirely para.

When the ortho–para-directing group is one with an unshared pair (this of course applies to most of them), there is another effect that increases the amount of para product at the expense of the ortho. A comparison of the intermediates involved (p. 667) shows that **C** is a canonical form with an ortho-quinoid structure, while **D** has a para-quinoid structure. Since we know that para-quinones are more stable than the ortho isomers, it seems reasonable to assume that **D** is more stable than **C**, and therefore contributes more to the hybrid and increases its stability compared to the ortho intermediate.

It has been shown that it is possible to compel regiospecific para substitution by enclosing the substrate molecules in a cavity from which only the para position projects. Anisole was chlorinated in solutions containing a cyclodextrin, a molecule in which the anisole is almost entirely enclosed (see Fig. 3.4). With a high enough concentration of cyclodextrin, it was possible to achieve a para/ortho ratio of 21.6⁵² (in the absence of the cyclodextrin the ratio was only 1.48). This behavior is a model for the regioselectivity found in the action of enzymes.

IpsO Attack

We have discussed orientation in the case of monosubstituted benzenes entirely in terms of attachment at the ortho, meta, and para positions, but attachment at the

position bearing the substituent (called the *ipso position*⁵³) can also be important. Ipso attack has mostly been studied for nitration.⁵⁴ When attack of NO_2^+ leads to incorporation at the ipso position there are at least five possible fates for the resulting arenium ion (**17**).

Path a. The arenium ion can lose NO_2^+ and revert to the starting compounds. This results in no net reaction and is often undetectable.

Path b. The arenium ion can lose Z^+ , in which case this is simply aromatic substitution with a leaving group other than H (see **11-33–11-41**).

Path c. The electrophilic group (in this case NO_2^+) can undergo a 1,2-migration, followed by loss of the proton. The product in this case is the same as that obtained by direct attachment of NO_2^+ at the ortho position of PhZ . It is not always easy to tell how much of the ortho product in any individual case arises from this pathway,⁵⁵ though there is evidence that it can be a considerable proportion. Because of this possibility, many of the reported conclusions about the relative reactivity of the ortho, meta, and para positions are cast into doubt, since some of the product may have arisen not from direct attachment at the ortho position, but from attachment at the ipso position followed by rearrangement.⁵⁶

Path d. The ipso substituent (Z) can undergo 1,2-migration, which also produces the ortho product (though the rearrangement would become apparent if there

⁵⁶This was first pointed out by Myhre, P.C. *J. Am. Chem. Soc.* **1972**, *94*, 7921.

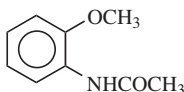

were other substituents present). The evidence is that this pathway is very minor, at least when the electrophile is NO_2^+ .⁵⁷

Path e. Attack of a nucleophile on **17**. In some cases, the products of such an attack (cyclohexadienes) have been isolated⁵⁸ (this is 1,4-addition to the aromatic ring), but further reactions are also possible.

Orientation in Benzene Rings With More Than One Substituent⁵⁹

It is often possible in these cases to predict the correct isomer. In many cases, the groups already on the ring reinforce each other. Thus, 1,3-dimethylbenzene is substituted at the 4 position (ortho to one group and para to the other), but not at the 5 position (meta to both). Likewise, the incoming group in *p*-chlorobenzoic acid goes to the position ortho to the chloro and meta to the carboxyl group.

When the groups oppose each other, predictions may be more difficult. In a case such as where two

groups of about equal directing ability are in competing positions, all four products can be expected, and it is not easy to predict the proportions, except that steric hindrance should probably reduce the yield of substitution ortho to the acetamido group, especially for large electrophiles. Mixtures of about equal proportions are frequent in such cases. Nevertheless, even when groups on a ring oppose each other, there are some regularities.

1. If a strong activating group competes with a weaker one or with a deactivating group, the former controls. Thus *o*-cresol gives substitution mainly ortho and para to the *hydroxyl* group and not to the methyl. For this purpose we can arrange the groups in the following order: $\text{NH}_2, \text{OH}, \text{NR}_2, \text{O}^- > \text{OR}, \text{OCOR}, \text{NHCOR} > \text{R}, \text{Ar} > \text{halogen} > \text{meta-directing groups}$.
2. All other things being equal, a third group is least likely to enter between two groups in the meta relationship. This is the result of steric hindrance and increases in importance with the size of the groups on the ring and with the size of the attacking species.⁶⁰

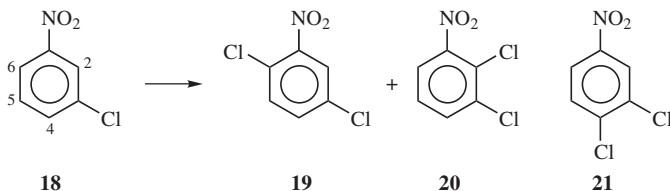

⁵⁷For examples of such migration, where $\text{Z} = \text{Me}$, see Hartshorn, M.P.; Readman, J.M.; Robinson, W.T.; Sies, C.W.; Wright, G.J. *Aust. J. Chem.* **1988**, *41*, 373.

⁵⁸For examples, see Banwell, T.; Morse, C.S.; Myhre, P.C.; Vollmar, A. *J. Am. Chem. Soc.* **1977**, *99*, 3042; Fischer, A.; Greig, C.C. *Can. J. Chem.* **1978**, *56*, 1063.

⁵⁹For a quantitative discussion, see pp. 677–678.

⁶⁰In some cases, attack at an electrophile preferentially leads to attachment at the position between two groups in the meta relationship. For a list of some of these cases and a theory to explain them, see Kruse, L.I.; Cha, J.K. *J. Chem. Soc., Chem. Commun.* **1982**, 1333.

3. When a meta-directing group is meta to an ortho-para-directing group, the incoming group primarily goes ortho to the meta-directing group rather than para. For example, chlorination of **18** gives mostly **19**.

The importance of this effect is underscored by the fact that **20**, which is in violation of the preceding rule, is formed in smaller amounts, but **21** is not formed at all. This is called the *ortho effect*,⁶¹ and many such examples are known.⁶² Another is the nitration of *p*-bromotoluene, which gives 2,3-dinitro-4-bromotoluene. In this case, once the first nitro group came in, the second was directed ortho to it rather than para, even though this means that the group has to come in between two groups in the meta position. There is no good explanation yet for the ortho effect, though possibly there is intramolecular assistance from the meta-directing group.

It is interesting that chlorination of **18** illustrates all three rules. Of the four positions open to the electrophile, the 5 position violates rule 1, the 2 position rule 2, and the 4 position rule 3. The principal attachment is therefore at position 6.

Orientation in Other Ring Systems⁶³

In fused ring systems, the positions are not equivalent and there is usually a preferred orientation, even in the unsubstituted hydrocarbon. The preferred positions may often be predicted as for benzene rings. Thus it is possible to draw more canonical forms for the arenium ion when attack by naphthalene leads to attachment of the electrophile at the α position than when attack by naphthalene leads to attachment of the electrophile at the β position. Therefore, the α position is the preferred site of attachment,⁶⁴ though, as previously mentioned (p. 666), the isomer formed by substitution at the β -position is thermodynamically more stable and is the product if the reaction is reversible and equilibrium is reached. Because of the more extensive delocalization of charges in the corresponding arenium ions, naphthalene is more reactive than benzene and substitution is faster at both positions. Similarly,

⁶¹This is not the same as the ortho effect mentioned on p. 412.

⁶²See Hammond, G.S.; Hawthorne, M.F., in Newman, M.S. *Steric Effects in Organic Chemistry*, Wiley, NY, **1956**, pp. 164–200, 178–182.

For a review of aromatic substitution on ferrocenes, see Bublit, D.E.; Rinehart Jr., K.L. *Org. React.* **1969**, *17*, 1.

⁶⁴For a discussion on the preferred site of attachment for many ring systems, see de la Mare, P.B.D.; Ridd, J.H. *Aromatic Substitution Nitration and Halogenation*, Academic Press, NY, **1959**, pp. 169–209.

anthracene, phenanthrene, and other fused polycyclic aromatic hydrocarbons are also substituted faster than benzene.

Heterocyclic compounds, too, have nonequivalent positions, and the principles are similar,⁶⁵ in terms of mechanism, and rate data is available.⁶⁶ Furan, thiophene, and pyrrole are chiefly substituted at the 2 position, and all are substituted faster than benzene.⁶⁷ Pyrrole is particularly reactive, with a reactivity approximating that of aniline or the phenoxide ion. For pyridine,⁶⁸ it is not the free base that must attack the electrophile, but the conjugate acid (the pyridinium ion),⁶⁹ making the reactivity much less than that of benzene, being similar to that of nitrobenzene. The 3 position is most reactive in electrophilic substitution reactions of pyridine. However, groups can be introduced into the 4 position of a pyridine ring indirectly, by performing the reaction on the corresponding pyridine *N*-oxide.⁷⁰ Note that calculations show that the 2-pyridyl and 2-pyrimidyl cations are best represented as *ortho*-hetaryonium ions, being more stable than their positional, nonconjugated isomers by as much as 18–28 kcal mol⁻¹ (75–11) kJ mol⁻¹.⁷¹

When fused ring systems contain substituents, successful predictions can often be made by using a combination of the above principles. Thus, ring A of 2-methylnaphthalene (**22**) is activated by the methyl

group; ring B is not (though the presence of a substituent in a fused ring system affects all the rings,⁷² the effect is generally greatest on the ring to which it is attached). We therefore expect substitution in ring A. The methyl group activates positions 1 and 3, which are *ortho* to itself, but not position 4, which is *meta* to it.

⁷⁰Jaffé, H.H. *J. Am. Chem. Soc.* **1954**, *76*, 3527.

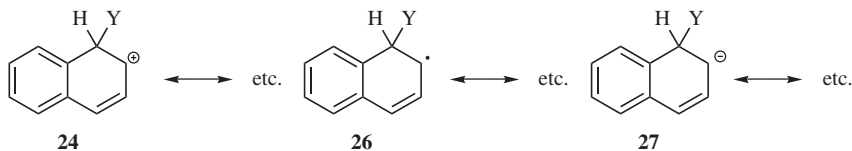

⁷¹Gozzo, F.C.; Eberlin, M.N. *J. Org. Chem.* **1999**, *64*, 2188.

⁷²See, for example, Ansell, H.V.; Sheppard, P.J.; Simpson, C.F.; Stroud, M.A.; Taylor, R. *J. Chem. Soc. Perkin Trans. 2* **1979**, 381.

However, substitution at the 3 position gives rise to an arenium ion for which it is impossible to write a low-energy canonical form in which ring B has a complete sextet. All we can write are forms like **23**, in which the sextet is no longer intact. In contrast, substitution at the 1 position gives rise to a more stable arenium ion, for which two canonical forms (one of them is **24**) can be written in which ring B is benzenoid. We thus predict predominant substitution at C-1, and that is what is generally found.⁷³ However, in some cases predictions are much harder to make. For example, chlorination or nitration of **25** gives mainly the 4 derivative, but bromination yields chiefly the 6 compound.⁷⁴

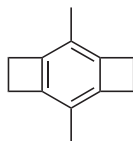

For fused heterocyclic systems too, we can often make predictions based on the above principles, though many exceptions are known. Thus, indole is chiefly substituted in the pyrrole ring (at position 3) and reacts faster than benzene, while quinoline generally reacts in the benzene ring, at the 5 and 8 positions, and slower than benzene, though faster than pyridine.

In alternant hydrocarbons (p. 69), the reactivity at a given position is similar for electrophilic, nucleophilic, and free-radical substitution, because the same kind of resonance can be shown in all three types of intermediate (cf. **24**, **26**, and **27**). Attachment of the electrophile at the position that will best delocalize a positive charge will also best delocalize a negative charge or an unpaired electron. Most results are in accord with these predictions. For example, naphthalene is attacked primarily at the 1 position by NO_2^+ , NH_2^- , and Ph^\bullet , and always more readily than benzene.

⁷³For example, see Alcorn, P.G.E.; Wells, P.R. *Aust. J. Chem.* **1965**, *18*, 1377, 1391; Eaborn, C.; Golborn, P.; Spillett, R.E.; Taylor, R. *J. Chem. Soc. B* **1968**, 1112; Kim, J.B.; Chen, C.; Krieger, J.K.; Judd, K.R.; Simpson, C.C.; Berliner, E. *J. Am. Chem. Soc.* **1970**, *92*, 910. ⁷⁴Bell, F. *J. Chem. Soc.* **1959**, 519.

28

When strain due to a ring fused on an aromatic ring deforms that ring out of planarity, the molecule is more reactive to electrophilic aromatic substitution.⁷⁵ This has been explained by the presence of a shortened bond for the sp^2 hybridized carbon, increasing the strain at that position, and this is known as the *Mills–Nixon effect*.⁷⁶ There is EPR evidence (see p. 267) for 3,6-dimethyl-1,2,4,5-tetrahydrobenzo-bis(cyclobutene) (**28**) that supports the Mills–Nixon effect,⁷⁷ and a theoretical study supports this.⁷⁸ However, *ab initio* studies of triannulated benzene rings shows *no evidence* for the Mills–Nixon effect, and a new motif for bond-alternating benzenes was proposed.⁷⁹ Indeed, it is argued that the Mills–Nixon effect is not real.⁸⁰

Quantitative Treatments of Reactivity in the Substrate

Quantitative rate studies of aromatic substitutions are complicated by the fact that there are usually several hydrogens that can leave, so that measurements of overall rate ratios do not give a complete picture as they do in nucleophilic substitutions, where it is easy to compare substrates that have only one possible leaving group in a molecule. What is needed is not, say, the overall rate ratio for acetylation of toluene versus that for benzene, but the *rate ratio at each position*. These can be calculated from the overall rates and a careful determination of the proportion of isomers formed, provided that the products are kinetically controlled, as is usually the case. We may thus define the *partial rate factor* for a given group and a given reaction as the rate of substitution at a single position relative to a single position in benzene. For example, for acetylation

of toluene the partial rate factors are: for the ortho position $o_f^{\text{Me}} = 4.5$, for the meta $m_f^{\text{Me}} = 4.8$, and for the para $p_f^{\text{Me}} = 749$.⁸¹ This means that toluene is acetylated at

⁷⁵Taylor, R. *Electrophilic Aromatic Substitution*, Wiley, Chichester, **1990**, pp. 53.

⁷⁹Baldrige, K.K.; Siegel, J.J. *J. Am. Chem. Soc.* **1992**, *114*, 9583.

⁸⁰Siegel, J.S. *Angew. Chem. Int. Ed.* **1994**, *33*, 1721.

⁸¹Brown, H.C.; Marino, G.; Stock, L.M. *J. Am. Chem. Soc.* **1959**, *81*, 3310.

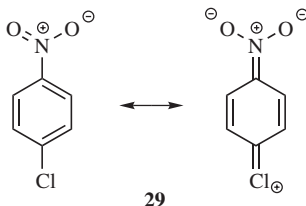

the ortho position 4.5 times as fast as a single position in benzene, or 0.75 times as fast as the overall rate of acetylation of benzene. A partial rate factor >1 for a given position indicates that the group in question activates that position for the given reaction. Partial rate factors differ from one reaction to another and are even different, though less so, for the same reaction under different conditions.

Once we know the partial rate factors, we can predict the proportions of isomers to be obtained when two or more groups are present on a ring, *if we make the assumption that the effect of substituents is independent*. For example, if the two methyl groups in *m*-xylene have the same effect as the methyl group in toluene, we can calculate the theoretical partial rate factors at each position by multiplying those from toluene, so they should be as indicated:

TABLE 11.2. Calculated and Experimental Isomer Distributions in the Acetylation of *m*-Xylene⁸¹

Position	Isomer Distribution, %	
	Calculated	Observed
2	0.30	0
4	9.36	97.5
5	0.34	2.5

From this, it is possible to calculate the overall theoretical rate ratio for acetylation of *m*-xylene relative to benzene, since this is one-sixth the sum of the partial rate factors (in this case 1130), and the isomer distribution if the reaction is kinetically controlled. The overall rate ratio actually is 347⁸² and the calculated and observed isomer distributions are listed in Table 11.2.⁷⁶ In this case, and in many others, agreement is fairly good, but many cases are known where the effects are not additive (as on p. 671).⁸³ For example, this treatment predicts that for 1,2,3-trimethylbenzene

⁸²Marino, G.; Brown, H.C. *J. Am. Chem. Soc.* **1959**, *81*, 5929.

⁸³For some examples where additivity fails, see Fischer, A.; Vaughan, J.; Wright, G.J. *J. Chem. Soc. B* **1967**, 368; Coombes, R.G.; Crout, D.H.G.; Hoggett, J.G.; Moodie, R.B.; Schofield, K. *J. Chem. Soc. B* **1970**, 347; Richards, K.E.; Wilkinson, A.L.; Wright, G.J. *Aust. J. Chem.* **1972**, *25*, 2369; Cook, R.S.; Phillips, R.; Ridd, J.H. *J. Chem. Soc. Perkin Trans. 2* **1974**, 1166. For a theoretical treatment of why additivity fails, see Godfrey, M. *J. Chem. Soc. B* **1971**, 1545.

there should be 35% 5 substitution and 65% 4 substitution, but acetylation gave 79% 5 substitution and 21% of the 4 isomer. The treatment is thrown off by steric effects, such as those mentioned earlier (p. 673), by-products arising from ipso attack (p. 671) and by resonance interaction *between* groups (e.g., **29**), which must make the results deviate from simple additivity of the effects of the groups.

Another approach that avoids the problem created by having competing leaving groups present in the same substrate is the use of substrates that contain only one leaving group. This is most easily accomplished by the use of a leaving group other than hydrogen. By this means overall rate ratios can be measured for specific positions.⁸⁴ Results obtained in this way⁸⁵ give a reactivity order quite consistent with that for hydrogen as leaving group.

A quantitative scale of reactivity for aromatic substrates (fused, heterocyclic, and substituted rings) has been devised, based on the hard-soft acid-base concept (p. 375).⁸⁶ From molecular-orbital theory, a quantity called *activation hardness* can be calculated for each position of an aromatic ring. The smaller the activation hardness, the faster the attachment at that position; hence the treatment predicts the most likely orientations for incoming groups.

A Quantitative Treatment of Reactivity of the Electrophile: The Selectivity Relationship

Not all electrophiles are equally powerful. The nitronium ion attacks not only benzene but also aromatic rings that contain a strongly deactivating group. On the other hand, diazonium ions couple only with rings containing a powerful activating group. Attempts have been made to correlate the influence of substituents with the power of the attacking group. The most obvious way to do this is with the Hammett equation (p. 392):

$$\log \frac{k}{k_0} = \rho \sigma$$

For aromatic substitution,⁸⁷ k_0 is divided by 6 and, for meta substitution, k is divided by 2, so that comparisons are made for only one position (consequently, k/k_0 for, say, the methyl group at a para position is identical to the partial rate factor p_f^{Me}). It was soon found that, while this approach worked fairly well for electron-withdrawing groups, it failed for those that are electron donating. However, if the equation is modified by the insertion of the Brown σ^+ values instead of the Hammett σ values (because a positive charge develops during the transition state), more satisfactory correlations can be made, even for electron-donating groups (see Table 9.4

TABLE 11.3. Relative Rates and Product Distributions in Some Electrophilic Substitutions on Toluene and Benzene⁸⁹

Reaction	Relative Rate	Product Distribution, %	
	$k_{\text{toluene}}/k_{\text{benzene}}$	<i>m</i>	<i>p</i>
Bromination	605	0.3	66.8
Chlorination	350	0.5	39.7
Benzoylation	110	1.5	89.3
Nitration	23	2.8	33.9
Mercuration	7.9	9.5	69.5
Isopropylation	1.8	25.9	46.2

for a list of σ^+ values).⁸⁸ Groups with a negative value of σ_p^+ or σ_m^+ are activating for that position; groups with a positive value are deactivating. The ρ values correspond to the susceptibility of the reaction to stabilization or destabilization by the Z group and to the reactivity of the electrophile. The ρ values vary not only with the electrophile, but also with conditions. A large negative value of ρ means an electrophile of relatively low reactivity. Of course, this approach is completely useless for ortho substitution, since the Hammett equation does not apply there.

A modification of the Hammett approach, suggested by Brown, called the *selectivity relationship*,⁸⁹ is based on the principle that reactivity of a species varies inversely with selectivity. Table 11.3 shows how electrophiles can be arranged in order of selectivity as measured by two indexes: (1) their selectivity in attacking toluene rather than benzene, and (2) their selectivity between the meta and para positions in toluene.⁹⁰ As the table shows, an electrophile more selective in one respect is also more selective in the other. In many cases, electrophiles known to be more stable (hence less reactive) than others show a higher selectivity, as would be expected. For example, the *tert*-butyl cation is more stable and more selective than the isopropyl (p. 236), and Br_2 is more selective than Br^+ . However, deviations from the relationship are known.⁹¹ Selectivity depends not only on the nature of the electrophile but also on the temperature. As expected, it normally decreases with increasing temperature.

Brown assumed that a good measurement of selectivity was the ratio of the para and meta partial rate factors in toluene. He defined the selectivity S_f of a reaction as

$$S_f = \log \frac{p_f^{\text{Me}}}{m_f^{\text{Me}}}$$

⁸⁸For a discussion of the limitations of the Hammett equation approach, see Koptuyg, V.A.; Salakhutdinov, N.F.; Detsina, A.N. *J. Org. Chem. USSR* **1984**, *20*, 1039.

⁸⁹Stock, L.M.; Brown, H.C. *Adv. Phys. Org. Chem.* **1963**, *1*, 35.

⁹⁰Stock, L.M.; Brown, H.C. *Adv. Phys. Org. Chem.* **1963**, *1*, 35, see p. 45.

⁹¹At least some of these may arise from migration of groups already on the ring; see Olah, G.A.; Olah, J.A.; Ohyama, T. *J. Am. Chem. Soc.* **1984**, *106*, 5284.

That is, the more reactive an attacking species, the less preference it has for the para position compared to the meta. If we combine the Hammett–Brown $\sigma^+ \rho$ relationship with the linearity between $\log S_f$ and $\log p_f^{\text{Me}}$ and between $\log S_f$ and $\log m_f^{\text{Me}}$, it is possible to derive the following expressions:

$$\log p_f^{\text{Me}} = \frac{\sigma_p^+}{\sigma_p^+ - \sigma_m^+} S_f$$

$$\log m_f^{\text{Me}} = \frac{\sigma_m^+}{\sigma_p^+ - \sigma_m^+} S_f$$

S_f is related to ρ by

$$S_f = \rho(\sigma_p^+ - \sigma_m^+)$$

The general validity of these equations is supported by a great deal of experimental data on aromatic substitution reactions of toluene. Examples of values for some reactions obtained from these equations are given in Table 11.4.⁹² For other substituents, the treatment works well with groups that, like methyl, are not very polarizable. For more polarizable groups the correlations are sometimes satisfactory and sometimes not, probably because each electrophile in the transition state makes a different demand on the electrons of the substituent group.

Not only are there substrates for which the treatment is poor, but it also fails with very powerful electrophiles; this is why it is necessary to postulate the encounter complex mentioned on p. 664. For example, relative rates of nitration of *p*-xylene, 1,2,4-trimethylbenzene, and 1,2,3,5-tetramethylbenzene were 1.0, 3.7, and 6.4,⁹³ though the extra methyl groups should enhance the rates much more (*p*-xylene itself reacted 295 times faster than benzene). The explanation is that with powerful electrophiles the reaction rate is so rapid (reaction taking place at virtually every

TABLE 11.4. Values of m_f^{Me} , p_f^{Me} , S_f , and ρ for Three Reactions of Toluene⁹²

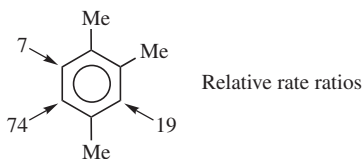

Reaction	m_f^{Me}	p_f^{Me}	S_f	ρ

⁹³Olah, G.A.; Lin, H.C. *J. Am. Chem. Soc.* **1974**, *96*, 2892.

encounter⁹⁴ between an electrophile and substrate molecule)⁹⁵ that the presence of additional activating groups can no longer increase the rate.⁹⁶

Given this behavior (little selectivity in distinguishing between different substrate molecules), the selectivity relationship would predict that positional selectivity should also be very small. However, it is not. For example, under conditions where nitration of *p*-xylene and 1,2,4-trimethylbenzene takes place at about equal rates, there was no corresponding lack of selectivity at positions *within* the latter.⁹⁷ Though

steric effects are about the same at both positions, >10 times as much 5-nitro product was formed as 6-nitro product. It is clear that the selectivity relationship has broken down and it becomes necessary to explain why such an extremely rapid reaction should occur with positional selectivity. The explanation offered is that the rate-determining step is formation of an encounter complex (**12**, p. 664).⁹⁸ Since the position of attachment is not determined in the rate-determining step, the 5:6 ratio is not related to the reaction rate. Essentially the same idea was suggested earlier⁹⁹ and for the same reason (failure of the selectivity relationship in some cases), but the earlier explanation specifically pictured the complex as a π complex, and we have seen (p. 664) that there is evidence against this.

One interesting proposal¹⁰⁰ is that the encounter pair is a radical pair $\text{NO}_2 \cdot \text{ArH} \cdot^+$ formed by an electron transfer (SET), which would explain why the electrophile, once in the encounter complex, can acquire the selectivity that the free NO_2^+ lacked (it is not proposed that a radical pair is present in all aromatic substitutions; only in those that do not obey the selectivity relationship). The radical

pair subsequently collapses to the arenium ion. There is evidence¹⁰¹ both for and against this proposal.¹⁰²

The Effect of the Leaving Group

In the vast majority of aromatic electrophilic substitutions, the leaving group is H^+ as indicated above, and very little work has been done on the relative electrofugal ability of other leaving groups. However, the following orders of leaving-group ability have been suggested:¹⁰³ (1) for leaving groups that depart without assistance ($\text{S}_{\text{N}}1$ process with respect to the leaving group), $\text{NO}_2^+^{104} < i\text{Pr}^+ \sim \text{SO}_3 < t\text{-Bu}^+ \sim \text{ArN}_2^+ < \text{ArCHOH}^+ < \text{NO}^+ < \text{CO}_2$; (2) for leaving groups that depart with assistance from an outside nucleophile ($\text{S}_{\text{N}}2$ process), $\text{Me}^+ < \text{Cl}^+ < \text{Br}^+ < \text{D}^+ \sim \text{RCO}^+ < \text{H}^+ \sim \text{I}^+ < \text{Me}_3\text{Si}^+$. We can use this kind of list to help predict which group, X or Y, will cleave from an arenium ion **30** (see **1**, where $\text{Y} = \text{H}$) once it has been formed, and so obtain an idea of which electrophilic substitutions are feasible. However, a potential leaving group can also affect a reaction in another way: by influencing the rate at which attack of the original electrophile leads to attachment directly at the ipso position. Partial rate factors for electrophilic attack at a position substituted by a group other than hydrogen are called ipso partial rate factors (i_f^{X}).⁵³ Such factors for the nitration of *p*-haloanisoles are 0.18, 0.08, and 0.06, for *p*-iodo-, *p*-bromo-, and *p*-chloroanisole, respectively.¹⁰⁵ This means, for example, that attack at the electrophile in this case leads to attachment at the 4 position of 4-iodoanisole 0.18 times as fast as a single position of benzene. Note that this is far slower than attachment at the 4 position resulting from attack of anisole itself so that the presence of the iodo group greatly slows the reaction at that position. A similar experiment on *p*-cresol showed that ipso

¹⁰¹For evidence in favor of the proposal, see Reents, Jr., W.D.; Freiser, B.S. *J. Am. Chem. Soc.* **1980**, *102*, 271; Morkovnik, A.S.; Dobaeva, N.M.; Panov, V.B.; Okhlobystin, O.Yu. *Doklad. ¹⁰⁴For examples where NO_2^+ is a leaving group (in a migration), see Bullen, J.V.; Ridd, J.H.; Sabek, O. *J. Chem. Soc. Perkin Trans. 2* **1990**, 1681, and other papers in this series.

¹⁰⁵Perrin, C.L.; Skinner, G.A. *J. Am. Chem. Soc.* **1971**, *93*, 3389. See also, Fischer, P.B.; Zollinger, H. *Helv. Chim. Acta* **1972**, *55*, 2139.

attack at the methyl position was 6.8 times slower than attack of phenol leading to attachment at the para position.¹⁰⁶ Thus, in these cases, both an iodo and a methyl group deactivate the ipso position.¹⁰⁷

REACTIONS

The reactions in this chapter are classified according to leaving group. Hydrogen replacements are treated first, then rearrangements in which the attacking entity is first cleaved from another part of the molecule (hydrogen is also the leaving group in these cases), and finally replacements of other leaving groups.

Hydrogen as the Leaving Group in Simple Substitution Reactions

A. Hydrogen as the Electrophile

11-1 Hydrogen Exchange

Deuterio-de-hydrogenation or Deuteriation

Aromatic compounds can exchange hydrogens when treated with acids. The reaction is used chiefly to study mechanistic questions¹⁰⁸ (including substituent effects), but can also be useful to deuterate (add ²H) or tritiate (add ³H) aromatic rings selectively. The usual directive effects apply and, for example, phenol treated with D₂O gives slow exchange on heating, with only ortho and para hydrogens being exchanged.¹⁰⁹ Strong acids, of course, exchange faster with aromatic substrates, and this exchange must be taken into account when studying the mechanism of any aromatic substitution catalyzed by acids. There is a great deal of evidence that exchange takes place by the ordinary arenium ion mechanism. Among the evidence are the orientation effects noted above and the finding that the reaction is general acid catalyzed, which means that a proton is transferred in the slow step¹¹⁰ (p. 373). Furthermore, many examples have been reported of stable solutions of arenium ions formed by attack of a proton on an aromatic ring.⁴ Simple aromatic compounds can be extensively deuterated in a convenient fashion by

treatment with D_2O and BF_3 .¹¹¹ It has been shown that tritium exchange takes place readily at the 2 position of **31**, despite the fact that this position is hindered by the bridge. The rates were not very different from the comparison compound 1,3-dimethylnaphthalene.¹¹²

Hydrogen exchange can also be effected with strong bases,¹¹³ such as NH_2^- . In these cases, the slow step is the proton transfer:

so the S_E1 mechanism and not the usual arenium ion mechanism is operating.¹¹⁴ Aromatic rings can also be deuterated by treatment with D_2O and a rhodium(III) chloride¹¹⁵ or platinum¹¹⁶ catalyst or with C_6D_6 and an alkylaluminum dichloride catalyst,¹¹⁷ though rearrangements may take place during the latter procedure. Tritium (3H , abbreviated T) can be introduced by treatment with T_2O and an alkylaluminum dichloride catalyst.¹¹⁷ Tritiation at specific sites (e.g., >90% para in toluene) has been achieved with T_2 gas and a microporous aluminophosphate catalyst.¹¹⁸

Most aromatic compounds, whether of high or low reactivity, can be nitrated, because a wide variety of nitrating agents is available.¹¹⁹ For benzene, the simple alkylbenzenes, and less reactive compounds, the most common reagent is a mixture of concentrated nitric and sulfuric acids,¹²⁰ but for active substrates, the reaction can be carried out with nitric acid alone,¹²¹ or in water, acetic acid, acetic anhydride, or chloroform.¹²² Nitric acid in acetic anhydride/trifluoroacetic anhydride on zeolite H- β was used to convert toluene to 2,4-dinitrotoluene,¹²³ and AcONO₂ on clay converted ethylbenzene to ortho-para nitro ethylbenzene.¹²⁴ In fact, these milder conditions are necessary for active compounds, such as amines, phenols, and pyrroles, since reaction with mixed nitric and sulfuric acids would oxidize these substrates. With active substrates, such as amines and phenols, nitration can be accomplished by nitrosation under oxidizing conditions with a mixture of dilute nitrous and nitric acids.¹²⁵ A mixture of NO₂/O₂/Fe(acac)₃ can be used for active compounds,¹²⁶ as can NaNO₂ with trichloroisocyanuric acid on wet silica gel,¹²⁷ or N₂O₄ and silica acetate.¹²⁸ Trimethoxybenzenes were nitrated easily with ceric ammonium nitrate on silica gel,¹²⁹ and mesitylene was nitrated in an

ionic liquid using nitric acid–acetic anhydride.¹³⁰ Phenol can be nitrated in an ionic liquid.¹³¹

If anhydrous conditions are required, nitration can be effected with N_2O_5 ¹³² in CCl_4 in the presence of P_2O_5 , which removes the water formed in the reaction.¹³³ These reagents can also be used with proton or Lewis acid catalysts. Representative nitrating agents are NaNO_2 and trifluoroacetic acid,¹³⁴ N_2O_4 (which gives good yields with polycyclic hydrocarbons¹³⁵), $\text{N}_2\text{O}_4/\text{O}_2$ and a catalytic amount of zeolite $\text{H}\beta$,¹³⁶ $\text{Yb}(\text{OTf})_3$,¹³⁷ and nitronium salts,¹³⁸ such as $\text{NO}_2^+\text{BF}_4^-$, $\text{NO}_2^+\text{PF}_6^-$, and $\text{NO}_2^+\text{CF}_3\text{SO}_3^-$.¹³⁹ A mixture of NO_2 and ozone has also been used.¹⁴⁰ Clays, such as clay-supported cupric nitrate (Claycop),^{141,142} or Montmorillonite $\text{KSF-Bi}(\text{NO}_3)$ ¹⁴³ can be used to nitrate aromatic rings. Nitration of styrene poses a problem since addition occurs to the $\text{C}=\text{C}$ unit to give a 1-nitroethyl aryl.¹⁴⁴ Heterocycles, such as pyridine, are nitrated with N_2O_5 and SO_2 .¹⁴⁵ Deactivated aromatic rings, as in acetophenone, were nitrated with N_2O_5 and $\text{Fe}(\text{acac})_2$.¹⁴⁶

An alternative route for the nitration of activated aromatic compounds, such as anisole, used a nitrate ester (RONO₂) with triflic acid in an ionic liquid for ortho-selective nitration.¹⁴⁷ Nitration in alkaline media can be accomplished with esters of nitric acid, such as ethyl nitrate (EtONO₂).

When anilines are nitrated under strong acid conditions, meta orientation is generally observed, because the species undergoing nitration is actually the conjugate acid of the amine. If the conditions are less acidic, the free amine is nitrated and the orientation is ortho–para. Although the free base may be present in much smaller amounts than the conjugate acid, it is far more susceptible to aromatic substitution (see also p. 668). Because of these factors and because they are vulnerable to oxidation by nitric acid, primary aromatic amines are often protected before nitration by treatment with acetyl chloride (**16-72**) or acetic anhydride (**16-73**). Nitration of the resulting acetanilide derivative avoids all these problems. There is evidence that when the reaction takes place on the free amine, it is the nitrogen that is attacked to give an *N*-nitro compound Ar–NH–NO₂ which rapidly undergoes rearrangement (see **11-28**) to give the product.¹⁴⁸

Since the nitro group is deactivating, it is usually easy to stop the reaction after one group has entered the ring, but a second and a third group can be introduced if desired, especially when an activating group is also present. Even *m*-dinitrobenzene can be nitrated if vigorous conditions are applied. This has been accomplished with NO₂⁺BF₄⁻ in FSO₃H at 150°C.¹⁴⁹

With most of the reagents mentioned, the attacking species is the nitronium ion NO₂⁺. Among the ways in which this ion is formed are

1. In concentrated sulfuric acid, by an acid–base reaction in which nitric acid is the base:

This ionization is essentially complete.

2. In concentrated nitric acid alone,¹⁵⁰ by a similar acid–base reaction in which one molecule of nitric acid is the acid and another the base:

This equilibrium lies to the left (~4% ionization), but enough NO₂⁺ is formed for nitration to occur.

¹⁵⁰See Belson, D.J.; Strachan, A.N. *J. Chem. Soc. Perkin Trans. 2* **1989**, 15.

3. The equilibrium just mentioned occurs to a small extent even in organic solvents.
4. With N_2O_5 in CCl_4 , there is spontaneous dissociation:

but in this case there is evidence that some nitration also takes place with undissociated N_2O_5 as the electrophile.

5. When nitronium salts are used, NO_2^+ is of course present to begin with. Esters and acyl halides of nitric acid ionize to form NO_2^+ . Nitrocyclohexadienones are converted to NO_2^+ and the corresponding phenol.¹³²

There is a great deal of evidence that NO_2^+ is present in most nitration reactions and that it is the attacking entity,¹⁵¹ for example,

1. Nitric acid has a peak in the Raman spectrum. When nitric acid is dissolved in concentrated sulfuric acid, the peak disappears and two new peaks appear, one at 1400 cm^{-1} attributable to NO_2^+ and one at 1050 cm^{-1} due to HSO_4^- .¹⁵²
2. On addition of nitric acid, the freezing point of sulfuric acid is lowered about four times the amount expected if no ionization has taken place.¹⁵³ This means that the addition of one molecule of nitric acid results in the production of four particles, which is strong evidence for the ionization reaction between nitric and sulfuric acids given above.
3. The fact that nitronium salts in which nitronium ion is known to be present (by X-ray studies) nitrate aromatic compounds shows that this ion does attack the ring.
4. The rate of the reaction with most reagents is proportional to the concentration of NO_2^+ , not to that of other species.¹⁵⁴ When the reagent produces this ion in small amounts, the attack is slow and only active substrates can be nitrated. In concentrated and aqueous mineral acids, the kinetics are second order: first order each in aromatic substrate and in nitric acid (unless pure nitric acid is used in which case there are pseudo-first-order kinetics). But in organic solvents such as nitromethane, acetic acid, and CCl_4 , the kinetics are first order in nitric acid alone and zero order in aromatic substrate, because the rate-determining step is formation of NO_2^+ and the substrate does not take part in this.

¹⁵¹For an exhaustive study of this reaction, see Hughes, E.D.; Ingold, C.K. in a series of several papers with several different co-workers, see *J. Chem. Soc.* **1950**, 2400.

¹⁵⁴This is not always strictly true. See Ross, D.S.; Kuhlmann, K.F.; Malhotra, R. *J. Am. Chem. Soc.* **1983**, *105*, 4299.

An interesting route to nitrobenzene begins with bromobenzene. Reaction with butyllithium gives phenyllithium, which reacts with an excess of N_2O_4 to give nitrobenzene.¹⁵⁵

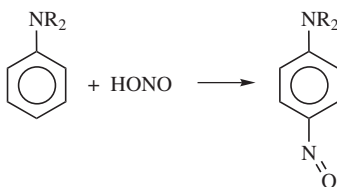

In a few cases, depending on the substrate and solvent, there is evidence that the arenium ion is not formed directly, but via the intermediacy of a radical pair (see p. 682) such as **32**.¹⁵⁶

Arylboronic acids have been shown to react with ammonium nitrate and trifluoroacetic acid to give the corresponding nitrobenzene.¹⁵⁷

11-3 Nitrosation or Nitroso-de-hydrogenation

Ring nitrosation¹⁵⁸ with nitrous acid is normally carried out only with active substrates, such as amines and phenols. However, primary aromatic amines give diazonium ions (**13-19**) when treated with nitrous acid,¹⁵⁹ and secondary amines tend to give *N*-nitroso rather than *C*-nitroso compounds (**12-50**); hence this reaction is normally limited to phenols and tertiary aromatic amines. Nevertheless, secondary aromatic amines can be *C*-nitrosated in two ways. The *N*-nitroso compound first obtained can be isomerized to a *C*-nitroso compound (**11-29**), or it can be treated with another equivalent of nitrous acid to give an *N,C*-dinitroso compound. Also, a successful nitrosation of anisole has been reported, where the solvent was $\text{CF}_3\text{COOH}-\text{CH}_2\text{Cl}_2$.¹⁶⁰

Much less work has been done on the mechanism of this reaction than on **11-2**.¹⁶¹ In some cases, the attacking entity is NO^+ , but in others it is apparently NOCl , NOBr , N_2O_3 , and so on, in each of which there is a carrier of NO^+ . Both NOCl and NOBr are formed during the normal process of making nitrous acid (the treatment of sodium nitrite with HCl or HBr). Nitrosation requires active substrates because NO^+ is much less reactive than NO_2^+ . Kinetic studies have shown that NO^+ is at least 10^{14} times less reactive than NO_2^+ .¹⁶² A consequence of the relatively high stability of NO^+ is that this species is easily cleaved from the arenium ion, so that k_{-1} competes with k_2 (p. 660) and isotope effects are found.¹⁶³ With phenols, there is evidence that nitrosation may first take place at the OH group, after which the nitrite ester thus formed rearranges to the C-nitroso product.¹⁶⁴ Tertiary aromatic amines substituted in the ortho position generally do not react with HONO , probably because the ortho substituent prevents planarity of the dialkylamino group, without which the ring is no longer activated. This is an example of steric inhibition of resonance (p. 48).

OS I, 214, 411, 511; II, 223; IV, 247.

11-4 Diazonium Coupling

Arylazo-de-hydrogenation

Aromatic diazonium ions normally couple only with active substrates, such as amines and phenols.¹⁶⁵ Many of the products of this reaction are used as dyes (*azo dyes*).¹⁶⁶ Presumably because of the size of the attacking species, substitution is mostly para to the activating group, unless that position is already occupied, in which case ortho substitution takes place. The pH of the solution is important both for phenols and amines. For amines, the solutions may be mildly acidic or neutral. The fact that amines give ortho and para products shows that even in mildly acidic solution they react in their un-ionized form. If the acidity is too high, the reaction does not occur, because the concentration of free amine becomes too small. Phenols must be coupled in slightly alkaline solution where they are converted to the more reactive phenoxide ions, because phenols themselves are not active enough for the

¹⁶⁶For reviews of azo dyes, see Zollinger, H. *Color Chemistry*, VCH, NY, **1987**, pp. 85–148; Gordon, P.F.; Gregory, P. *Organic Chemistry in Colour*, Springer, NY, **1983**, pp. 95–162.

reaction. However, neither phenols nor amines react in moderately alkaline solution, because the diazonium ion is converted to a diazo hydroxide Ar-N=O^- . Primary and secondary amines face competition from attack at the nitrogen.¹⁶⁷ However, the resulting *N*-azo compounds (aryl triazenes) can be isomerized to *C*-azo compounds (**11-30**). In at least some cases, even when the *C*-azo compound is isolated, it is the result of initial *N*-azo compound formation followed by isomerization. It is therefore possible to synthesize the *C*-azo compound directly in one laboratory step.¹⁶⁸ Acylated amines and phenolic ethers and esters are ordinarily not active enough for this reaction, though it is sometimes possible to couple them (as well as such polyalkylated benzenes as mesitylene and pentamethylbenzene) to diazonium ions containing electron-withdrawing groups in the para position, since such groups increase the concentration of the positive charge and thus the electrophilicity of the ArN_2^+ . Some coupling reactions which are otherwise very slow (in cases where the coupling site is crowded) are catalyzed by pyridine for reasons discussed on p. 661. Phase transfer catalysis has also been used.¹⁶⁹

Coupling of a few aliphatic diazonium compounds to aromatic rings has been reported. All the examples reported so far involve cyclopropanediazonium ions and bridgehead diazonium ions, in which loss of N_2 would lead to very unstable carbocations.¹⁷⁰ Azobenzenes have been prepared by Pd-catalyzed coupling of aryl halozides with aryl halides, followed by direct oxidation.¹⁷¹

The mechanism of *Z/E* isomerization in Ar-N=NAr systems has been studied.¹⁷² OS I, 49, 374; II, 35, 39, 145.

11-5 Direct Introduction of the Diazonium Group

Diazonation or Diazo-de-hydrogenation

Diazonium salts can be prepared directly by replacement of an aromatic hydrogen without the necessity of going through the amino group.¹⁷³ The reaction is essentially limited to active substrates (amines and phenols), since otherwise poor yields are obtained. Since the reagents and the substrate are the same as in reaction **11-3**, the first species formed is the nitroso compound. In the presence of excess nitrous acid, this is converted to the diazonium ion.¹⁷⁴ The reagent

(azidochloromethylene)dimethylammonium chloride $[\text{Me}_2\text{N}=\text{C}(\text{Cl})\text{N}_3 \text{Cl}^-]$ can also introduce the diazonium group directly into a phenol.¹⁷⁵ A synthesis of solid aryl diazonium chlorides is now available.¹⁷⁶

11-6 Amination or Amino-de-hydrogenation¹⁷⁷

Aromatic compounds can be converted to primary aromatic amines, in 10–65% yields, by treatment with hydrazoic acid HN_3 in the presence of AlCl_3 or H_2SO_4 .¹⁷⁸ Higher yields (>90%) have been reported with trimethylsilyl azide (Me_3SiN_3) and triflic acid $\text{F}_3\text{CSO}_2\text{OH}$.¹⁷⁹ Treatment of an aromatic compound with tetramethylhydrazonium iodide and then ammonium also give the aryl amine.¹⁸⁰ Tertiary amines have been prepared in ~50–90% yields by treatment of aromatic hydrocarbons with *N*-chlorodialkylamines; by heating in 96% sulfuric acid; or with AlCl_3 or FeCl_3 in nitroalkane solvents; or by irradiation.¹⁸¹ Treatment of an aryl halide with an amine and a palladium catalyst leads to the aniline derivative.¹⁸²

Tertiary (and to a lesser extent, secondary) aromatic amines can also be prepared in moderate to high yields by amination with an *N*-chlorodialkylamine (or an *N*-chloroalkylamine) and a metallic-ion catalyst (e.g., Fe^{2+} , Ti^{3+} , Cu^+ , Cr^{2+}) in the presence of sulfuric acid.¹⁸³ The attacking species in this case is the aminium radical ion $\text{R}_2\text{NH}\bullet$ formed by¹⁸⁴

Because attack is by a positive species (even though it is a free radical), orientation is similar to that in other electrophilic substitutions (e.g., phenol and acetanilide give ortho and para substitution, mostly para). When an alkyl group is present, attack at the benzylic position competes with ring substitution. Aromatic rings containing only meta-directing groups do not give the reaction at all. Fused ring systems react well.¹⁸⁵

¹⁸⁴For a review of aminium radical ions, see Chow, Y.L. *React. Intermed. (Plenum)* **1980**, *1*, 151.

¹⁸⁵The reaction has been extended to the formation of primary aromatic amines, but the scope is narrow: Citterio, A.; Gentile, A.; Minisci, F.; Navarrini, V.; Serravalle, M.; Ventura, S. *J. Org. Chem.* **1984**, *49*, 4479.

Unusual orientation has been reported for amination with haloamines and with NCl_3 in the presence of AlCl_3 . For example, toluene gave predominately meta amination.¹⁸⁶ It has been suggested that initial attack in this case is by Cl^+ and that a nitrogen nucleophile (whose structure is not known, but is represented here as NH_2^- for simplicity) adds to the resulting arenium ion, so that the initial reaction is addition to a carbon-carbon double bond followed by elimination of HCl from **33**.¹⁸⁷

According to this suggestion, the electrophilic attack is at the para position (or the ortho, which leads to the same product) and the meta orientation of the amino group arises indirectly. This mechanism is called the σ -substitution mechanism.

Diphenyliodonium salts react with amines in the presence of a copper catalyst. Diphenyliodonium tetrafluoroborate, $\text{Ph}_2\text{I}^+\text{BF}_4^-$, reacts with indole in DMF at 150°C with a $\text{Cu}(\text{OAc})_2$ catalyst, for example, to give *N*-phenylindole.¹⁸⁸

Aromatic compounds that do not contain meta-directing groups can be converted to diarylamines by treatment with aryl azides in the presence of phenol at -60°C : $\text{ArH} + \text{Ar}'\text{N}_3 \rightarrow \text{ArNHAr}'$.¹⁸⁹ Diarylamines are also obtained by the reaction of *N*-arylhydroxylamines with aromatic compounds (benzene, toluene, anisole) in the presence of F_3CCOOH : $\text{ArH} + \text{Ar}'\text{NHOH} \rightarrow \text{ArNHAr}'$.¹⁹⁰

Direct amidation can be carried out if an aromatic compound is heated with a hydroxamic acid (**34**) in polyphosphoric acid, but the scope is essentially limited to phenolic ethers.¹⁹¹ The reaction of an aromatic compound with aniline, Bu_4NF and KMnO_4 led to the diarylamine.¹⁹² The formation of hydroindole derivatives was accomplished by reaction of a *N*-carbamoyl phenylethylamine derivative with phenyliodine (III) diacetate, followed by Bu_4NF .¹⁹³ Direct amidation via ipso substitution by nitrogen was accomplished when a *N*-methoxy arylethylamide (**35**) was

C. Sulfur Electrophiles

11-7 Sulfonation or Sulfo-de-hydrogenation

The sulfonation reaction is very broad in scope and many aromatic hydrocarbons (including fused ring systems), aryl halides, ethers, carboxylic acids, amines,¹⁹⁷ acylated amines, ketones, nitro compounds, and sulfonic acids have been sulfonated.¹⁹⁸ Phenols can also be successfully sulfonated, but attack at oxygen may compete.¹⁹⁹ Sulfonation is often accomplished with concentrated sulfuric acid, but it can also be done with fuming sulfuric acid, SO_3 , ClSO_2OH , $\text{ClSO}_2\text{NMe}_2/\text{In}(\text{OTf})_3$,²⁰⁰ or other reagents.²⁰¹ As with nitration (**11-2**), reagents of a wide variety of activity are available to suit both highly active and highly inactive substrates. Since this is a reversible reaction (see **11-38**), it may be necessary to drive the reaction to completion.

²⁰⁰Frost, C.G.; Hartley, J.P.; Griffin, D. *Synlett* **2002**, 1928.

²⁰¹For a reaction using silica sulfuric acid, see Hajipour, A.R.; Mirjalili, B.B.F.; Zarei, A.; Khazdooz, L.; Ruoho, A.E. *Tetrahedron Lett.* **2004**, *45*, 6607.

However, at low temperatures the reverse reaction is very slow and the forward reaction is practically irreversible.²⁰² Sulfur trioxide reacts much more rapidly than sulfuric acid with benzene it is nearly instantaneous. Sulfones are often side products. When sulfonation is carried out on a benzene ring containing four or five alkyl and/or halogen groups, rearrangements usually occur (see 11-36).

A great deal of work has been done on the mechanism,²⁰³ chiefly by Cerfontain and co-workers. Mechanistic study is made difficult by the complicated nature of the solutions. Indications are that the electrophile varies with the reagent, though SO_3 is involved in all cases, either free or combined with a carrier. In aqueous H_2SO_4 solutions, the electrophile is thought to be H_3SO_4^+ (or a combination of H_2SO_4 and H_3O^+) at concentrations below $\sim 80\text{--}85\%$ H_2SO_4 , and $\text{H}_2\text{S}_2\text{O}_7$ (or a combination of H_2SO_4 and SO_3) at concentrations higher than this²⁰⁴ (the change-over point varies with the substrate²⁰⁵). Evidence for a change in electrophile is that in the dilute and in the concentrated solutions the rate of the reaction was proportional to the activity of H_3SO_4^+ and $\text{H}_2\text{S}_2\text{O}_7$, respectively. Further evidence is that with toluene as substrate the two types of solution gave very different ortho/para ratios. The mechanism is essentially the same for both electrophiles and may be shown as:²⁰⁴

The other product of the first step is HSO_4^- or H_2O from $\text{H}_2\text{S}_2\text{O}_7$ or H_3SO_4^+ , respectively. Path *a* is the principal route, except at very high H_2SO_4 concentrations, when path *b* becomes important. With H_3SO_4^+ the first step is rate determining under all conditions, but with $\text{H}_2\text{S}_2\text{O}_7$ the first step is the slow step only up to $\sim 96\%$ H_2SO_4 , when a subsequent proton transfer becomes partially rate determining.²⁰⁶ The $\text{H}_2\text{S}_2\text{O}_7$ is more reactive than H_3SO_4^+ . In fuming sulfuric acid (H_2SO_4 containing excess SO_3), the electrophile is thought to be $\text{H}_3\text{S}_2\text{O}_7^+$ (protonated $\text{H}_2\text{S}_2\text{O}_7$) up to

~104% H₂SO₄ and H₂S₄O₁₃ (H₂SO₄ + 3SO₃) beyond this concentration.²⁰⁷ Finally, when pure SO₃ is the reagent in aprotic solvents, SO₃ itself is the actual electrophile.²⁰⁸ Free SO₃ is the most reactive of all these species, so that attack here is generally fast and a subsequent step is usually rate determining, at least in some solvents.

11-8 Halosulfonation or Halosulfo-de-hydrogenation

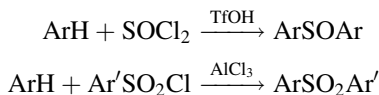

Aromatic sulfonyl chlorides can be prepared directly, by treatment of aromatic rings with chlorosulfuric acid.²⁰⁹ Since sulfonic acids can also be prepared by the same reagent (11-7), it is likely that they are intermediates, being converted to the halides by excess chlorosulfuric acid.²¹⁰ The reaction has also been effected with bromo- and fluorosulfuric acids. Sulfinyl chlorides (ArSOCl) have been prepared by the reaction of thionyl chloride and an aromatic compound on Montmorillonite K10 clay.²¹¹

OS I, 8, 85.

11-9 Sulfonylation

Alkylsulfonylation or Alkylsulfo-de-hydrogenation

Diaryl sulfoxides can be prepared by the reaction of aromatic compounds with thionyl chloride and triflic acid.²¹² Diaryl sulfones have also been prepared using thionyl chloride with the ionic liquid [bmim]Cl•AlCl₃.²¹³ Diaryl sulfones can be formed by treatment of aromatic compounds with aryl sulfonyl chlorides and a Friedel–Crafts catalyst²¹⁴ This reaction is analogous to Friedel–Crafts acylation with carboxylic acid halides (11-17). In a better procedure, the aromatic compound

D. Halogen Electrophiles

11-10 Halogenation²²⁴

Halo-de-hydrogenation

1. *Chlorine and Bromine.* Aromatic compounds can be brominated or chlorinated by treatment with bromine or chlorine in the presence of a catalyst. For amines and phenols the reaction is so rapid that it is carried out with a dilute solution of Br₂ or Cl₂ in water at room temperature, or with aqueous HBr in DMSO.²²⁵ Even so, with amines it is not possible to stop the reaction before all the available ortho and para positions are substituted, because the initially formed haloamines are weaker bases than the original amines and are less

likely to be protonated by the liberated HX.²²⁶ For this reason, primary amines are often converted to the corresponding anilides if monosubstitution is desired. With phenols it is possible to stop after one group has entered.²²⁷ The rapid room-temperature reaction with amines and phenols is often used as a test for these compounds.

For less activated aromatic rings, iron was commonly used at one time for halogenation, but the real catalyst was shown not to be the iron itself, but rather the ferric bromide or ferric chloride formed in small amounts from the reaction between iron and the reagent. Indeed, ferric chloride and other Lewis acids are typically directly used as catalysts, as is iodine. For active substrates, including amines, phenols, naphthalene, and polyalkylbenzenes,²²⁸ such as mesitylene and isodurene, no catalyst is needed. Many Lewis acids can be used, including thallium(III) acetate, which promotes bromination with high regioselectivity para to an ortho-para-directing group.²²⁹ A mixture of Mn(OAc)₃ and acetyl chloride, with ultrasound, chlorinates anisole with high selectivity.²³⁰ Bromination on NaY zeolite occurs with high para selectivity.²³¹

Other acids can be used to promote chlorination or bromination. *N*-Bromosuccinimide and HBF₄ can be used to brominate phenols with high para-selectivity,²³² as can pyridinium bromide perbromide,²³³ and NBS in acetic acid with ultrasound is effective.²³⁴ The use of NBS with a catalytic amount of HCl has also been reported.²³⁵ Both NCS and NBS with aqueous BF₃ gave the respective chloride or bromide.²³⁶ Note that NBS in an ionic liquid²³⁷ gave the brominated aromatic. Bromine on silica gel gave good yields of the brominated aromatic compound.²³⁸ HBr with hydrogen peroxide

²²⁶Monobromination (para) of aromatic amines has been achieved with tetrabutylammonium tribromide: Berthelot, J.; Guette, C.; Desbène, P.; Basselier, J.; Chaquin, P.; Masure, D. *Can. J. Chem.* **1989**, *67*, 2061. For another procedure, see Onaka, M.; Izumi, Y. *Chem. Lett.* **1984**, 2007.

converted aniline to 2,4,6-tribromoaniline.²³⁹ Majetich and co-workers reported the use of HBr/DMSO for the remarkably selective bromination of aniline.²⁴⁰ *para*-Bromination of aniline was reported by mixing aniline with the ionic liquid, bmim Br₃.²⁴¹ Similarly, hmim Br₃²⁴² without another reagent is a brominating agent.

Other reagents have been used for chlorination and bromination, among them HOCl,²⁴³ HOBr, and *N*-chloro and *N*-bromo amides (especially NBS and tetraalkylammonium polyhalides²⁴⁴). In all but the last of these cases, the reaction is catalyzed by the addition of acids. Sulfuryl chloride (SO₂Cl₂) in acetic acid effectively chlorinates anisole derivatives,²⁴⁵ and LiBr with ceric ammonium nitrate in acetonitrile brominates.²⁴⁶ Acetyl chloride with a catalytic amount of ceric ammonium nitrate also converted aromatic compounds to the corresponding chlorinated derivative.²⁴⁷ A mixture of KCl and Oxone[®] as chlorinated activated aromatic compounds.²⁴⁸ Oxone[®] and KBr gave good *para* bromination of anisole.²⁴⁹ Dibromoisocyanuric acid in H₂SO₄ is a very good brominating agent²⁵⁰ for substrates with strongly deactivating substituents.²⁵¹ If the substrate contains alkyl groups, side-chain halogenation (**14-1**) is possible with most of the reagents mentioned, including chlorine and bromine. Since side-chain halogenation is catalyzed by light, the reactions should be run in the absence of light wherever possible. Both NCS in isopropanol²⁵² and *tert*-butyl hypochlorite²⁵³ chlorinate aniline derivatives, and KBr/NaBO₃•4 H₂O has been used for the bromination of aniline derivatives.²⁵⁴ Anisole was brominated with *para* selectivity using HBr, in the presence of *tert*-butyl hydroperoxide and hydrogen peroxide.²⁵⁵ Potassium bromide (KBr) with a zeolite (HZSM-5), acetic acid and 30% hydrogen peroxide was used to brominate both anisole and aniline derivatives.²⁵⁶ Conversion of aniline to the *N*-SnMe₃ derivative allowed

in situ bromination with bromine, with high para selectivity after conversion to the free amine with aqueous KF .²⁵⁷ Pyridinium bromochromate converted phenolic derivatives to brominated phenols.²⁵⁸

Chlorine is a more active reagent than bromine. Phenols can be brominated exclusively in the ortho position (disubstitution of phenol gives 2,6-dibromophenol) by treatment with Br_2 at about -70°C , in the presence of *tert*-butylamine or triethylenediamine to precipitate out the liberated HBr .²⁵⁹ Predominant ortho chlorination²⁶⁰ of phenols has been achieved with chlorinated cyclohexadienes,²⁶¹ while para chlorination of phenols, phenolic ethers, and amines can be accomplished with *N*-chloroamines²⁶² and with *N*-chlorodimethylsulfonium chloride ($\text{Me}_2\text{S}^+\text{ClCl}^-$).²⁶³ The last method is also successful for bromination when *N*-bromodimethylsulfonium bromide is used. On the other hand, certain alkylated phenols can be brominated in the meta positions with Br_2 in the superacid solution $\text{SbF}_5\text{--HF}$.²⁶⁴ It is likely that the meta orientation is the result of conversion by the super acid of the OH group to the OH_2^+ group, which should be meta directing because of its positive charge. Bromination and the Sandmeyer reaction (**14-20**) can be carried out in one laboratory step to give **37** by treatment of an aromatic primary amine with CuBr_2 and *tert*-butyl nitrite, for example²⁶⁵

With deactivated aromatic derivatives, such as nitrobenzene, BrF_3 and Br_2 is an effective reagent, gives the *meta*-brominated product.²⁶⁶ Tetrabutylammonium bromide and P_2O_5 at 100°C has been used to convert 2-hydroxypyridine derivatives to the corresponding 2-bromopyridine.²⁶⁷ Bromination at C-6 of 2-aminopyridine was accomplished with NBS.²⁶⁸ An alternative route

reacted pyridine *N*-oxide was POCl₃ and triethylamine to give 2-chloropyridine.²⁶⁹ Pyridinium dichlorobromate with FeCl₃ brominates benzene.²⁷⁰

For reactions in the absence of a catalyst, the attacking entity is simply Br₂ or Cl₂ that has been polarized by the ring.²⁷¹

Evidence for molecular chlorine or bromine as the attacking species in these cases is that acids, bases, and other ions, especially chloride ion, accelerate the rate about equally, though if chlorine dissociated into Cl⁺ and Cl⁻, the addition of chloride should decrease the rate and the addition of acids should increase it. Intermediate **38** has been detected spectrally in the aqueous bromination of phenol.²⁷²

When a Lewis acid catalyst is used with chlorine or bromine, the attacking entity may be Cl⁺ or Br⁺, formed by FeCl₃ + Br₂ → FeCl₃Br⁻ + Br⁺, or it may be Cl₂ or Br₂, polarized by the catalyst. With other reagents, the attacking entity in brominations may be Br⁺ or a species, such as H₂OBr⁺ (the conjugate acid of HOBr), in which H₂O is a carrier of Br⁺.²⁷³ With HOCl in water the electrophile may be Cl₂O, Cl₂, or H₂OCl⁺; in acetic acid it is generally AcOCl. All these species are more reactive than HOCl itself.²⁷⁴ It is extremely doubtful that Cl⁺ is a significant electrophile in chlorinations by HOCl.²⁷⁴ It has been demonstrated in the reaction between *N*-methylaniline and calcium hypochlorite that the chlorine attacking entity attacks the *nitrogen* to give *N*-chloro-*N*-methylaniline, which rearranges (as in **11-31**) to give a mixture of ring-chlorinated *N*-methylanilines in which the ortho isomer predominates.²⁷⁵ In addition to hypohalous acids and metal hypohalites, organic hypohalites are reactive. An example is *tert*-butylhypobromite (*t*-BuOBr), which brominated toluene in the presence of zeolite HNaX.²⁷⁶

When chlorination or bromination is carried out at high temperatures (e.g., 300–400°C), ortho–para-directing groups direct meta and vice versa.²⁷⁷ A different mechanism operates here, which is not completely understood. It is also possible for bromination to take place by the S_E1 mechanism, for example, in the *t*-BuOK-catalyzed bromination of 1,3,5-tribromobenzene.²⁷⁸

Furan and thiophene are known to polymerize in the presence of strong acid, both Brønsted–Lowry and Lewis. For such highly reactive heteroaromatic systems, alternative halogenating reagents are commonly used. Furan was converted to 2-bromofuran with a bromine•dioxane complex, for example, at <0°C.²⁷⁹ 3-Butylthiophene reacted with NBS/acetic acid to give 2-bromo-3-butylthiophene.²⁸⁰ *N*-Methylpyrrole reacted with NBS and a catalytic amount of PBr₃, at –78°C → –10°C, to give *N*-methyl-3-bromopyrrole.²⁸¹

2. **Iodine.** Iodine is the least reactive of the halogens in aromatic substitution.²⁸² Except for active substrates, an oxidizing agent must normally be present to oxidize I₂ to a better electrophile.²⁸³ Examples of such oxidizing agents are HNO₃, HIO₃, SO₃, MnO₂,²⁸⁴ hypervalent iodine compounds, such as PhI(OTf)₂,²⁸⁵ NaIO₄,²⁸⁶ peroxyacetic acid, H₂O₂,²⁸⁷ peroxydisulfates,²⁸⁸ and ammonium iodide with Oxone[®].²⁸⁹ The ICl is a better iodinating agent than iodine itself.²⁹⁰ Among other reagents used have been IF (prepared directly from the elements),²⁹¹ and benzyltrialkylammonium dichloroiodate (which iodinate phenols, aromatic amines, and *N*-acylated aromatic amines,²⁹² as well

as unprotected aniline derivatives²⁹³). Iodination can also be accomplished by treatment of the substrate with NCI and sulfuric acid,²⁹⁴ NIS and trifluoroacetic acid,²⁹⁵ KI/KIO₃ in aqueous methanol,²⁹⁶ I₂ in the presence of copper salts,²⁹⁷ Al₂O₃,²⁹⁸ and NaI with an iron catalyst.²⁹⁹ Sodium periodate and iodine was used to iodinate β -carboline.³⁰⁰ Sodium iodide in liquid NO₂ can be used to iodinate aniline derivatives.³⁰¹ A solvent-free iodination was accomplished using NaCl₂ and an *N*-bromoammonium salt.³⁰² Another solvent-free iodination used I₂ with Bi(NO₃)₃ on silica gel.³⁰³ Iodine with Selectfluor also leads to iodination of aromatic compounds.³⁰⁴

The actual attacking species is less clear than with bromine or chlorine. Iodine itself is too unreactive, except for active species, such as phenols, where there is good evidence that I₂ is the attacking entity.³⁰⁵ There is evidence that AcOI may be the attacking entity when peroxyacetic acid is the oxidizing agent,³⁰⁶ and I₃⁺ when SO₃ or HIO₃ is the oxidizing agent.³⁰⁷ The I⁺ ion has been implicated in several procedures.³⁰⁸ For an indirect method for accomplishing aromatic iodination, see **12-31**.

Note that conversion of aniline derivatives to the corresponding para aryllithium, followed by reaction with B(OMe)₃ and then bromine at -78°C gave *p*-bromoaniline.³⁰⁹

- 3. Fluorine.** Direct fluorination of aromatic rings with F₂ is not feasible at room temperature, because of the extreme reactivity of F₂.³¹⁰ It has been accomplished at low temperatures (e.g., -70 to -20°C, depending on the

substrate),³¹¹ but the reaction is not yet of preparative significance. Fluorination has also been reported with acetyl hypofluorite CH_3COOF (generated from F_2 and sodium acetate),³¹² with XeF_2 ,³¹³ and with an *N*-fluoroperfluoroalkyl sulfonamide, for example $(\text{CF}_3\text{SO}_2)_2\text{NF}$.³¹⁴ Pyridine has been converted to 2-fluoropyridine with $\text{F}_2/\text{I}_2/\text{NET}_3$ in 1,1,2-trichloro-1,2,2-trifluoroethane.³¹⁵ However, none of these methods seems likely to displace the Schiemann reaction (**13-23**; heating diazonium tetrafluoroborates) as the most common method for introducing fluorine into aromatic rings.

The overall effectiveness of reagents in aromatic substitution is $\text{Cl}_2 > \text{BrCl} > \text{Br}_2 > \text{ICl} > \text{I}_2$.

E. Carbon Electrophiles

In the reactions in this section, a new carbon–carbon bond is formed. With respect to the aromatic ring, they are electrophilic substitutions, because a positive species attacks the ring. We treat them in this manner because it is customary. However, with respect to the electrophile, most of these reactions are nucleophilic substitutions, and what was said in Chapter 10 is pertinent to them.

11-11 Friedel–Crafts Alkylation

Alkylation or Alkyl-de-hydrogenation

The alkylation of aromatic rings, called *Friedel–Crafts alkylation*, is a reaction of very broad scope.³¹⁶ The most important reagents are alkyl halides, alkenes, and

³¹⁶For a monograph, see Roberts, R.M.; Khalaf, A.A. *Friedel–Crafts Alkylation Chemistry*, Marcel Dekker, NY, **1984**. For a treatise on Friedel–Crafts reactions in general, see Olah, G.A. *Friedel–Crafts and Related Reactions*, Wiley, NY, **1963–1965**. Volume 1 covers general aspects, such as catalyst activity, intermediate complexes, and so on. Volume 2 covers alkylation and related reactions. In this volume, the various reagents are treated by the indicated authors as follows: alkenes and alkanes, Patinkin, S.H.; Friedman, B.S. pp. 1–288; dienes and substituted alkenes, Koncos, R.; Friedman, B.S. pp. 289–412; alkynes, Franzen, V. pp. 413–416; alkyl halides, Drahowzal, F.A. pp. 417–475; alcohols and ethers, Schriesheim, A. pp. 477–595; sulfonates and inorganic esters, Drahowzal, F.A. pp. 641–658. For a monograph in which five chapters of the above treatise are reprinted and more recent material added, see Olah, G.A. *Friedel–Crafts Chemistry*, Wiley, NY, **1973**.

alcohols, but other types of reagent have also been employed.³¹⁶ Tertiary halides are particularly good substrates since they form relatively stable tertiary carbocations. *tert*-Butyl chloride reacts with phenetole in the presence of a $\text{ReBr}(\text{CO})_5$ catalyst, for example, to give the 4-*tert*-butyl isomer as the major product.³¹⁷ When alkyl halides are used, the reactivity order is $\text{F} > \text{Cl} > \text{Br} > \text{I}$.³¹⁸ This trend can be seen in reactions of dihalo compounds, such as $\text{FCH}_2\text{CH}_2\text{CH}_2\text{Cl}$, which react with benzene to give $\text{PhCH}_2\text{CH}_2\text{CH}_2\text{Cl}$ ³¹⁹ when the catalyst is BCl_3 . By the use of this catalyst, it is therefore possible to place a haloalkyl group on a ring (see also, **11-14**).³²⁰ Di- and trihalides, when all the halogens are the same, usually react with more than one molecule of an aromatic compound; it is usually not possible to stop the reaction earlier.³²¹ Thus, benzene with CH_2Cl_2 gives not PhCH_2Cl , but Ph_2CH_2 ; benzene with CHCl_3 gives Ph_3CH . With CCl_4 , however, the reaction stops when only three rings have been substituted to give Ph_3CCl . Functionalized alkyl halides, such as $\text{ClCH}(\text{SEt})\text{CO}_2\text{Et}$, undergo Friedel–Crafts alkylation.³²² Interestingly, benzyl chloride was converted to diphenylmethane in benzene at 130°C with 10 atm of CO ,³²³ and also with a $\text{LiB}(\text{C}_6\text{F}_5)_4$ catalyst.³²⁴

Alkenes are especially good alkylating agents, generally proceeding by formation of an intermediate carbocation that reacts with the electron rich aromatic ring, and the final product (**39**) incorporates a H and Ar from ArH to a $\text{C}=\text{C}$ double bond. Many variations are possible. This reaction has been accomplished in an ionic liquid, using $\text{Sc}(\text{OTf})_3$ as the catalyst.³²⁵ Intramolecular versions lead to polycyclic aromatic compounds.³²⁶ Benzene reacted with 1,2,3,6-tetrahydropyridine in the presence of trifluoromethanesulfonic acid to give 4-phenylpiperidine.³²⁷

When 4-methoxyphenol reacted with isobutylene (electrolysis with 3 M LiClO₄ in nitromethane and acetic acid, initial reaction with the phenolic oxygen generated an ether moiety and the resulting carbocation was attacked by the aromatic ring to form a benzofuran.³²⁸ Acetylene reacts with 2 mol of aromatic compound to give 1,1-diarylethanes, and phenylacetylene reacted to give 1,1-diarylethenes with a Sc(OTf)₃ catalyst.³²⁹ Variations are possible here as well. Phenol reacted with trimethylsilylethyne, in the presence of SnCl₄ and 50% BuLi, at 105°C, to give the 2-vinyl phenolic derivative.³³⁰ A palladium-catalyzed reaction of ethyl propiolate and *p*-xylene, with trifluoroacetic acid, gave the 3-arylalkenyl ester.³³¹ A ruthenium catalyzed intramolecular reaction with a pendant alkyne unit led to a dihydronaphthalene derivative.³³²

Alcohols are more active than alkyl halides, but if a Lewis acid catalyst is used more catalyst is required, since the catalyst complexes with the OH group. However, proton acids, such as H₂SO₄, are often used to catalyze alkylation with alcohols. An intramolecular cyclization was reported from an allylic alcohol, using P₂O₅, to give indene derivatives.³³³ When carboxylic esters are the reagents, there is competition between alkylation and acylation (11-17). This competition can often be controlled by choice of catalyst, and alkylation is usually favored, but carboxylic esters are not often employed in Friedel-Crafts reactions. Other alkylating agents are ethers, thiols, sulfates, sulfonates, alkyl nitro compounds,³³⁴ and even alkanes and cycloalkanes, under conditions where these are converted to carbocations. Notable here are ethylene oxide, which puts the CH₂CH₂OH group onto the ring,³³⁵ and cyclopropyl³³⁶ units. For all types of reagent the reactivity order is allylic ~ benzylic > tertiary > secondary > primary.

Regardless of which reagent is used, a catalyst is nearly always required.³³⁷ Aluminum chloride and boron trifluoride are the most common, but many other Lewis acids have been used, and also proton acids, such as HF and H₂SO₄.³³⁸ For active halides a trace of a less active catalyst, such as ZnCl₂, may be enough. For an unreactive halide, such as chloromethane, a more powerful catalyst, such as AlCl₃, is needed, and in larger amounts. In some cases, especially with alkenes, a Lewis acid catalyst causes reaction only if a small amount of proton-donating cocatalyst is present. Catalysts have been arranged in the following order of overall reactivity: AlBr₃ > AlCl₃ > GaCl₃ > FeCl₃ > SbCl₅³³⁹ > ZrCl₄, SnCl₄ > BCl₃, BF₃, SbCl₃,³⁴⁰ but the reactivity order in each case depends on the substrate, reagent, and conditions.

Alkyl mesylates undergo alkylation reaction with benzene rings in the presence of Sc(OTf)₃.³⁴¹ Allylic acetates undergo alkylation with Mo(CO)₆³⁴² and allylic chlorides react in the presence of ZnCl₂/SiO₂.³⁴³ Montmorillonite clay (K10) is an effective medium for alkylation reactions.³⁴⁴ Nafion-H, a super acidic perfluorinated resin sulfonic acid, is a very good catalyst for gas phase alkylations with alkyl halides, alcohols,³⁴⁵ or alkenes.³⁴⁶

Friedel–Crafts alkylation is unusual among the principal aromatic substitutions in that the entering group is activating (the product is more reactive than the starting aromatic substrate), and di- and polyalkylation are frequently observed. However, the activating effect of simple alkyl groups (e.g., ethyl, isopropyl) is only ~1.5–3 times as fast as benzene for Friedel–Crafts alkylations,³⁴⁷ so it is often possible to obtain high yields of monoalkyl product.³⁴⁸ Actually, the fact that di- and polyalkyl derivatives are frequently obtained is not due to the small difference in reactivity, but to the circumstance that alkylbenzenes are preferentially soluble in the catalyst layer, where the reaction actually takes place.³⁴⁹ This factor can be removed by the use of a suitable solvent, by high temperatures, or by high-speed stirring.

³³⁷There are a few exceptions. Certain alkyl and vinylic triflates alkylate aromatic rings without a catalyst, see Gramstad, T.; Haszeldine, R.N. *J. Chem. Soc.* **1957**, 4069; Olah, G.A.; Nishimura, J. *J. Am. Chem. Soc.* **1974**, *96*, 2214; Stang, P.J.; Anderson, A.G. *J. Am. Chem. Soc.* **1978**, *100*, 1520.

It is important to note that the OH, OR, NH₂, and so on groups do not facilitate the reaction, since most Lewis acid catalysts coordinate with these basic groups. Although phenols give the usual Friedel–Crafts reactions, orienting ortho and para, the reaction is very poor for aniline derivatives. However, amines can undergo the reaction if alkenes are used as reagents and aluminum anilides as catalysts.³⁵⁰ In this method, the catalyst is prepared by treating the amine to be alkylated with $\frac{1}{3}$ equivalent of AlCl₃. A similar reaction can be performed with phenols, though here the catalyst is Al(OAr)₃.³⁵¹ Primary aromatic amines (and phenols) can be methylated regioselectively in the ortho position by an indirect method (see **11-23**). For an indirect method for regioselective ortho methylation of phenols (see p. 1247).

Naphthalene and other fused ring compounds are so reactive that they react with the catalyst, and therefore tend to give poor yields in Friedel–Crafts alkylation. Heterocyclic rings are also tend to be poor substrates for the reaction. Although some furans and thiophenes have been alkylated, polymerization is quite common, and a true alkylation of a pyridine or a quinoline has never been described.³⁵² *N*-Methylpyrrole reacted with the C=C unit of methacrolein in the presence of a chiral catalyst (a chiral Friedel–Crafts catalyst) to give the 2-alkylated pyrrole, with good enantioselectivity.³⁵³ Alkylation at C-5 of 2-trimethylsilylfuran was accomplished using the carbocation [(*p*-MeOC₆H₄)₂CH⁺ OTf] and Proton Sponge (see p. 386).³⁵⁴ Although mechanistically different, an intramolecular cyclization of an *N*-allylic pyrrole was accomplished using a rhodium catalyst with 100 atm of CO/H₂.³⁵⁵ Note that alkylation of pyridine and other nitrogen heterocycles can be accomplished by a free radical³⁵⁶ (**14-19**) and by a nucleophilic method (**13-17**). A variation generates an electrophilic species on the aromatic substrate. The reaction of isoquinoline with ClCO₂Ph and AgOTf, followed by reaction with an allylic silane, led to a 2-allylic dihydroisoquinoline.³⁵⁷

In most cases, meta-directing groups make the ring too inactive for alkylation. Nitrobenzene cannot be alkylated, and there are only a few reports of successful Friedel–Crafts alkylations when electron-withdrawing groups are present.³⁵⁸ This is not because the attacking species is not powerful enough; indeed we have

seen (p. 681) that alkyl cations are among the most powerful of electrophiles. The difficulty is caused by the fact that, with inactive substrates, degradation and polymerization of the electrophile occurs before it can attack the ring. However, if an activating and a deactivating group are both present on a ring, Friedel–Crafts alkylation can be accomplished.³⁵⁹ Aromatic nitro compounds can be methylated by a nucleophilic mechanism (13-17).

The intermediate for Friedel–Crafts alkylation is a carbocation, and rearrangement to a more stable cation can be quite facile. Therefore, rearrangement of the alkyl substrate occurs frequently and is an important synthetic limitation of Friedel–Crafts alkylation. For example, benzene treated with *n*-propyl bromide gives mostly isopropylbenzene (cumene) and much less *n*-propylbenzene. Rearrangement is usually in the order primary \rightarrow secondary \rightarrow tertiary and usually occurs by migration of the smaller group on the adjacent carbon. Therefore, in the absence of special electronic or resonance influences on the migrating group (such as phenyl), H migrates before methyl, which migrates before ethyl, and so on (see discussion of rearrangement mechanisms in Chapter 18). It is therefore not usually possible to put a primary alkyl group (other than methyl³⁶⁰ and ethyl) onto an aromatic ring by Friedel–Crafts alkylation. Because of these rearrangements, *n*-alkylbenzenes are often prepared by *acylation* (11-17), followed by reduction (19-61).

An important use of the Friedel–Crafts alkylation reaction is to effect ring closure.³⁶¹ The most common method is to heat with aluminum chloride an aromatic compound having a halogen, hydroxy, or alkene group in the proper position, as, for example, in the preparation of tetralin, 40.

Another way of effecting ring closure through Friedel–Crafts alkylation is to use a reagent containing two groups, such as 41.

These reactions are most successful for the preparation of six-membered rings,³⁶² though five- and seven-membered rings have also been closed in this

manner. For other Friedel–Crafts ring-closure reactions, see **11-15**, **11-13**, and **11-17**. An interesting variation in this reaction showed that *N*-acyl aniline derivatives, upon treatment with $\text{Et}_2\text{P}(=\text{O})\text{H}$ in water and a water soluble initiator (V-501) led to an intramolecular alkylation reaction to give an amide.³⁶³

As mentioned above, the electrophile in Friedel–Crafts alkylation is a carbocation, at least in most cases.³⁶⁴ This is in accord with the knowledge that carbocations rearrange in the direction primary \rightarrow secondary \rightarrow tertiary (see Chapter 18). In each case the cation is formed from the attacking reagent and the catalyst. For the three most important types of reagent these reactions are

There is direct evidence, from ir and nmr spectra, that the *tert*-butyl cation is quantitatively formed when *tert*-butyl chloride reacts with AlCl_3 in anhydrous liquid HCl .³⁶⁶ In the case of alkenes, Markovnikov's rule (p. 1019) is followed. Carbocation formation is particularly easy from some reagents, because of the stability of the cations. Triphenylmethyl chloride³⁶⁷ and 1-chloroadamantane³⁶⁸ alkylate activated aromatic rings (e.g., phenols, amines) with no catalyst or solvent. Ions as stable as this are less reactive than other carbocations and often attack only active substrates. The tropylium ion, for example, alkylates anisole, but not benzene.³⁶⁹ It was noted on p. 476 that relatively stable vinylic cations can be generated from certain vinylic compounds. These have been used to introduce vinylic groups into aryl substrates.³⁷⁰ Lewis acids, such as BF_3 ³⁷¹ or AlEt_3 ,³⁷² can also be used to alkylation of aromatic rings with alkene units.

There is considerable evidence that many Friedel–Crafts alkylations, especially with primary reagents, do not go through a completely free carbocation. The ion may exist as a tight ion pair with, say, AlCl_4^- as the counterion or as a complex. Among the evidence is that methylation of toluene by methyl bromide and methyl iodide gave different ortho/para/meta ratios,³⁷³ although we would expect the same ratios if the same species attacked in each case. Other evidence is that, in some cases, the reaction kinetics are third order; first order each in aromatic substrate, attacking reagent, and catalyst.³⁷⁴ In these instances a mechanism in which the carbocation is slowly formed and then rapidly attacked by the aromatic ring is ruled out since, in such a mechanism, the substrate would not appear in the rate expression. Since it is known that free carbocations, once formed, are rapidly attacked by the ring (acting as a nucleophile), there are no free carbocations here. Another possibility (with alkyl halides) is that some alkylations take place by an $\text{S}_{\text{N}}2$ mechanism (with respect to the halide), in which case no carbocations would be involved at all. However, a completely $\text{S}_{\text{N}}2$ mechanism requires inversion of configuration. Most investigations of Friedel–Crafts stereochemistry, even where an $\text{S}_{\text{N}}2$ mechanism might most be expected, have resulted in total racemization, or at best a few percent inversion. A few exceptions have been found,³⁷⁵ most notably where the reagent was optically active propylene oxide, in which case 100% inversion was reported.³⁷⁶

Rearrangement is possible even with a non-carbocation mechanism. The rearrangement could occur *before* the attack on the ring takes place. It has been shown that treatment of $\text{CH}_3^{14}\text{CH}_2\text{Br}$ with AlBr_3 in the absence of any aromatic compound gave a mixture of the starting material and $^{14}\text{CH}_3\text{CH}_2\text{Br}$.³⁷⁷ Similar results were obtained with $\text{PhCH}_2^{14}\text{CH}_2\text{Br}$, in which case the rearrangement was so fast that the rate could be measured only below -70°C .³⁷⁸ Rearrangement could also occur *after* formation of the product, since alkylation is reversible (see **11-33**).³⁷⁹

See **14-17** and **14-19** for free-radical alkylation.

A variation of this reaction involves acylation of a β -keto ester, followed by Friedel–Crafts cyclization of the ketone moiety. The product is a coumarin **43**, in what is known as the *Pechmann condensation*.³⁸⁰ Isolation of esters, such as **42**, is not

always necessary, and protonic acids can be used rather than Lewis acids. The Pechmann condensation is facilitated by the presence of hydroxyl (OH), dimethylamino (NMe₂) and alkyl groups meta to the hydroxyl of the phenol.³⁸¹ The reaction has been accomplished using microwave irradiation on graphite/Montmorillonite K10.³⁸² Pechmann condensation in an ionic liquid using ethyl acetate has also been reported.³⁸³

11-12 Hydroxyalkylation or Hydroxyalkyl-de-hydrogenation

When an aldehyde, ketone, or other carbonyl-containing substrate is treated with a protonic or Lewis acid, an oxygen-stabilized cation is generated. In the presence of an aromatic ring, Friedel–Crafts type alkylation occurs. The condensation of aromatic rings with aldehydes or ketones is called *hydroxyalkylation*.³⁸⁴ The reaction can be used to prepare alcohols,³⁸⁵ though more often the alcohol initially produced reacts with another molecule of aromatic compound (**11-11**) to give diarylation. For this the reaction is quite useful, an example being the preparation of DDT, **44**:

The diarylation reaction is especially common with phenols (the diaryl product here is called a bisphenol). The reaction is normally carried out in alkaline solution on

³⁸⁵See, for example, Casiraghi, G.; Casnati, G.; Puglia, G.; Sartori, G. *Synthesis* **1980**, 124.

the phenolate ion.³⁸⁶ Another variation involved Friedel–Crafts coupling of an aldehyde to an activated aromatic compound (an aniline derivative) to give diaryl carbinols that exhibited atropisomerism (see 146).³⁸⁷ When the reaction was done with a chiral aluminum complex, modest enantioselectivity was observed.

The hydroxymethylation of phenols with formaldehyde is called the *Lederer–Manasse reaction*. This reaction must be carefully controlled,³⁸⁸ since it is possible for the para and both ortho positions to be substituted and for each of these to be rearylated, so that a polymeric structure **45** is produced. However, such polymers, which are of the Bakelite type (phenol–formaldehyde resins, **45**), are of considerable commercial importance.

The attacking species is the carbocation,

formed from the aldehyde or ketone and the acid catalyst, except when the reaction is carried out in basic solution.

When an aromatic ring is treated with diethyl oxomalonate, $(\text{EtOOC})_2\text{C}=\text{O}$, the product is an arylmalonic acid derivative $\text{ArC}(\text{OH})(\text{COOEt})_2$, which can be converted to an arylmalonic acid, $\text{ArCH}(\text{COOEt})_2$.³⁸⁹ This is therefore a way of applying the malonic ester synthesis (**10-67**) to an aryl group (see also, **13-14**). Of course, the opposite mechanism applies here: The aryl species is the nucleophile.

Two methods, both involving boron-containing reagents, have been devised for the regioselective ortho hydroxymethylation of phenols or aromatic amines.³⁹⁰

11-13 Cyclodehydration of Carbonyl-Containing Compounds

As described in the previous section (11-12), the reaction of carbonyl-containing functional groups with protonic or Lewis acids lead to oxygen-stabilized carbocations. When generated in the presence of an aromatic ring, Friedel–Crafts alkylation occurs to give an alcohol or an alkene, if dehydration occurs under the reaction conditions. When an aromatic compound contains an aldehyde or ketone function in a position suitable for closing a suitably sized ring, treatment with acid results in cyclodehydration. The reaction is a special case of 11-12, but in this case dehydration almost always takes place to give a double bond conjugated with the aromatic ring.³⁹¹ The method is very general and is widely used to close both carbocyclic and heterocyclic rings.³⁹² Polyphosphoric acid is a common reagent, but other acids have also been used. In a variation known as the *Bradsher reaction*,³⁹³ diarylmethanes containing a carbonyl group in the ortho position can be cyclized to anthracene derivatives, **46**. In this case, 1,4-dehydration takes place, at least formally.

An intramolecular cyclization of an aryl ether to the carbonyl of a pendant aryl ketone, on clay with microwave irradiation, led to a benzofuran via Friedel–Crafts cyclization and elimination of water.³⁹⁴

The carbonyl unit involved in the cyclization process is not restricted to aldehydes and ketones. The carbonyl of acid derivatives, such as amides can also be utilized. One of the more important cyclodehydration reactions is applied to the formation of heterocyclic systems via cyclization of β -aryl amides, in what is called the *Bischler–Napieralski reaction*.³⁹⁵ In this reaction amides of the type **47** are

³⁹¹For examples where the hydroxy compound was the principal product (with R = CF₃), see Fung, S.; Abraham, N.A.; Bellini, F.; Sestanj, K. *Can. J. Chem.* **1983**, *61*, 368; Bonnet-Delpon, D.; Charpentier-Morize, M.; Jacquot, R. *J. Org. Chem.* **1988**, *53*, 759.

cyclized with phosphorous oxychloride or other reagents, including polyphosphoric acid, sulfuric acid or phosphorus pentoxide, to give a dihydroisoquinoline, **48**. The Bischler–Napieralski reaction has been done in ionic liquids using POCl_3 .³⁹⁶ The reaction has also been done using solid-phase (see p. 416) techniques.³⁹⁷

If the starting compound contains a hydroxyl group in the α position, an additional dehydration takes place and the product is an isoquinoline.³⁹⁸ Higher yields can be obtained if the amide is treated with PCl_5 to give an imino chloride $\text{ArCH}_2\text{CH}_2\text{N}=\text{CR}-\text{Cl}$, which is isolated and then cyclized by heating.³⁹⁹ In this latter case, a nitrilium ion $\text{ArCH}_2\text{CH}_2^{\oplus}\text{N}\equiv\text{CR}$ is an intermediate.

Another useful variation is the *Pictet–Spengler isoquinoline synthesis*, also known as the *Pictet–Spengler reaction*.⁴⁰⁰ The reactive intermediate is an iminium ion **49** rather than an oxygen-stabilized cation, but attack at the electrophilic carbon of the $\text{C}=\text{N}$ unit (see **16-31**) leads to an isoquinoline derivative. When a β -arylamine reacts with an aldehyde, the product is an iminium salt, which cyclizes with an aromatic ring to complete the reaction and generate a tetrahydroisoquinoline.⁴⁰¹ A variety of aldehydes can be used, and substitution on the aromatic ring leads to many derivatives. When the reaction is done in the presence of a chiral thiourea catalyst, good enantioselectivity was observed.⁴⁰²

Another variation in this basic procedure leads to tetrahydroisoquinolines. When phenethylamine was treated with *N*-hydroxymethylbenzotriazole and then AlCl_3 in chloroform, cyclization occurred, and reduction with sodium borohydride gave the 1,2,3,4-tetrahydro-*N*-methylisoquinoline.⁴⁰³

³⁹⁶The reaction was done in bmim PF_6 , 1-butyl-3-methylimidazolium hexafluorophosphate: Judeh, Z.M.A.; Ching, C.B.; Bu, J.; McCluskey, A. *Tetrahedron Lett.* **2002**, 43, 5089.

11-14 Haloalkylation or Haloalkyl-de-hydrogenation

When certain aromatic compounds are treated with formaldehyde and HCl, the CH_2Cl group is introduced into the ring in a reaction called *chloromethylation*. The reaction has also been carried out with other aldehydes and with HBr and HI. The more general term *haloalkylation* covers these cases.⁴⁰⁴ The reaction is successful for benzene, and alkyl-, alkoxy-, and halobenzenes. It is greatly hindered by meta-directing groups, which reduce yields or completely prevent the reactions. Amines and phenols are too reactive and usually give polymers unless deactivating groups are also present, but phenolic ethers and esters successfully undergo the reaction. Compounds of lesser reactivity can often be chloromethylated with chloromethyl methyl ether (ClCH_2OMe), or methoxyacetyl chloride $\text{MeOCH}_2\text{COCl}$.⁴⁰⁵ Zinc chloride is the most common catalyst, but other Friedel–Crafts catalysts are also employed. As with reaction 11-12 and for the same reason, an important side product is the diaryl compound Ar_2CH_2 (from formaldehyde).

Apparently, the initial step involves reaction of the aromatic compound with the aldehyde to form the hydroxyalkyl compound, exactly as in 11-12, and then the HCl converts this to the chloroalkyl compound.⁴⁰⁶ The acceleration of the reaction by ZnCl_2 has been attributed⁴⁰⁷ to the raising of the acidity of the medium, causing an increase in the concentration of HOCH_2^+ ions.

OS III, 195, 197, 468, 557; IV, 980.

11-15 Friedel–Crafts Arylation: The Scholl Reaction

De-hydrogen-coupling

The coupling of two aromatic molecules by treatment with a Lewis acid and a proton acid is called the *Scholl reaction*.⁴⁰⁸ Yields are low and the synthesis is seldom useful. High temperatures and strong-acid catalysts are required, and the reaction fails for substrates that are destroyed by these conditions. Because the reaction

⁴⁰⁷Lyushin, M.M.; Mekhtiev, S.D.; Guseinova, S.N. *J. Org. Chem. USSR* **1970**, *6*, 1445.

⁴⁰⁸For reviews, see Kovacic, P.; Jones, M.B. *Chem. Rev.* **1987**, *87*, 357; Balaban, A.T.; Nenitzescu, C.D., in Olah, G.A. *Friedel–Crafts and Related Reactions*, Vol. 2, Wiley, NY, **1964**, pp. 979–1047.

becomes important with large fused-ring systems, ordinary Friedel–Crafts reactions (**11-11**) on these systems are rare. For example, naphthalene gives binaphthyl under Friedel–Crafts conditions. Yields can be increased by the addition of a salt, such as CuCl_2 or FeCl_3 , which acts as an oxidant.⁴⁰⁹ Rhodium catalysts have also been used.⁴¹⁰

Intramolecular Scholl reactions, such as formation of **50** from triphenylmethane,

are much more successful than the intermolecular reaction. The mechanism is not clear, but it may involve attack by a proton to give an arenium ion of the type **12** (p. 662), which would be the electrophile that attacks the other ring.⁴¹¹ Sometimes arylations have been accomplished by treating aromatic substrates with particularly active aryl halides, especially fluorides. For free-radical arylations, see reactions **12-15**, **13-26**, **13-27**, **13-10**, **14-17**, and **14-18**.

OS IV, 482; X, 359. Also see, OS V, 102, 952.

11-16 Arylation of Aromatic Compounds By Metalated Aryls

Many metalated aryl compounds are known to couple with aromatic compounds. Aniline derivatives react with $\text{ArPb}(\text{OAc})_3$, for example, to give the 2-arylaniline.⁴¹² Phenolic anions also react to form biaryls, with modest enantioselectivity in the presence of brucine.⁴¹³

Phenylboronates $[\text{ArB}(\text{OR})_2]$ react with electron-deficient aromatic compounds, such as acetophenone, to give the biaryl.⁴¹⁴ Arylboronates also react with π -allyl palladium complexes to form the alkylated aromatic compound.⁴¹⁵

11-17 Friedel–Crafts Acylation

Acylation or Acyl-de-hydrogenation

The most important method for the preparation of aryl ketones is known as *Friedel–Crafts acylation*.⁴¹⁶ The reaction is of wide scope. Reagents other than acyl halides can be used,⁴¹⁷ including carboxylic acids,⁴¹⁸ anhydrides, and ketenes. Oxalyl chloride has been used to give diaryl 1,2-diketones.⁴¹⁹ Carboxylic esters usually give alkylation as the predominant product (see **11-11**).⁴²⁰ *N*-Carbamoyl β -lactams reacted with naphthalene in the presence of trifluoromethanesulfonic acid to give the keto-amide.⁴²¹

The alkyl group (R in RCOCl) may be aryl as well as alkyl. The major disadvantages of Friedel–Crafts alkylation, polyalkylation, and rearrangement of the intermediate carbocation, are not a problem in Friedel–Crafts acylation. Rearrangement of the alkyl group (R in RCOCl) is never found because the intermediate is an acylium ion (an acyl cation, $\text{RC}\equiv\text{O}^+$, see below). Because the RCO group is deactivating, the reaction stops cleanly after one group is introduced. All four acyl halides can be used, though chlorides are most commonly employed. The order of activity is usually, but not always, $\text{I} > \text{Br} > \text{Cl} > \text{F}$.⁴²² Catalysts are Lewis acids,⁴²³ similar to those in reaction **11-11**, but in acylation a little > than 1 equivalent of catalyst is required per mole of reagent, because the first mole coordinates

with the oxygen of the reagent [as in $R(Cl)C=O^+ \text{ } ^-AlCl_3$].⁴²⁴ A reusable catalyst $[Ln(OTf)_3-LiClO_4]$ has been developed as well.⁴²⁵ HY-Zeolite has also been used to facilitate the reaction with acetic anhydride.⁴²⁶ A platinum catalyst was used with acetic anhydride,⁴²⁷ $TiCl_4$ with acetyl chloride⁴²⁸ or acetyl chloride and zinc powder with microwave irradiation.⁴²⁹ Friedel–Crafts acylation using a carboxylic acid with a catalyst called Envirocat-EPIC (an acid-treated clay-based material) was reported.⁴³⁰ Friedel–Crafts acylation was reported in an ionic liquid.⁴³¹ An interesting acylation reaction was reported that coupled trichlorophenylmethane to benzene, giving benzophenone in the presence of the ionic liquid $AlCl_3-n-BPC$.⁴³² Acylation has been accomplished in carbon disulfide.⁴³³

Proton acids can be used as catalysts when the reagent is a carboxylic acid. The mixed carboxylic sulfonic anhydrides $RCOOSO_2CF_3$ are extremely reactive acylating agents and can smoothly acylate benzene without a catalyst.⁴³⁴ With active substrates (e.g., aryl ethers, fused-ring systems, thiophenes), Friedel–Crafts acylation can be carried out with very small amounts of catalyst, often just a trace, or even sometimes with no catalyst at all.

The reaction is quite successful for many types of substrate, including fused ring systems, which give poor results in **11-11**. Compounds containing ortho–para-directing groups, including alkyl, hydroxy, alkoxy, halogen, and acetamido groups, are easily acylated and give mainly or exclusively the para products, because of the relatively large size of the acyl group. However, aromatic amines give poor results. With amines and phenols there may be competition for *N*- or *O*-acylation; however, *O*-acylated phenols can be converted to *C*-acylated phenols by the Fries rearrangement (**11-27**). Friedel–Crafts acylation is usually prevented by meta-directing groups. Indeed, nitrobenzene is often used as a solvent for the reaction. Many heterocyclic systems, including furans, thiophenes, pyrans, and pyrroles⁴³⁵

⁴²⁴The crystal structures of several of these complexes have been reported: Rasmussen, S.E.; Broch, N.C. *Acta Chem. Scand.* **1966**, *20*, 1351; Chevrier, B.; Le Carpentier, J.; Weiss, R. *J. Am. Chem. Soc.* **1972**, *94*, 5718. For a review of these complexes, see Chevrier, B.; Weiss, R. *Angew. Chem. Int. Ed.* **1974**, *13*, 1.

but not pyridines or quinolines, can be acylated in good yield. Initial reaction of indole with Et_2AlCl ⁴³⁶ or SnCl_4 ,⁴³⁷ followed by acetyl chloride leads to 3-acetylindole. By comparison, the reaction of *N*-acetylindole with acetic anhydride and AlCl_3 gave *N*,6-diacetylindole.⁴³⁸ Acetylation at C-3 was also accomplished with acetyl chloride in the ionic liquid emimcl- AlCl_3 .⁴³⁹ Gore, in Ref. 417 (pp. 36–100; with tables, pp. 105–321), presents an extensive summary of the substrates to which this reaction has been applied. Pyridines and quinolines can be also be acylated by a free-radical mechanism (reaction 14-19).

When a mixed-anhydride $\text{RCOOCOR}'$ is the reagent, two products are possible: ArCOR and ArCOR' . Which product predominates depends on two factors. If R contains electron-withdrawing groups, then ArCOR' is chiefly formed, but if this factor is approximately constant in R and R', the ketone with the larger R group predominantly forms.⁴⁴⁰ This means that *formylations* of the ring do not occur with mixed anhydrides of formic acid HCOOCOR .

An important use of the Friedel–Crafts acylation is to effect ring closure.⁴⁴¹ This can be done if an acyl halide, anhydride, or carboxylic acid⁴⁴² group is in the proper position. An example is the conversion of **51** to **52**.

The reaction is used mostly to close six-membered rings, but has also been done for five- and seven-membered rings, which close less readily. Even larger rings can be closed by high-dilution techniques.⁴⁴³ Tricyclic and larger systems are often made by using substrates containing one of the acyl groups on a ring. Many fused-ring systems are made in this manner. If the bridging group is CO, the product is a quinone.⁴⁴⁴ One of the most common catalysts for intramolecular Friedel–Crafts

⁴⁴⁴For discussions, see Naruta, Y.; Maruyama, K., in Patai, S.; Rappoport, Z. *The Chemistry of the Quinonoid Compounds*, Vol. 2, pt. 1, Wiley, NY, **1988**, pp. 325–332; Thomson, R.H., in Patai, S. *The Chemistry of the Quinonoid Compounds*, Vol. 1, pt. 1, Wiley, NY, **1974**; pp. 136–139.

acylation is polyphosphoric acid⁴⁴⁵ (because of its high potency), but AlCl_3 , H_2SO_4 , and other Lewis and proton acids are also used, though acylations with acyl halides are not generally catalyzed by proton acids.

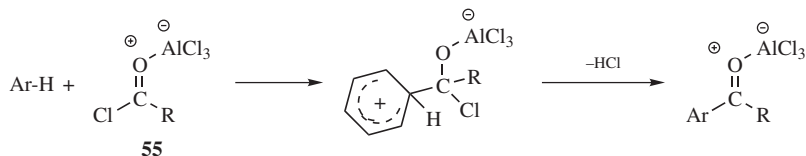

Friedel–Crafts acylation can be carried out with cyclic anhydrides,⁴⁴⁶ in which case the product contains a carboxyl group in the side chain (**53**). When succinic anhydride is used, the product is $\text{ArCOCH}_2\text{CH}_2\text{COOH}$. This can be reduced (**19-61**) to $\text{ArCH}_2\text{CH}_2\text{CH}_2\text{COOH}$, which can then be cyclized by an internal Friedel–Crafts acylation to give **54**. The total process is called the *Haworth reaction*.⁴⁴⁷

The mechanism of Friedel–Crafts acylation is not completely understood,⁴⁴⁸ but at least two mechanisms probably operate, depending on conditions.⁴⁴⁹ In most cases the attacking species is the acyl cation, either free or as an ion pair, formed by⁴⁵⁰

If R is tertiary, RCO^+ may lose CO to give R^+ , so that the alkyl arene ArR is often a side product or even the main product. This kind of cleavage is much more likely with relatively unreactive substrates, where the acylium ion has time to break down. For example, pivaloyl chloride Me_3CCOCl gives the normal acyl product with anisole, but the alkyl product Me_3CPh with benzene. In the other mechanism, an acyl cation is not involved, but the 1:1 complex (**55**) attacks directly.⁴⁵¹

⁴⁵⁰After 2 min, exchange between PhCOCl and $\text{Al}(^{36}\text{Cl})_3$ is complete: Oulevey, G.; Susz, P.B. *Helv. Chim. Acta* **1964**, *47*, 1828.

⁴⁵¹For example, see Corriu, R.; Dore, M.; Thomassin, R. *Tetrahedron* **1971**, *27*, 5601, 5819; Tan, L.K.; Brownstein, S. *J. Org. Chem.* **1983**, *48*, 302.

Free-ion attack is more likely for sterically hindered R.⁴⁵² The ion CH_3CO^+ has been detected (by IR spectroscopy) in the liquid complex between acetyl chloride and aluminum chloride, and in polar solvents, such as nitrobenzene; but in nonpolar solvents, such as chloroform, only the complex and not the free ion is present.⁴⁵³ In any event, 1 equivalent of catalyst certainly remains complexed to the product at the end of the reaction. When the reaction is performed with $\text{RCO}^+\text{SbF}_6^-$, no catalyst is required and the free ion⁴⁵⁴ (or ion pair) is undoubtedly the attacking entity.⁴⁵⁵ The use of LiClO_4 on the metal triflate-catalyzed Friedel–Crafts acylation of methoxynaphthalene derivatives has been examined, and the presence of the lithium salt leads to acylation in the ring containing the methoxy unit, whereas reaction occurs in the other ring in the absence of lithium salts.⁴⁵⁶ Note that lithium perchlorate forms a complex with acetic anhydride, which can be used for the Friedel–Crafts acylation of activated aromatic compounds.⁴⁵⁷

Reaction 11-18 is a direct formylation of the ring.⁴⁵⁸ Reaction 11-17 has not been used for formylation, since neither formic anhydride nor formyl chloride is stable at ordinary temperatures. Formyl chloride has been shown to be stable in chloroform solution for 1 h at -60°C ,⁴⁵⁹ but it is not useful for formylating aromatic rings under these conditions. Formic anhydride has been prepared in solution, but has not been isolated.⁴⁶⁰ Mixed anhydrides of formic and other acids are known⁴⁶¹ and can be used to formylate amines (see 16-73) and alcohols, but no formylation takes place when they are applied to aromatic rings. See 13-17 for a nucleophilic method for the formylation of aromatic rings.

A related reaction involves a biaryl, where one ring is a phenol. Treatment with BCl_3 and an AlCl_3 catalyst, followed by reaction with CO and $\text{Pd}(\text{OAc})_2$, led to

carbonylation and acylation to give the corresponding lactone.⁴⁶² Carbonylation of aromatic compounds can lead to aryl ketones. Heating an aromatic compound with Ru(CO)₁₂, ethylene and 20 atm of CO gave the corresponding aryl ethyl ketone.⁴⁶³

11-18 Formylation

Formylation or Formyl-de-hydrogenation

The reaction with disubstituted formamides R₂N-CHO and phosphorus oxychloride, called the *Vilsmeier* or the *Vilsmeier-Haack reaction*,⁴⁶⁴ is the most common method for the formylation of aromatic rings.⁴⁶⁵ However, it is applicable only to active substrates, such as amines and phenols. An intramolecular version is also known.⁴⁶⁶ Aromatic hydrocarbons and heterocycles can also be formylated, but only if they are much more active than benzene (e.g., azulenes, ferrocenes). Although *N*-phenyl-*N*-methylformamide is a common reagent, other arylalkyl amides and dialkyl amides are also used.⁴⁶⁷ Phosgene (COCl₂) has been used in place of POCl₃. The reaction has also been carried out with other amides to give ketones (actually an example of **11-17**), but not often. The attacking species⁴⁶⁸ is **56**,⁴⁶⁹ and the mechanism is probably that shown to give **57**, which is unstable and easily hydrolyzes to the product. Either formation of **56** or the reaction of **56** with the substrate can be rate determining, depending on the reactivity of the substrate.⁴⁷⁰

When $(\text{CF}_3\text{SO}_2)_2\text{O}$ was used instead of POCl_3 , the reaction was extended to some less-active compounds, including naphthalene and phenanthrene.⁴⁷¹

In a related reaction, paraformaldehyde can be used, with $\text{MgCl}_2\text{-NEt}_3$, to convert phenol to phenol 2-carboxaldehyde.⁴⁷² Another variation treated acetanilide with $\text{POCl}_3\text{-DMF}$ and generated 2-chloroquinoline-3-carboxaldehyde.⁴⁷³ Used in conjunction with conjugated hydroxylamines, a tandem Vilsmeier–Beckman reaction (see **18-17** for the Beckman rearrangement) leads to pyridines (2-chloro-3-carboxaldehyde).⁴⁷⁴ A chain-extension variation has been reported in which an aryl alkyl ketone is treated with POCl_3/DMF on silica with microwave irradiation to give a conjugated aldehyde, $\text{ArC(=O)R} \rightarrow \text{ArC(Cl)=CHCHO}$.⁴⁷⁵

OS **I**, 217; **III**, 98, **IV**, 331, 539, 831, 915.

Formylation with Zn(CN)_2 and HCl is called the *Gatterman reaction*.⁴⁷⁶ It can be applied to alkylbenzenes, phenols and their ethers, and many heterocyclic compounds. However, it cannot be applied to aromatic amines. In the original version of this reaction the substrate was treated with HCN , HCl , and ZnCl_2 , but the use of Zn(CN)_2 and HCl (HCN and ZnCl_2 are generated *in situ*) makes the reaction more convenient to carry out and yields are not diminished. The mechanism of the Gatterman reaction has not been investigated very much, but it is known that an initially formed but not isolated nitrogen-containing product is hydrolyzed to aldehyde. This product is presumed to be $\text{ArCH=NH}_2^+ \text{Cl}^-$, as shown. When benzene was treated with NaCN under superacid conditions ($\text{F}_3\text{CSO}_2\text{OH-SbF}_5$, see p. 236), a good yield of product was obtained, leading to the conclusion that the electrophile in this case was $^+\text{C(H)=N}^+\text{H}_2$.⁴⁷⁷ The Gatterman reaction may be regarded as a special case of **11-24**.

Another method, formylation with CO and HCl in the presence of AlCl_3 and CuCl ⁴⁷⁸ (the *Gatterman–Koch reaction*), is limited to benzene and alkylbenzenes.⁴⁷⁹

OS II, 583; III, 549.

In the *Reimer–Tiemann reaction*, aromatic rings are formylated by reaction with chloroform and hydroxide ion.⁴⁸⁰ The method is useful only for phenols and certain heterocyclic compounds such as pyrroles and indoles. Unlike the previous formylation methods (**11-18**), this one is conducted in basic solution. Yields are generally low, seldom rising above 50%.⁴⁸¹ The incoming group is directed ortho, unless both ortho positions are filled, in which case the attack is para.⁴⁸² Certain substrates have been shown to give abnormal products instead of or in addition to the normal ones. For example, **58** and **60** gave, respectively, **59** and **61** as well as the normal aldehyde products. From the nature of the reagents and

from the kind of abnormal products obtained, it is clear that the reactive entity in this reaction is dichlorocarbene CCl₂.⁴⁸³ This is known to be produced by treatment of chloroform with bases (p. 521); it is an electrophilic reagent and is known to give ring expansion of aromatic rings (see **15-64**), accounting for products like **58**. The mechanism of the normal reaction is thus something like this.⁴⁸⁴

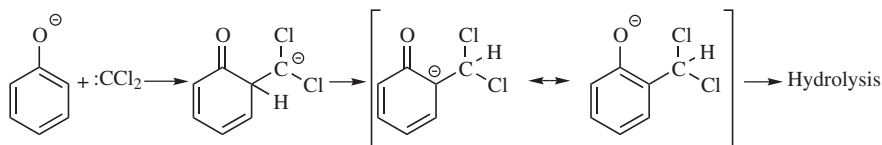

⁴⁸⁰For a review, see Wynberg, H.; Meijer, E.W. *Org. React.* **1982**, 28, 1.

⁴⁸²Increased para selectivity has been achieved by the use of polyethylene glycol: Neumann, R.; Sasson, Y. *Synthesis* **1986**, 569.

⁴⁸³For a review of carbene methods for introducing formyl and acyl groups into organic molecules see Kulinkovich, O.G. *Russ. Chem. Rev.* **1989**, 58, 711.

⁴⁸⁴Robinson, E.A. *J. Chem. Soc.* **1961**, 1663; Hine, J.; van der Veen, J.M. *J. Am. Chem. Soc.* **1959**, 81, 6446. See also, Langlois, B.R. *Tetrahedron Lett.* **1991**, 32, 3691.

The formation of **61** in the case of **60** can be explained by attack of some of the CCl_2 ipso to the CH_3 group. Since this position does not contain a hydrogen, normal proton loss cannot take place and the reaction ends when the CCl_2^- moiety acquires a proton.

A method closely related to the Reimer–Tiemann reaction is the *Duff reaction*, in which hexamethylenetetramine $(\text{CH}_2)_6\text{N}_4$ is used instead of chloroform. This reaction can be applied only to phenols and amines; ortho substitution is generally observed and yields are low. A mechanism⁴⁸⁵ has been proposed that involves initial aminoalkylation (**11-22**) to give ArCH_2NH_2 , followed by dehydrogenation to $\text{ArCH}=\text{NH}$ and hydrolysis of this to the aldehyde product. When $(\text{CH}_2)_6\text{N}_4$ is used in conjunction with F_3CCOOH , the reaction can be applied to simple alkylbenzenes; yields are much higher and a high degree of regioselectively para substitution is found.⁴⁸⁶ In this case too an imine seems to be an intermediate.

OS III, 463; IV, 866

Besides **11-18**, several other formylation methods are known.⁴⁸⁷ In one of these, dichloromethyl methyl ether formylates aromatic rings with Friedel–Crafts catalysts.⁴⁸⁸ The ArCHClOMe compound is probably an intermediate. Orthoformates have also been used.⁴⁸⁹ In another method, aromatic rings are formylated with formyl fluoride HCOF and BF_3 .⁴⁹⁰ Unlike formyl chloride, formyl fluoride is stable enough for this purpose. This reaction was successful for benzene, alkylbenzenes, PhCl , PhBr , and naphthalene. Phenols can be regioselectively formylated in the ortho position in high yields by treatment with 2 equivalents of paraformaldehyde in aprotic solvents in the presence of SnCl_4 and a tertiary amine.⁴⁹¹ Phenols have also been formylated indirectly by conversion to the aryllithium reagent followed by treatment with *N*-formyl piperidine.⁴⁹² See also the indirect method mentioned at **11-23**.

Reactions **11-19** and **11-20** are direct carboxylations⁴⁹³ of aromatic rings.⁴⁹⁴

11-19 Carboxylation With Carbonyl Halides

Carboxylation or Carboxy-de-hydrogenation

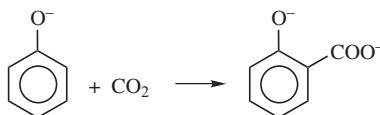

Phosgene, in the presence of Friedel–Crafts catalysts, can carboxylate the ring. This process is analogous to **11-17**, but the ArCOCl initially produced hydrolyzes to the carboxylic acid. However, in most cases the reaction does not take this course, but instead the ArCOCl attacks another ring to give a ketone ArCOAr. A number of other reagents have been used to get around this difficulty, among them oxalyl chloride, urea hydrochloride, chloral Cl_3CCHO ,⁴⁹⁵ carbamoyl chloride H_2NCOCl , and *N,N*-diethylcarbamoyl chloride.⁴⁹⁶ With carbamoyl chloride the reaction is called the *Gatterman amide synthesis* and the product is an amide. Among compounds carboxylated by one or another of these reagents are benzene, alkylbenzenes, and fused ring systems.⁴⁹⁷

Although mechanistically different, other methods are available to convert aromatic compounds to aromatic carboxylic acids. The palladium-catalyzed reaction of aromatic compounds and formic acid leads to benzoic acid derivatives.⁴⁹⁸ Diphenyliodonium tetrafluoroborate, $\text{Ph}_2\text{I}^+\text{BF}_4^-$ reacts with CO and In in DMF, with a palladium catalyst, to give benzophenone.⁴⁹⁹

Sodium phenoxides can be carboxylated, mostly in the ortho position, by carbon dioxide (the *Kolbe–Schmitt reaction*). The mechanism is not clearly understood, but apparently some kind of a complex is formed between the reactants,⁵⁰⁰ making the carbon of the CO₂ more positive and putting it in a good

position to attack the ring. Potassium phenoxide, which is less likely to form such a complex,⁵⁰¹ is chiefly attacked in the para position.⁵⁰² Carbon tetrachloride can be used instead of CO₂ under Reimer–Tiemann (**11-18**) conditions.

Sodium or potassium phenoxide can be carboxylated regioselectively in the para position in high yield by treatment with sodium or potassium carbonate and carbon monoxide.⁵⁰³ ¹⁴C Labeling showed that it is the carbonate carbon that appears in the *p*-hydroxybenzoic acid product.⁵⁰⁴ The CO is converted to sodium or potassium formate. Carbon monoxide has also been used to carboxylate aromatic rings with palladium compounds as catalysts.⁵⁰⁵ In addition, a palladium-catalyzed reaction has been used directly to prepare acyl fluorides ArH → ArCOF.⁵⁰⁶

An enzymatic carboxylation was reported, in supercritical CO₂ (see p. \$\$\$), in which exposure of pyrrole to *Bacillus megaterium* PYR2910 and KHCO₃ gave the potassium salt of pyrrole-2-carboxylic acid.⁵⁰⁷

OS II, 557.

11-21 Amidation

N-Alkylcarbamoyl-de-hydrogenation

⁵⁰⁰Hales J.L.; Jones, J.I.; Lindsey, A.S. *J. Chem. Soc.* **1954**, 3145.

⁵⁰¹There is evidence that, in the complex formed from potassium salts, the bonding is between the aromatic compound and the carbon atom of CO₂; Hirao, I.; Kito, T. *Bull. Chem. Soc. Jpn.* **1973**, *46*, 3470.

⁵⁰²Actually, the reaction seems to be more complicated than this. At least part of the potassium *p*-hydroxybenzoate that forms comes from a rearrangement of initially formed potassium salicylate. Sodium salicylate does not rearrange. See Shine, H.J. *Aromatic Rearrangements*, Elsevier, NY, **1967**, pp. 344–348. See also, Ota, K. *Bull. Chem. Soc. Jpn.* **1974**, *47*, 2343.

N-Substituted amides can be prepared by direct attack of isocyanates on aromatic rings.⁵⁰⁸ The R group may be alkyl or aryl, but if the latter, dimers and trimers are also obtained. Isothiocyanates similarly give thioamides.⁵⁰⁹ The reaction has been carried out intramolecularly both with aralkyl isothiocyanates and acyl isothiocyanates.⁵¹⁰ In the latter case, the product is easily hydrolyzable to a dicarboxylic acid; this is a way

of putting a carboxyl group on a ring ortho to one already there (**62** is prepared by treatment of the acyl halide with lead thiocyanate). The reaction gives better yields with substrates of the type $\text{ArCH}_2\text{CONCS}$, where six-membered rings are formed.

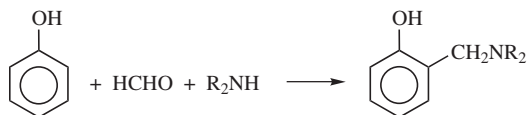

There are interesting transition metal-catalyzed-reactions that lead to aryl amides. The use of POCl_3 and DMF, with a palladium catalyst, converts aryl iodides to benzamides.⁵¹¹ A palladium-catalyzed reaction of aryl halides and formamide leads to benzamide derivatives.⁵¹² Carbonylation is another method that generates amides. When an aryl iodide was treated with a secondary amine and $\text{Mo}(\text{CO})_6$, in the presence of 3 equivalents of DBU, 10% $\text{Pd}(\text{OAc})_2$, with microwave irradiation at 100°C , the corresponding benzamide was obtained.⁵¹³

OS V, 1051; VI, 465.

Reactions **11-12–11-23** involve the introduction of a CH_2Z group, where Z is halogen, hydroxyl, amino, or alkylthio. They are all Friedel–Crafts reactions of aldehydes and ketones and, with respect to the carbonyl compound, additions to the $\text{C}=\text{O}$ double bond. They follow mechanisms discussed in Chapter 16.

11-22 Aminoalkylation and Amidoalkylation

Dialkylaminoalkylation or Dialkylamino-de-hydrogenation

Phenols, secondary and tertiary aromatic amines,⁵¹⁴ pyrroles, and indoles can be aminomethylated by treatment with formaldehyde and a secondary amine. Other aldehydes have sometimes been employed. Aminoalkylation is a special case of the Mannich reaction (16-19). When phenols and other activated aromatic compounds are treated with *N*-hydroxymethylchloroacetamide, *amidomethylation* takes place⁵¹⁵ to

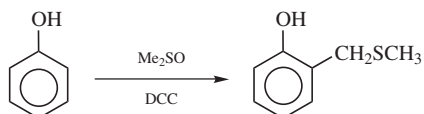

give **63**, which is often hydrolyzed *in situ* to the aminoalkylated product. Other *N*-hydroxyalkyl and *N*-chlorinated compounds have also been used.³⁷⁴

11-23 Thioalkylation

Alkylthioalkylation or Alkylthioalkyl-de-hydrogenation

A methylthiomethyl group can be inserted into the ortho position of phenols by heating with dimethyl sulfoxide and dicyclohexylcarbodiimide (DCC).⁵¹⁶ Other reagents can be used instead of DCC, among them SOCl_2 ,⁵¹⁷ and acetic anhydride.⁵¹⁸ Alternatively, the phenol can be treated with dimethyl sulfide and *N*-chlorosuccinimide, followed by triethylamine.⁵¹⁹ The reaction can be applied to amines (to give *o*- $\text{NH}_2\text{C}_6\text{H}_4\text{CH}_2\text{SMe}$) by treatment with *t*-BuOCl, Me_2S , and NaOMe in CH_2Cl_2 .⁵²⁰ Aromatic hydrocarbons have been thioalkylated with ethyl α -(chloromethylthio)-acetate $\text{ClCH}_2\text{SCH}_2\text{COOEt}$ (to give $\text{ArCH}_2\text{SCH}_2\text{CO-OEt}$)⁵²¹ and with methyl methylsulfynylmethyl sulfide $\text{MeSCH}_2\text{SOMe}$ or methylthiomethyl *p*-tolyl sulfone $\text{MeSCH}_2\text{SO}_2\text{C}_6\text{H}_4\text{Me}$ (to give ArCH_2SMe),⁵²² in each case with a Lewis acid catalyst.

11-24 Acylation with Nitriles: The Hoesch Reaction

Acylation or Acyl-de-hydrogenation

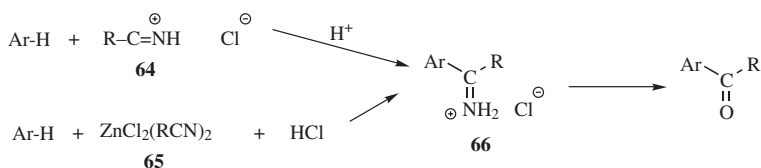

Friedel–Crafts acylation with nitriles and HCl is called the *Hoesch* or the *Houben–Hoesch reaction*.⁵²³ In most cases, a Lewis acid is necessary; zinc chloride is the most common. The reaction is generally useful only with phenols, phenolic ethers, and some reactive heterocyclic compounds such as pyrrole, but it can be extended to aromatic amines by the use of BCl_3 .⁵²⁴ Acylation in the case of aniline derivatives is regioselectively ortho. Monohydric phenols, however, generally do not give ketones⁵²⁵ but are attacked at the oxygen to

produce imino esters. Many nitriles have been used. Even aryl nitriles give good yields if they are first treated with HCl and ZnCl_2 and then the substrate added at 0°C .⁵²⁶ In fact, this procedure increases yields with any nitrile. If thiocyanates RSCN are used, thiol esters ArCOSR can be obtained. The Gatterman reaction (11-18) is a special case of the Hoesch synthesis.

The reaction mechanism is complex and not completely settled.⁵²⁷ The first stage consists of an attack on the substrate by a species containing the nitrile and HCl (and the Lewis acid, if present) to give an imine salt (66). Among the possible attacking species are 64 and 65. In the second stage, the salts are hydrolyzed to the products, first the iminium salt, and then the ketone. Ketones can also be obtained by treating phenols or phenolic ethers with a nitrile in the presence of $\text{F}_3\text{CSO}_2\text{OH}$.⁵²⁸ The mechanism in this case is different.

11-25 Cyanation or Cyano-de-hydrogenation

Aromatic hydrocarbons (including benzene), phenols, and phenolic ethers can be cyanated with trichloroacetonitrile, BrCN, or mercury fulminate $\text{Hg}(\text{ONC})_2$.⁵²⁹ In the case of Cl_3CCN , the actual attacking entity is probably $\text{Cl}_3\text{C}-\text{C}=\text{NH}$, formed by addition of a proton to the cyano nitrogen. Secondary aromatic amines ArNHR , as well as phenols, can be cyanated in the ortho position with Cl_3CCN and BCl_3 .⁵³⁰

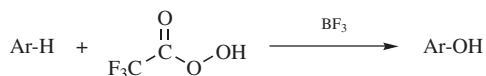

It is noted that aryl triflates are converted to the aryl nitrile by treatment with $\text{Zn}(\text{CN})_2$ and a palladium catalyst.⁵³¹

OS III, 293.

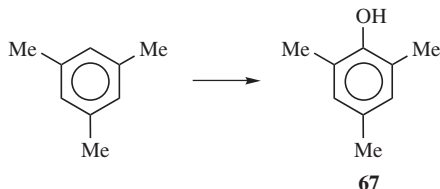

F. Oxygen Electrophiles

Oxygen electrophiles are very uncommon, since oxygen does not bear a positive charge very well. However, there is one reaction that can be mentioned.

11-26 Hydroxylation or Hydroxy-de-hydrogenation

There have been only a few reports of direct hydroxylation⁵³² by an electrophilic process (see, however, 14-5).⁵³³ In general, poor results are obtained, partly because the introduction of an OH group activates the ring to further attack. Quinone formation is common. However, alkyl-substituted benzenes, such as mesitylene or durene can be hydroxylated in good yield with trifluoroperacetic acid and boron trifluoride.⁵³⁴ In the case of mesitylene, the product (**67**) is not subject to further attack.

In a related procedure, even benzene and substituted benzenes (e.g., PhMe, PhCl, xylenes) can be converted to phenols in good yields with sodium perborate– F_3CSO_2OH .⁵³⁵ Aromatic amines, *N*-acyl amines, and phenols were hydroxylated with H_2O_2 in SbF_5-HF .⁵³⁶ Pyridine and quinoline were converted to their 2-acetoxy derivatives in high yields with acetyl hypofluorite $AcOF$ at $-75^\circ C$.⁵³⁷

Another hydroxylation reaction is the *Elbs reaction*.⁵³⁸ In this method phenols can be oxidized to *p*-diphenols with $K_2S_2O_8$ in alkaline solution.⁵³⁹ Primary, secondary, or tertiary aromatic amines give predominant or exclusive ortho substitution unless both ortho positions are blocked, in which case para substitution is found. The reaction with amines is called the *Boyland–Sims oxidation*. Yields are low with either phenols or amines, generally $<50\%$. The mechanisms are not clear,⁵⁴⁰ but for the Boyland–Sims oxidation there is evidence that the $S_2O_8^{2-}$ ion attacks at the ipso position, and then a migration follows.⁵⁴¹

Electrolysis of benzene, in the presence of trifluoroacetic acid and triethylamine, leads to a 73% yield of phenol.⁵⁴²

G. Metal Electrophiles

Reactions in which a metal replaces the hydrogen of an aromatic ring are considered along with their aliphatic counterparts in Chapter 12 (12-22 and 12-23).

HYDROGEN AS THE LEAVING GROUP IN REARRANGEMENT REACTIONS

In these reactions, a group is detached from a *side chain* and then attacks the ring, but in other aspects they resemble the reactions already treated in this chapter.⁵⁴³ Since a group moves from one position to another in a molecule, these are rearrangements. In all these reactions, the question arises as to whether the group that cleaves from a given molecule attacks the same molecule or another one, that is is the reaction intramolecular or intermolecular? For intermolecular reactions the mechanism is the same as ordinary aromatic substitution, but for intramolecular

cases the migrating group could never be completely free, or else it would be able to attack another molecule. Since the migrating species in intramolecular rearrangements is thus likely to remain near the atom from which it cleaved, it has been suggested that intramolecular reactions are more likely to lead to ortho products than are the intermolecular type. This characteristic has been used, among others, to help decide whether a given rearrangement is inter- or intramolecular, though there is evidence that at least in some cases, an intermolecular mechanism can still result in a high degree of ortho migration.⁵⁴⁴

The Claisen (18-33) and benzidine (18-36) rearrangements, which superficially resemble those in this section, have different mechanisms and are treated in Chapter 18.

A. Groups Cleaving from Oxygen

11-27 The Fries Rearrangement

1/C-Hydro,5/O-acyl-interchange⁵⁴⁵

Phenolic esters can be rearranged by heating with Friedel–Crafts catalysts in a synthetically useful reaction known as the *Fries rearrangement*.⁵⁴⁶ Both *o*- and *p*-acylphenols can be produced, and it is often possible to select conditions so that either one predominates. The ortho/para ratio is dependent on the temperature, solvent, and amount of catalyst used. Exceptions are known, but low temperatures generally favor the para product and high temperatures the ortho product. The R group may be aliphatic or aromatic. Any meta-directing substituent on the ring interferes with the reactions, as might be expected for a Friedel–Crafts process. In the case of aryl benzoates treated with F_3CSO_2OH , the Fries rearrangement was shown to be reversible and an equilibrium was established.⁵⁴⁷ Transition-metal-catalyzed Fries rearrangements have been reported.⁵⁴⁸

⁵⁴⁴See Dawson, I.M.; Hart, L.S.; Littler, J.S. *J. Chem. Soc. Perkin Trans. 2* **1985**, 1601.

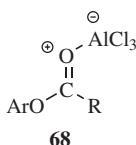

⁵⁴⁵This is the name for the para migration. For the ortho migration, the name is 1/C-hydro,3/O-acyl-interchange.

⁵⁴⁶For reviews, see Shine, H.J. *Aromatic Rearrangements*, Elsevier, NY, **1967**, pp. 72–82, 365–368; Gerecs, A., in Olah, G.A. *Friedel–Crafts and Related Reactions*, Vol. 3, Wiley, NY, **1964**, pp. 499–533. ⁵⁴⁷Effenberger, F.; Gutmann, R. *Chem. Ber.* **1982**, *115*, 1089.

⁵⁴⁸With $Sc(OTf)_3$, see Kobayashi, S.; Moriwaki, M.; Hachiya, I. *Tetrahedron Lett.* **1996**, *37*, 4183; with $ZrCl_4$ see Harrowven, D.C.; Dainty, R.F. *Tetrahedron Lett.* **1996**, *37*, 7659; with $Hf(OTf)_4$ see Kobayashi, S.; Moriwaki, M.; Hachiya, I. *Tetrahedron Lett.* **1996**, *37*, 2053. Also see Kobayashi, S.; Moriwaki, M.; Hachiya, I. *J. Chem. Soc., Chem. Commun.* **1995**, 1527.

The exact mechanism has still not been completely worked out.⁵⁴⁹ Opinions have been expressed that it is completely intermolecular,⁵⁵⁰ completely intramolecular,⁵⁵¹ and partially inter- and intramolecular.⁵⁵² One way to decide between inter- and intramolecular processes is to run the reaction of the phenolic ester in the presence of another aromatic compound, say, toluene. If some of the toluene is acylated, the reaction must be, at least in part, intermolecular. If the toluene is not acylated, the presumption is that the reaction is intramolecular, though this is not certain, for it may be that the toluene is not attacked because it is less active than the other. A number of such experiments (called *crossover experiments*) have been carried out; sometimes crossover products have been found and sometimes not. As in **11-17**, an initial complex (**68**) is formed between the substrate and the catalyst, so that a catalyst/substrate molar ratio of at least 1:1 is required. In the presence of aluminum chloride, the Fries rearrangement can be induced with microwave irradiation.⁵⁵³ Simply heating phenyl acetate with microwave irradiation gives the Fries rearrangement.⁵⁵⁴ The Fries rearrangement has been carried out in ionic melts.⁵⁵⁵

The Fries rearrangement can also be carried out with UV light, in the absence of a catalyst.⁵⁵⁶ This reaction, called the *photo-Fries rearrangement*,⁵⁵⁷ is predominantly an intramolecular free-radical process. Both ortho and para migration are observed.⁵⁵⁸ Unlike the Lewis acid-catalyzed Fries rearrangement, the photo-Fries reaction can be accomplished, though often in low yields, when meta-directing groups are on the ring. The available evidence strongly suggests the following

⁵⁵⁸The migration can be made almost entirely ortho by cyclodextrin encapsulation (see p. 129): Syamala, M.S.; Rao, B.N.; Ramamurthy, V. *Tetrahedron* **1988**, *44*, 7234. See also, Veglia, A.V.; Sanchez, A.M.; de Rossi, R.H. *J. Org. Chem.* **1990**, *55*, 4083.

mechanism involving formation of the excited state ester followed by dissociation to a radical pair⁵⁵⁹ for the photo-Fries rearrangement⁵⁶⁰ (illustrated for para attack).

The phenol ArOH is always a side product, resulting from some ArO• that leaks from the solvent cage and abstracts a hydrogen atom from a neighboring molecule. When the reaction was performed on phenyl acetate in the gas phase, where there are no solvent molecules to form a cage (but in the presence of isobutane as a source of abstractable hydrogens), phenol was the chief product and virtually no *o*- or *p*-hydroxyacetophenone was found.⁵⁶¹ Other evidence⁵⁶² for the mechanism is that CIDNP has been observed during the course of the reaction⁵⁶³ and that the ArO• radical has been detected by flash photolysis⁵⁶⁴ and by nanosecond time-resolved Raman spectroscopy.⁵⁶⁵

Treatment of *O*-arylsulfonate esters with AlCl₃–ZnCl₂, on silica with microwave irradiation, leads to 2-sulfonyl phenols in a thia-Fries rearrangement.⁵⁶⁶ A similar reaction was reported with *O*-arylsulfonamides.⁵⁶⁷

OS II, 543; III, 280, 282.

B. Groups Cleaving from Nitrogen⁵⁶⁸

It has been shown that PhNH₂D rearranges to *o*- and *p*-deuterioaniline.⁵⁶⁹ The migration of OH, formally similar to reactions **11-28–11-32**, is a nucleophilic substitution and is treated in Chapter 13 (**13-32**).

⁵⁵⁹Proposed by Kobsa, H. *J. Org. Chem.* **1962**, 27, 2293.

⁵⁶⁰It has been suggested that a second mechanism, involving a four-center transition state, is also possible: Bellus, D.; Schaffner, K.; Hoigné, J. *Helv. Chim. Acta* **1968**, 51, 1980; Sander, M.R.; Hedaya, E.; Trecker, D.J. *J. Am. Chem. Soc.* **1968**, 90, 7249; Belluš, D. *Adv. Photochem.* **1971**, 8, 109.

11-28 Migration of the Nitro Group

1/C-Hydro,3/N-nitro-interchange

N-Nitro aromatic amines rearrange on treatment with acids to *o*- and *p*-nitroamines with the ortho compounds predominating.⁵⁷⁰ Aside from this indication of an intramolecular process, there is also the fact that virtually no meta isomer is produced in this reaction,⁵⁷¹ although direct nitration of an aromatic amine generally gives a fair amount of meta product. Thus a mechanism in which NO_2^+ is dissociated from the ring, and then attacks another molecule must be ruled out. Further results indicating an intramolecular process include the observation that rearrangement of several substrates in the presence of K^{15}NO_3 gave products containing no ^{15}N ,⁵⁷² and that rearrangement of a mixture of $\text{PhNH}^{15}\text{NO}_2$ and unlabeled *p*- $\text{MeC}_6\text{H}_4\text{NHNO}_2$ gave 2-nitro-4-methylaniline containing no ^{15}N .⁵⁷³ On the other hand, rearrangement of **69** in the presence of

unlabeled PhNMeNO_2 gave labeled **70**, which did not arise by displacement of F.⁵⁷⁴ The R group may be hydrogen or alkyl. Two principal mechanisms have been suggested, one involving cyclic attack by the oxygen of the nitro group at the ortho position before the group cleaves,⁵⁷⁵ and the other involving a cleavage into a

⁵⁷⁰For reviews, see Williams, D.L.H., in Patai, S. *The Chemistry of Functional Groups, Supplement F*, pt. 1, Wiley, NY, **1982**, pp. 127–153; White, W.N. *Mech. Mol. Migr.* **1971**, 3, 109–143; Shine, H.J. *Aromatic Rearrangements*, Elsevier, NY, **1967**, pp. 235–249.

radical and a radical ion held together in a solvent cage.⁵⁷⁶ Among the evidence for the latter view⁵⁷⁷ are

the effects of substituents on the rate of the reaction,⁵⁷⁸ ¹⁵N and ¹⁴C kinetic isotope effects that show non-concertedness,⁵⁷⁹ and the fact that both *N*-methylaniline and nitrous acid are produced in sizable and comparable amounts in addition to the normal products *o*- and *p*-nitro-*N*-methylaniline.⁵⁸⁰ These side products are formed when the radicals escape from the solvent cage.

11-29 Migration of the Nitroso Group: The Fischer–Hepp Rearrangement

1/C-Hydro-5/*N*-nitroso-interchange

The migration of a nitroso group, formally similar to **11-28**, is important because *p*-nitroso secondary aromatic amines cannot generally be prepared by direct *C*-nitrosation of secondary aromatic amines (see **12-50**). The reaction, known as the *Fischer–Hepp rearrangement*,⁵⁸¹ is brought about by treatment of *N*-nitroso secondary aromatic amines with HCl. Other acids give poor or no results. In benzene systems the para product is usually formed exclusively.⁵⁸² The mechanism of the rearrangement is not completely understood. The fact that the reaction takes place in a large excess of urea⁵⁸³ shows that it is intramolecular⁵⁸⁴ since, if NO⁺, NOCl,

or some similar species were free in the solution, it would be captured by the urea, preventing the rearrangement.

11-30 Migration of an Arylazo Group

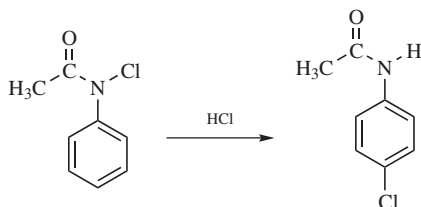

1/C-Hydro-5/N-arylazo-interchange

Rearrangement of aryl triazenes can be used to prepare azo derivatives of primary and secondary aromatic amines.⁵⁸⁵ These are first diazotized at the amino group (see **11-4**) to give triazenes, which are then rearranged by treatment with acid. The rearrangement always gives the para isomer, unless that position is occupied.

11-31 Migration of Halogen: The Orton Rearrangement

1/C-Hydro-5/N-halo-interchange

Migration of a halogen from a nitrogen side chain to the ring by treatment with HCl is called the *Orton rearrangement*.⁵⁸⁶ The main product is the para isomer, though some ortho product may also be formed. The reaction has been carried out with *N*-chloro- and *N*-bromoamines and less often with *N*-iodo compounds. The amine must be acylated, except that PhNCl₂ gives 2,4-dichloroaniline. The reaction is usually performed in water or acetic acid. There is considerable evidence (cross-halogenation, labeling, etc.) that this is an intermolecular process.⁵⁸⁷ First, the HCl reacts with the starting material to give ArNHCOCH₃ and Cl₂; then the chlorine halogenates the ring as in **11-10**. Among the evidence is that chlorine has been isolated from the reaction mixture. The Orton rearrangement can also

⁵⁸⁵For a review, see Shine, H.J. *Aromatic Rearrangements*, Elsevier, NY, **1967**, pp. 212–221.

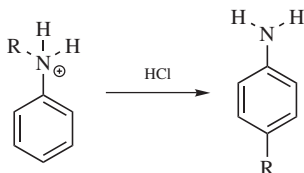

⁵⁸⁶For reviews, see Shine, H.J. *Aromatic Rearrangements*, Elsevier, NY, **1967**, pp. 221–230, 362–364; Bieron, J.F.; Dinan, F.J., in Zabicky, J. *The Chemistry of Amides*, Wiley, NY, **1970**, pp. 263–269.

⁵⁸⁷The reaction has been found to be intramolecular in aprotic solvents: Golding, P.D.; Reddy, S.; Scott, J.M.W.; White, V.A.; Winter, J.G. *Can. J. Chem.* **1981**, *59*, 839.

be brought about photochemically⁵⁸⁸ and by heating in the presence of benzoyl peroxide.⁵⁸⁹ These are free-radical processes.

11-32 Migration of an Alkyl Group⁵⁹⁰

1/C-Hydro-5/N-alkyl-interchange

When HCl salts of arylalkylamines are heated at $\sim 200\text{--}300^\circ\text{C}$, migration occurs in what is called the *Hofmann–Martius reaction*. It is an intermolecular reaction, since crossing is found. For example, methylanilinium bromide gave not only the normal products *o*- and *p*-toluidine but also aniline and di- and trimethylanilines.⁵⁹¹ As would be expected for an intermolecular process, there is isomerization when R is primary.

With primary R, the reaction probably goes through the alkyl halide formed initially in an $\text{S}_{\text{N}}2$ reaction:

Evidence for this view is that alkyl halides have been isolated from the reaction mixture and that Br^- , Cl^- , and I^- gave different ortho/para ratios, which indicates that the halogen is involved in the reaction.⁵⁹¹ Further evidence is that the alkyl halides isolated are not rearranged (as would be expected if they are formed by an $\text{S}_{\text{N}}2$ mechanism), even though the alkyl groups in the ring are rearranged. Once the alkyl halide is formed, it reacts with the substrate by a normal Friedel–Crafts alkylation process (11-11), accounting for the rearrangement. When R is secondary or tertiary, carbocations may be directly formed so that the reaction does not go through the alkyl halides.⁵⁹²

It is also possible to carry out the reaction by heating the amine (not the salt) at a temperature between 200 and 350°C with a metal halide, such as CoCl_2 , CdCl_2 , or ZnCl_2 . When this is done, the reaction is called the *Reilly–Hickinbottom rearrangement*. Primary R groups larger than ethyl give both rearranged and unrearranged products.⁵⁹³ The reaction is not generally useful for secondary and tertiary R groups, which are usually cleaved to alkenes under these conditions.

⁵⁸⁸For example, see Hodges, F.W. *J. Chem. Soc.* **1933**, 240.

⁵⁸⁹For example, Ayad, K.N.; Beard, C.; Garwood, R.F.; Hickinbottom, W.J. *J. Chem. Soc.* **1957**, 2981; Coulson, J.; Williams, G.H.; Johnston, K.M. *J. Chem. Soc. B* **1967**, 174.

⁵⁹³For example, see Birchal, J.M.; Clark, M.T.; Goldwhite, H.; Thorpe, D.H. *J. Chem. Soc. Perkin Trans. 1* **1972**, 2579.

When acylated arylamines are photolyzed, migration of an acyl group takes place⁵⁹⁴ in a process that resembles the photo-Fries reaction (11-27).

OTHER LEAVING GROUPS

Three types of reactions are considered in this section.

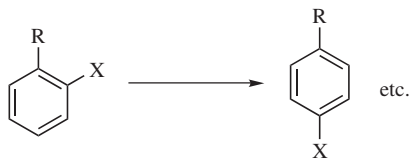

1. Reactions in which hydrogen replaces another leaving group:

2. Reactions in which an electrophile other than hydrogen replaces another leaving group:

3. Reactions in which a group (other than hydrogen) migrates from one position in a ring to another. Such migrations can be either inter- or intramolecular:

The three types are not treated separately, but reactions are classified by leaving group.

A. Carbon Leaving Groups

11-33 Reversal of Friedel–Crafts Alkylation

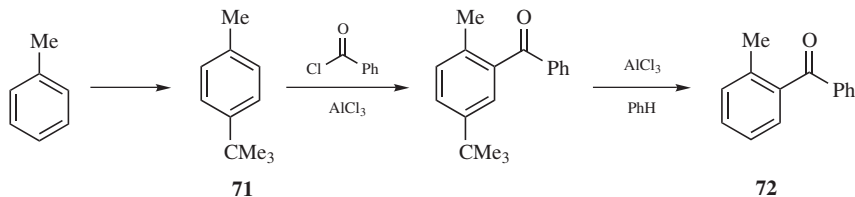

Hydro-de-alkylation or Dealkylation

Alkyl groups can be cleaved from aromatic rings by treatment with proton and/or Lewis acids. Tertiary R groups are the most easily cleaved; because this is true, the *tert*-butyl group is occasionally introduced into a ring, used to direct another

⁵⁹⁴For examples see Elad, D.; Rao, D.V.; Stenberg, V.I. *J. Org. Chem.* **1965**, *30*, 3252; Shizuka, H.; Tanaka, I. *Bull. Chem. Soc. Jpn.* **1968**, *41*, 2343; **1969**, *42*, 909; Fischer, M. *Tetrahedron Lett.* **1968**, 4295; Hageman, H.J. *Recl. Trav. Chim. Pays-Bas* **1972**, *91*, 1447; Chênevert, R.; Plante, R. *Can. J. Chem.* **1983**, *61*, 1092; Abdel-Malik, M.M.; de Mayo, P. *Can. J. Chem.* **1984**, *62*, 1275; Nassetta, M.; de Rossi, R.H.; Cosa, J.J. *Can. J. Chem.* **1988**, *66*, 2794.

group, and then removed.⁵⁹⁵ For example, 4-*tert*-butyltoluene (**71**) reacted with benzoyl chloride and AlCl₃ to give the acylated product, and subsequent treatment with AlCl₃ led to loss of the *tert*-butyl group to give **72**.⁵⁹⁶

Secondary R groups are harder to cleave, and primary R harder still. Because of this reaction, care must be taken when using Friedel–Crafts catalysts (Lewis or proton acids) on aromatic compounds containing alkyl groups. True cleavage, in which the R becomes an alkene, occurs only at high temperatures, >400°C.⁵⁹⁷ At ordinary temperatures, the R group attacks another ring, so that the bulk of the product may be dealkylated, but there is a residue of heavily alkylated material. The isomerization reaction, in which a group migrates from one position in a ring to another or to a different ring, is therefore more important than true cleavage. In these reactions, the meta isomer is generally the most favored product among the dialkylbenzenes; and the 1,3,5 product the most favored among the trialkylbenzenes, because they have the highest thermodynamic stabilities. Alkyl migrations can be inter- or intramolecular, depending on the conditions and on the R group. The following experiments can be cited: Ethylbenzene treated with HF and BF₃ gave, almost completely, benzene and diethylbenzenes⁵⁹⁸ (entirely intermolecular); propylbenzene labeled in the β position gave benzene, propylbenzene, and di- and tripropylbenzenes, but the propylbenzene recovered was partly labeled in the α position and not at all in the γ position⁵⁹⁹ (both intra- and intermolecular); *o*-xylene treated with HBr and AlBr₃ gave a mixture of *o*- and *m*-, but no *p*-xylene, while *p*-xylene gave *p*- and *m*-, but no *o*-xylene, and no trimethyl compounds could be isolated in these experiments⁶⁰⁰ (exclusively intramolecular rearrangement). Apparently, methyl groups migrate only intramolecularly, while other groups may follow either path.⁶⁰¹

The mechanism⁶⁰² of intermolecular rearrangement can involve free alkyl cations, but there is much evidence to show that this is not necessarily the case. For example, many of them occur without rearrangement within the alkyl group. The following mechanism has been proposed for intermolecular rearrangement without the involvement of carbocations that are separated from the ring.⁶⁰³

Evidence for this mechanism is that optically active PhCHDCH₃ labeled in the ring with ¹⁴C and treated with GaBr₃ in the presence of benzene gave ethylbenzene containing no deuterium and two deuterium atoms and that the rate of loss of radioactivity was about equal to the rate of loss of optical activity.⁶⁰³ The mechanism of intramolecular rearrangement is not very clear. 1,2-shifts of this kind have been proposed:⁶⁰⁴

There is evidence from ¹⁴C labeling that intramolecular migration occurs only through 1,2-shifts.⁶⁰⁵ Any 1,3 or 1,4 migration takes place by a series of two or more 1,2-shifts.

Phenyl groups have also been found to migrate. Thus *o*-terphenyl, heated with AlCl₃-H₂O, gave a mixture containing 7% *o*-, 70% *m*-, and 23% *p*-terphenyl.⁶⁰⁶ Alkyl groups have also been replaced by groups other than hydrogen (e.g., nitro groups).

Unlike alkylation, *Friedel-Crafts acylation* has been generally considered to be irreversible, but a number of instances of electrofugal acyl groups have been reported,⁶⁰⁷ especially where there are two ortho substituents, for example the

hydro-de-benzoylation of **73**.⁶⁰⁸

OS V, 332. Also see OS III, 282, 653; V, 598.

11-34 Decarbonylation of Aromatic Aldehydes

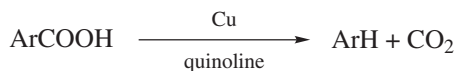

Hydro-de-formylation or Deformylation

The decarbonylation of aromatic aldehydes with sulfuric acid⁶⁰⁹ is the reverse of the *Gatterman–Koch reaction* (11-18). It has been carried out with trialkyl- and trialkoxybenzaldehydes. The reaction takes place by the ordinary arenium ion mechanism: the attacking species is H^+ and the leaving group is HCO^+ , which can lose a proton to give CO or combine with OH^- from the water solvent to give formic acid.⁶¹⁰ Aromatic aldehydes have also been decarbonylated with basic catalysts.⁶¹¹ When basic catalysts are used, the mechanism is probably similar to the $\text{S}_{\text{E}}1$ process of 11-35 (see also 14-32).

11-35 Decarboxylation of Aromatic Acids

Hydro-de-carboxylation or Decarboxylation

The decarboxylation of aromatic acids is most often carried out by heating with copper and quinoline. However, two other methods can be used with certain substrates. In one method the salt of the acid (ArCOO^-) is heated, and in the other the carboxylic acid is heated with a strong acid, often sulfuric. The latter method is accelerated by the presence of electron-donating groups in ortho and para positions

and by the steric effect of groups in the ortho positions; in benzene systems it is generally limited to substrates that contain such groups. In this method, decarboxylation takes place by the arenium ion mechanism,⁶¹² with

H^+ as the electrophile and CO_2 as the leaving group.⁶¹³ Evidently, the order of electrofugal ability is $\text{CO}_2 > \text{H}^+ > \text{COOH}^+$, so that it is necessary, at least in most cases, for the COOH to lose a proton before it can cleave.

When carboxylate ions are decarboxylated, the mechanism is entirely different, being of the $\text{S}_{\text{E}}1$ type. Evidence for this mechanism is that the reaction is first order and that electron-withdrawing groups, which would stabilize a carbanion, facilitate the reaction.⁶¹⁴

Despite its synthetic importance, the mechanism of the copper–quinoline method has been studied very little, but it has been shown that the actual catalyst is cuprous ion.⁶¹⁵ In fact, the reaction proceeds much faster if the acid is heated in quinoline with cuprous oxide instead of copper, provided that atmospheric oxygen is rigorously excluded. A mechanism has been suggested in which it is the cuprous salt of the acid that actually undergoes the decarboxylation.⁶¹⁵ It has been shown that cuprous salts of aromatic acids are easily decarboxylated by heating in quinoline⁶¹⁶ and that aryl-copper compounds are intermediates that can be isolated in some cases.⁶¹⁷ Metallic silver has been used in place of copper, with higher yields.⁶¹⁸

⁶¹²For a review, see Taylor, R., in Bamford, C.H.; Tipper, C.F.H. *Comprehensive Chemical Kinetics*, Vol. 13, Elsevier, NY, **1972**, pp. 303–316. For a review of isotope effect studies of this reaction, see Willi, A.V. *Isot. Org. Chem.* **1977**, *3*, 257.

⁶¹³See, for example, Los, J.M.; Rekker, R.F.; Tonsbeeck, C.H.T. *Recl. Trav. Chim. Pays-Bas* **1967**, *86*, 622; Huang, H.H.; Long, F.A. *J. Am. Chem. Soc.* **1969**, *91*, 2872; Willi, A.V.; Cho, M.H.; Won, C.M. *Helv. Chim. Acta* **1970**, *53*, 663.

⁶¹⁷For example, see Ibne-Rasa, K.M. *J. Am. Chem. Soc.* **1962**, *84*, 4962; Tedder, J.M.; Theaker, G. *J. Chem. Soc.* **1959**, 257.

⁶¹⁸Chodowska-Palicka, J.; Nilsson, M. *Acta Chem. Scand.* **1970**, *24*, 3353.

In certain cases, the carboxyl group can be replaced by electrophiles other than hydrogen, for example NO,⁶¹⁸ I,⁶¹⁹ Br,⁶²⁰ or Hg.⁶²¹

Rearrangements are also known to take place. For example, when the phthalate ion is heated with a catalytic amount of cadmium, the terphthalate ion (**74**) is produced.⁶²²

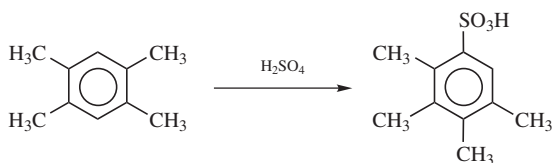

In a similar process, potassium benzoate heated with cadmium salts disproportionates to benzene and **74**. The term *Henkel reaction* (named for the company that patented the process) is used for these rearrangements.⁶²³ An S_E1 mechanism has been suggested.⁶²⁴ The terphthalate is the main product because it crystallizes from the reaction mixture, driving the equilibrium in that direction.⁶²⁵

For aliphatic decarboxylation, see **12-40**.

11-36 The Jacobsen Reaction

When polyalkyl- or polyhalobenzenes are treated with sulfuric acid, the ring is sulfonated, but rearrangement also takes place. The reaction, known as the *Jacobsen reaction*, is limited to benzene rings that have at least four substituents, which can be any combination of alkyl and halogen groups, where the alkyl groups can be

⁶²⁵Ratusky, J. *Collect. Czech. Chem. Commun.* **1968**, *33*, 2346.

ethyl or methyl and the halogen iodo, chloro, or bromo. When isopropyl or *tert*-butyl groups are on the ring, these groups are cleaved to give alkenes. Since a sulfo group can later be removed (**11-38**), the Jacobsen reaction can be used as a means of rearranging polyalkylbenzenes. The rearrangement always brings the alkyl or halo groups closer together than they were originally. Side products in the case illustrated above are pentamethylbenzenesulfonic acid, 2,4,5-trimethylbenzenesulfonic acid, and so on, indicating an intermolecular process, at least partially.

The mechanism of the Jacobsen reaction is not established,⁶²⁶ but there is evidence, at least for polymethylbenzenes, that the rearrangement is intermolecular, and that the species to which the methyl group migrates is a polymethylbenzene, not a sulfonic acid. Sulfonation takes place after the migration.⁶²⁷ It has been shown by labeling that ethyl groups migrate without internal rearrangement.⁶²⁸

Isomerization of alkyl groups in substituted biphenyls has been observed⁶²⁹ when the medium is a superacid (see p. 236).

B. Oxygen Leaving Groups

11-37 Deoxygenation

In a few cases, it is possible to remove an oxygen substituent directly from the aromatic ring. Treatment of an aryl mesylate (ArOMs) with a nickel catalyst in DMF, for example, leads to the deoxygenated product, Ar-H.⁶³⁰

C. Sulfur Leaving Groups

11-38 Desulfonation or Hydro-de-sulfonation

The cleavage of sulfo groups from aromatic rings is the reverse of **11-7**.⁶³¹ By the principle of microscopic reversibility, the mechanism is also the reverse.⁶³² Dilute H₂SO₄ is generally used, as the reversibility of sulfonation decreases with

⁶³²For a discussion, see Kozlov, V.A.; Bagrovskaya, N.A. *J. Org. Chem. USSR* **1989**, 25, 1152.

increasing H₂SO₄ concentration. The reaction permits the sulfo group to be used as a blocking group to direct meta and then to be removed. The sulfo group has also been replaced by nitro and halogen groups. Sulfo groups have also been removed from the ring by heating with an alkaline solution of Raney nickel.⁶³³ In another catalytic process, aromatic sulfonyl bromides or chlorides are converted to aryl bromides or chlorides, respectively, on heating with chlorotris(triphenylphosphine) rhodium(I).⁶³⁴ This reaction is similar to the decarbonylation of aromatic acyl halides mentioned in **14-32**.

OS I, 388; II, 97; III, 262; IV, 364. Also see OS I, 519; II, 128; V, 1070.

D. Halogen Leaving groups

11-39 Dehalogenation or Hydro-de-halogenation

Aryl halides can be dehalogenated by Friedel–Crafts catalysts. Iodine is the most easily cleaved. Dechlorination is seldom performed and defluorination apparently never. The reaction is most successful when a reducing agent, say, Br[−] or I[−] is present to combine with the I⁺ or Br⁺ coming off.⁶³⁵ Except for deiodination, the reaction is seldom used for preparative purposes. Migration of halogen is also found,⁶³⁶ both intramolecular⁶³⁷ and intermolecular.⁶³⁸ The mechanism is probably the reverse of that of **11-10**.⁶³⁹ Debromination of aromatic rings having two attached amino groups was accomplished by refluxing in aniline containing acetic acid/HBr.⁶⁴⁰

Rearrangement of polyhalobenzenes can also be catalyzed by very strong bases; for example 1,2,4-tribromobenzene is converted to 1,3,5-tribromobenzene by treatment with PhNHK.⁶⁴¹ This reaction, which involves aryl carbanion intermediates (S_E1 mechanism), has been called the *halogen dance*.⁶⁴²

Removal of halogen from aromatic rings can also be accomplished by various reducing agents, among them Bu_3SnH ,⁶⁴³ catalytic hydrogenolysis,⁶⁴⁴ catalytic transfer hydrogenolysis,⁶⁴⁵ $\text{Fe}(\text{CO})_5$,⁶⁴⁶ Na-Hg in liquid NH_3 ,⁶⁴⁷ LiAlH_4 ,⁶⁴⁸ LiAlH_4 and a NbCl_5 catalyst,⁶⁴⁹ NaBH_4 and a catalyst,⁶⁵⁰ Ni/C with $\text{Me}_2\text{NH}\cdot\text{BH}_3$,⁶⁵¹ NaH ,⁶⁵² HCOOH ⁶⁵³ or aqueous HCOO^- ⁶⁵⁴ with Pd/C , and Raney nickel in alkaline solution,⁶⁵⁵ the last method being effective for fluorine, as well as for the other halogens. Carbon monoxide, with potassium tetracarbonylhydrideferate $\text{KHF}(\text{CO})_4$ as a catalyst, specifically reduces aryl iodides.⁶⁵⁶ Polymethylhydrosiloxane (PHMS) and KF , with a palladium catalyst, also reduces aryl iodides.⁶⁵⁷ Not all these reagents operate by electrophilic substitution mechanisms. Some are nucleophilic substitutions and some are free-radical processes. Photochemical⁶⁵⁸ and electrochemical⁶⁵⁹ reduction are also known. Halogen can also be removed from aromatic rings indirectly by conversion to Grignard reagents (**12-38**) followed by hydrolysis (**11-41**).

These reactions are considered along with their aliphatic counterparts at reactions **12-38** and **12-39**.

E. Metal Leaving Groups

11-41 Hydrolysis of Organometallic Compounds

Hydro-de-metallation or Demetallation

Organometallic compounds can be hydrolyzed by acid treatment. For active metals, such as Mg, Li, and so on water is sufficiently acidic. The most important example of this reaction is hydrolysis of Grignard reagents, but M may be many other metals or metalloids. Examples are SiR_3 , HgR, Na, and $\text{B}(\text{OH})_2$. Since aryl Grignard and aryllithium compounds are fairly easy to prepare, they are often used to prepare salts of weak acids, such as alkynes.

Where the bond between the metal and the ring is covalent, the usual arenium ion mechanism operates.⁶⁶⁰ Where the bonding is essentially ionic, this is a simple acid-base reaction. For the aliphatic counterpart of this reaction, see reaction **12-24**.

Other reactions of aryl organometallic compounds are treated with their aliphatic analog: reactions **12-25-12-27** and **12-30-12-37**.

⁶⁶⁰For a discussion of the mechanism, see Taylor, R., in Bamford, C.H.; Tipper, C.F.H. *Comprehensive Chemical Kinetics*, Vol. 13, Elsevier, NY, **1972**, pp. 278-303, 324-349.

Aliphatic, Alkenyl, and Alkynyl Substitution, Electrophilic and Organometallic

In Chapter 11, it was pointed out that the most important leaving groups in electrophilic substitution are those that can best exist with an outer shell that is deficient in a pair of electrons. For aromatic systems, the most common leaving group is the proton. The proton is also a leaving group in aliphatic systems, but the reactivity depends on the acidity. Protons in saturated alkanes are very unreactive, but electrophilic substitutions are often easily carried out at more acidic positions, for example, α to a carbonyl group, or at an alkynyl position ($\text{RC}\equiv\text{CH}$). Since metallic ions are easily able to bear positive charges, we might expect that organometallic compounds would be especially susceptible to electrophilic substitution, and this is indeed the case.¹ Another important type of electrophilic substitution, known as *anionic cleavage*, involves the breaking of C–C bonds; in these reactions there are carbon leaving groups (12-40–12-46). A number of electrophilic substitutions at a nitrogen atom are treated at the end of the chapter.

Since a carbanion is what remains when a positive species is removed from a carbon atom, the subject of carbanion structure and stability (Chapter 5) is inevitably related to the material in this chapter. So is the subject of very weak acids and very strong bases (Chapter 8), because the weakest acids are those in which the hydrogen is bonded to carbon.

Rev.* 1980, 9, 25, and in Tsutsui, M. *Characterization of Organometallic Compounds*, Wiley, NY, 1969–1971, the articles by Cartledge, F.K.; Gilman, H. pt. 1, pp. 1–33, and by Reichle, W.T. pt. 2, pp. 653–826.

MECHANISMS

For aliphatic electrophilic substitution, we can distinguish at least four possible major mechanisms,² which we call S_E1, S_E2 (front), S_E2 (back), and S_Ei. The S_E1 is unimolecular; the other three are bimolecular. It is noted that the term “S_EAr” has been proposed to represent electrophilic aromatic substitution, so that the term “S_E2” refers exclusively to electrophilic substitutions where a steric course is possible.³ To describe the steric course of an aliphatic substitution reaction, the suffixes “ret” and “inv” were proposed, referring to retention and inversion of configuration, respectively.

BIMOLECULAR MECHANISMS. S_E2 AND S_Ei

The bimolecular mechanisms for electrophilic aliphatic substitution are analogous to the S_N2 mechanism in that the new bond forms as the old one breaks. However, in the S_N2 mechanism the incoming group brings with it a pair of electrons, and this orbital can overlap with the central carbon only to the extent that the leaving group takes away its electrons; otherwise the carbon would have more than eight electrons at once in its outer shell. Since electron clouds repel, this means also that the incoming group attacks backside, at a position 180° from the leaving group, resulting in inversion of configuration. When the nucleophilic species attacks (donates electrons to) an electrophile, which brings to the substrate only a vacant orbital, predicting the direction the attack is not as straightforward. We can imagine two main possibilities: delivery of the electrophile to the front, which we call S_E2 (front), and delivery of the electrophile to the rear, which we call S_E2 (back). The possibilities can be pictured (charges not shown):

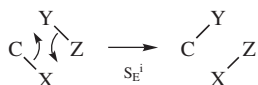

Both the S_E2 (front) and S_E2 (back) mechanisms are designated D_EA_E in the IUPAC system. With substrates in which we can distinguish the possibility, the former

³Gawley, R.E. *Tetrahedron Lett.* 1999, 40, 4297.

mechanism should result in retention of configuration and the latter in inversion. The reaction of allylsilanes with adamantyl chloride and TiCl_4 , for example, gives primarily the antiprodut via a $\text{S}_{\text{E}}2'$ reaction.⁴ When the electrophile reacts from the front, there is a third possibility. A portion of the electrophile may assist in the removal of the leaving group, forming a bond with it at the same time that the new C–Y bond is formed:

This mechanism, which we call the S_{Ei} mechanism⁵ (IUPAC designation: *cyclo-D_EA_ED_nA_n*), also results in retention of configuration.⁶ Plainly, where a second-order mechanism involves this kind of internal assistance, backside attack is impossible.

It is evident that these three mechanisms are not easy to distinguish. All three give second-order kinetics, and two result in retention of configuration.⁷ In fact, although much work has been done on this question, there are few cases in which we can unequivocally say that one of these three and not another is actually

taking place. Clearly, a study of the stereochemistry can distinguish between $\text{S}_{\text{E}}2$ (back) on the one hand and $\text{S}_{\text{E}}2$ (front) or S_{Ei} on the other. Many such investigations have been made. In the overwhelming majority of second-order electrophilic substitutions, the result has been retention of configuration or some other indication of frontside attack, indicating an $\text{S}_{\text{E}}2$ (front) or S_{Ei} mechanism. For example, when *cis*-1 was treated with labeled mercuric chloride, the **2** produced was 100% *cis*. The bond between the mercury and the ring must have been broken (as well as the other Hg–C bond), since each of the products contained about half of the labeled mercury.⁸ Another indication of frontside attack is that second-order

⁴Buckle, M.J.C.; Fleming, I.; Gil, S. *Tetrahedron Lett.* **1992**, 33, 4479.

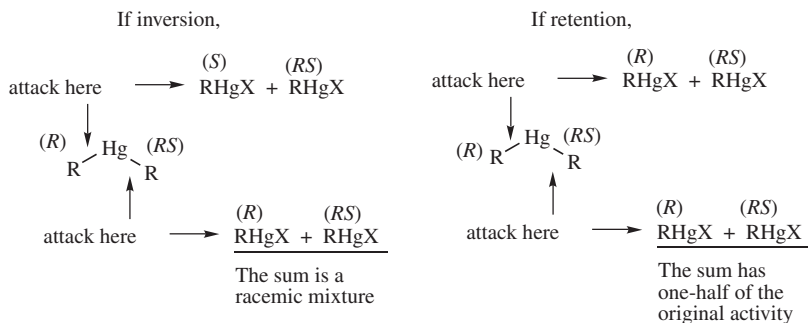

⁵The names for these mechanisms vary throughout the literature. For example, the S_{Ei} mechanism has also been called the $\text{S}_{\text{F}}2$, the $\text{S}_{\text{E}}2$ (closed), and the $\text{S}_{\text{E}}2$ (cyclic) mechanism. The original designations, $\text{S}_{\text{E}}1$, $\text{S}_{\text{E}}2$, and so on, were devised by the Hughes–Ingold school.

⁶It has been contended that the S_{Ei} mechanism violates the principle of conservation of orbital symmetry (p. 1208), and that the $\text{S}_{\text{E}}2$ (back) mechanism partially violates it: Slack, D.A.; Baird, M.C. *J. Am. Chem. Soc.* **1976**, 98, 5539.

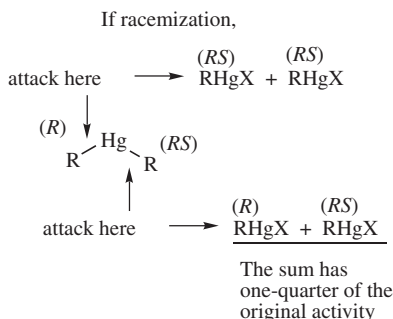

⁷For a review of the stereochemistry of reactions in which a carbon-transition-metal σ bond is formed or broken, see Flood, T.C. *Top. Stereochem.* **1981**, 12, 37. See also Jensen, F.R.; Davis, D.D. *J. Am. Chem. Soc.* **1971**, 93, 4048.

⁸Winstein, S.; Traylor, T.G.; Garner, C.S. *J. Am. Chem. Soc.* **1955**, 77, 3741.

electrophilic substitutions proceed very easily at *bridgehead* carbons (see p. 429).⁹ Still another indication is the behavior of neopentyl as a substrate. S_N2 reactions at neopentyl are extremely slow (p. 479), because attack from the rear is blocked and the transition state for the reaction lies very high in energy. The fact that neopentyl systems undergo electrophilic substitution only slightly more slowly than ethyl¹⁰ is further evidence for frontside attack. One final elegant experiment may be noted.

The compound di-*sec*-butylmercury was prepared with one *sec*-butyl group optically active and the other racemic.¹¹ This was accomplished by treatment of optically active *sec*-butylmercuric bromide with racemic *sec*-butylmagnesium bromide. The di-*sec*-butyl compound was then treated with mercuric bromide to give 2 equivalents of *sec*-butylmercuric bromide. The steric course of the reaction could then be predicted by the following analysis, assuming that the bonds between the mercury and each carbon have a 50% chance of breaking. The original activity referred to is the activity of the optically active *sec*-butylmercuric bromide used to make the dialkyl compound. The actual result was that, under several different sets of conditions, the product had one-half of the original activity, demonstrating retention of configuration.

⁹Winstein, S.; Traylor, T.G. *J. Am. Chem. Soc.* **1956**, 78, 2597; Schöllkopf, U. *Angew. Chem.* **1960**, 72, 147. For a discussion, see Fort Jr., R.C.; Schleyer, P.v.R. *Adv. Alicyclic Chem.* **1966**, 1, 283, pp. 353–370.

¹⁰Hughes, E.D.; Volger, H.C. *J. Chem. Soc.* **1961**, 2359.

¹¹Jensen, F.R. *J. Am. Chem. Soc.* **1960**, 82, 2469; Ingold, C.K. *Helv. Chim. Acta* **1964**, 47, 1191.

However, inversion of configuration has been found in certain cases, demonstrating that the S_E2 (back) mechanism can take place. For example, the reaction of optically active *sec*-butyltrineopentyltin with bromine (**12-40**) gives inverted *sec*-butyl bromide.¹² A number of other organometallic compounds have also been shown to give inversion when treated with halogens,¹³ although others do not.¹⁴ So far, no inversion has been found with an organomercury substrate. It may be that still other examples of backside

attack exist,¹⁵ but have escaped detection because of the difficulty in preparing compounds with a configurationally stable carbon–metal bond. Compounds that are chiral because of a stereogenic carbon at which a carbon–metal bond is located¹⁶ are often difficult to resolve and once resolved are often easily racemized. The resolution has been accomplished most often with organomercury compounds,¹⁷ and most stereochemical investigations have therefore been made with these substrates. Only a few optically active Grignard reagents have been prepared¹⁸ (i.e., in which the only stereogenic center is the carbon bonded to the magnesium). Because of this, the steric course of electrophilic substitutions at the C–Mg bond has not often been determined. However, in one such case, the reaction of both the *exo* and *endo* isomers of the 2-norbornyl Grignard reagent with HgBr₂ (to give 2-norbornylmercuric bromide) has been shown to proceed with retention of configuration.¹⁹ It is likely that inversion takes place only when steric hindrance

¹²Jensen, F.R.; Davis, D.D. *J. Am. Chem. Soc.* **1971**, *93*, 4048. For a review of the stereochemistry of S_E2 reactions with organotin substrates, see Fukuto, J.M.; Jensen, F.R. *Acc. Chem. Res.* **1983**, *16*, 177.

¹³For example, See Applequist, D.E.; Chmurny, G.N. *J. Am. Chem. Soc.* **1967**, *89*, 875; Glaze, W.H.; Selman, C.M.; Ball Jr., A.L.; Bray, L.E. *J. Org. Chem.* **1969**, *34*, 641; Brown, H.C.; Lane, C.F. *Chem. Commun.* **1971**, 521; Jensen, F.R.; Madan, V.; Buchanan, D.H. *J. Am. Chem. Soc.* **1971**, *93*, 5283; Espenson, J.H.; Williams, D.A. *J. Am. Chem. Soc.* **1974**, *96*, 1008; Bock, P.L.; Boschetto, D.J.; Rasmussen, J.R.; Demers, J.P.; Whitesides, G.M. *J. Am. Chem. Soc.* **1974**, *96*, 2814; Magnuso, R.H.; Halpern, J.; Levitin, I.Ya.; Vol'pin, M.E. *J. Chem. Soc. Chem. Commun.* **1978**, 44.

¹⁴See, for example, Rahm, A.; Pereyre, M. *J. Am. Chem. Soc.* **1977**, *99*, 1672; McGahey, L.F.; Jensen, F.R. *J. Am. Chem. Soc.* **1979**, *101*, 4397. Electrophilic bromination of certain organotin compounds was found to proceed with inversion favored for equatorial and retention for axial C–Sn bonds: Olszowy, H.A.; Kitching, W. *Organometallics* **1984**, *3*, 1676. For a similar result, see Rahm, A.; Grimeau, J.; Pereyre, M. *J. Organomet. Chem.* **1985**, *286*, 305.

¹⁵Cases of inversion involving replacement of a metal by a metal have been reported. See Tada, M.; Ogawa, H. *Tetrahedron Lett.* **1973**, 2639; Fritz, H.L.; Espenson, J.H.; Williams, D.A.; Molander, G.A. *J. Am. Chem. Soc.* **1974**, *96*, 2378; Gielen, M.; Fosty, R. *Bull. Soc. Chim. Belg.* **1974**, *83*, 333; Bergbreiter, D.E.; Rainville, D.P. *J. Organomet. Chem.* **1976**, *121*, 19.

¹⁶For a monograph, see Sokolov, V.I. *Chirality and Optical Activity in Organometallic Compounds*, Gordon and Breach, NY, **1990**.

¹⁷Organomercury compounds were first resolved by three groups: Jensen, F.R.; Whipple, L.D.; Wedegaertner, D.K.; Landgrebe, J.A. *J. Am. Chem. Soc.* **1959**, *81*, 1262; Charman, H.B.; Hughes, E.D.; Ingold, C.K. *J. Chem. Soc.* **1959**, 2523, 2530; Reutov, O.A.; Uglova, E.V. *Bull. Acad. Sci. USSR Div. Chem. Sci.* **1959**, 735.

¹⁸This was done first by Walborsky, H.M.; Young, A.E. *J. Am. Chem. Soc.* **1964**, *86*, 3288.

¹⁹Jensen, F.R.; Nakamaye, K.L. *J. Am. Chem. Soc.* **1966**, *88*, 3437.

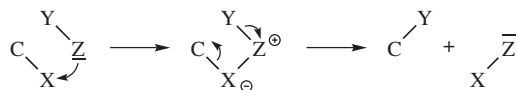

prevents reaction on the frontside and when the electrophile does not carry a Z group (p. 754).

The S_E2 (back) mechanism can therefore be identified in certain cases (if inversion of configuration is found), but it is plain that stereochemical investigations cannot distinguish between the S_E2 (front) and the S_Ei mechanisms and that, in the many cases where configurationally stable substrates cannot be prepared, such investigations are of no help at all in distinguishing among all three of the second-order mechanisms. Unfortunately, there are not many other methods that lead to unequivocal conclusions. One method that has been used in an attempt to distinguish between the S_Ei mechanism on the one hand and the S_E2 pathways on the other involves the study of salt effects on the rate. It may be recalled (p. 501) that reactions in which neutral starting molecules acquire charges in the transition state are aided by an increasing concentration of added ions. Thus the S_Ei mechanism would be less influenced by salt effects than would either of the S_E2 mechanisms. On this basis, Abraham and co-workers²⁰ concluded that the reactions $R_4Sn + HgX_2 \rightarrow RHgX + R_3SnX$ (X = Cl or I) take place by S_E2 and not by S_Ei mechanisms. Similar investigations involve changes in solvent polarity (see also, p. 765).²¹ In the case of the reaction

(where $R = R' = iPr$ and $R = iPr$, $R' = neopentyl$), the use of polar solvents gave predominant inversion, while nonpolar solvents gave predominant retention.²²

On the basis of evidence from reactivity studies, it has been suggested²³ that a variation of the S_Ei mechanism is possible in which the group Z becomes attached to X before the latter becomes detached:

This process has been called the S_EC²² or S_E2 (co-ord)²⁴ mechanism (IUPAC designation $A_n + cyclo\text{-}D_EA_E D_n$).

It has been shown that in certain cases (e.g., $Me_4Sn + I_2$) the reactants in an S_E2 reaction, when mixed, give rise to an immediate charge-transfer spectrum (p. 115), showing that an electron donor-acceptor (EDA) complex has been formed.²⁵ In these cases it is likely that the EDA complex is an intermediate in the reaction.

THE S_E1 MECHANISM

The S_E1 mechanism is analogous to the S_N1. It involves two steps: a slow ionization and a fast combination.

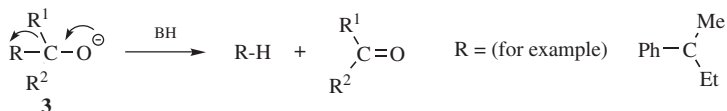

The IUPAC designation is D_E + A_E. First-order kinetics are predicted and many such examples have been found. Other evidence for the S_E1 mechanism was obtained in a study of base-catalyzed tautomerization. In the reaction

the rate of deuterium exchange was the same as the rate of racemization²⁶ and there was an isotope effect.²⁷

The S_N1 reactions do not proceed at strained bridgehead carbons (e.g., in [2.2.1] bicyclic systems, p. 435) because planar carbocations cannot form at these carbons. However, carbanions not stabilized by resonance are probably not planar, and S_E1 reactions readily occur with this type of substrate. Indeed, the question of carbanion structure is intimately tied into the problem of the stereochemistry of the S_E1 reaction. If a carbanion is planar, racemization should occur. If it is pyramidal and *can hold its structure*, the result should be retention of configuration. On the other hand, even a pyramidal carbanion will give racemization if it cannot hold its structure, that is, if there is pyramidal inversion as with amines (p. 142). Unfortunately, the only carbanions that can be studied easily are those stabilized by resonance, which makes them planar, as expected (p. 258). For simple alkyl carbanions, the main approach to determining structure has been to study the stereochemistry of S_E1 reactions rather than the other way around. Racemization is almost always observed, but whether this is caused by planar carbanions or by oscillating pyramidal carbanions is not known. In either case racemization occurs whenever a carbanion is completely free or is symmetrically solvated.

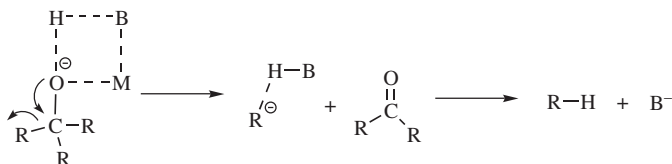

However, even planar carbanions need not give racemization. Cram found that retention and even inversion can occur in the alkoxide (see **3**) cleavage reaction (**12-41**):

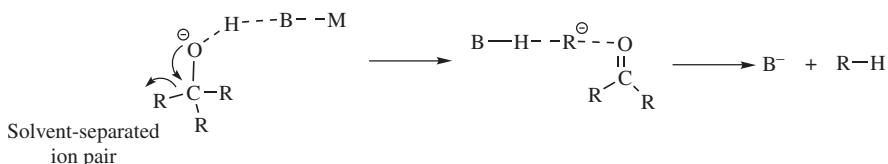

²⁶Hsu, S.K.; Ingold, C.K.; Wilson, C.L. *J. Chem. Soc.* **1938**, 78.

²⁷Wilson, C.L. *J. Chem. Soc.* **1936**, 1550.

which is a first-order S_E1 reaction involving resonance-stabilized planar carbanions (here designated R⁻).²⁸ By changing the solvent Cram was able to produce products ranging from 99% retention to 60% inversion and including complete racemization. These results are explained by a carbanion that is not completely free but is solvated. In nondissociating, nonpolar solvents, such as benzene or dioxane, the alkoxide ion exists as an ion pair, solvated by the solvent BH:

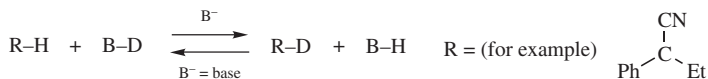

In the course of the cleavage, the proton of the solvent moves in to solvate the newly forming carbanion. As is easily seen, this solvation is asymmetrical since the solvent molecule is already on the front side of the carbanion. When the carbanion actually bonds with the proton, the result is retention of the original configuration. In protic solvents, such as diethylene glycol, a good deal of inversion is found. In these solvents, the *leaving group* solvates the carbanion, so the solvent can solvate it only from the opposite side:

When C–H bond formation occurs, the result is inversion. Racemization results in polar aprotic solvents, such as DMSO. In these solvents, the carbanions are relatively long lived (because the solvent has no proton to donate) and symmetrically solvated.

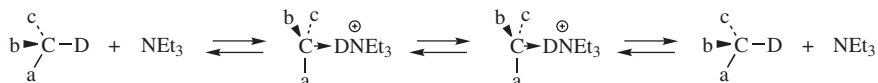

Similar behavior was found for carbanions generated by base-catalyzed hydrogen exchange (reaction 12-1):²⁹

²⁸See Cram, D.J.; Langemann, A.; Allinger, J.; Kopecky, K.R. *J. Am. Chem. Soc.* **1959**, *81*, 5740; Hoffman, T.D.; Cram, D.J. *J. Am. Chem. Soc.* **1969**, *91*, 1009. For a discussion, see Cram, D.J. *Fundamentals of Carbanion Chemistry*, Academic Press, NY, **1965**, pp. 138–158.

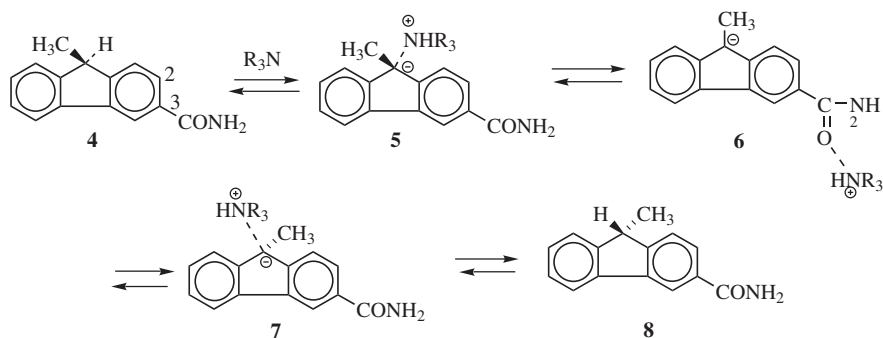

²⁹See Roitman, J.N.; Cram, D.J. *J. Am. Chem. Soc.* **1971**, *93*, 2225, 2231 and references cited therein; Cram, J.M.; Cram, D.J. *Intra-Sci. Chem. Rep.* **1973**, *7*(3), 1. For a discussion, see Cram, D.J. *Fundamentals of Carbanion Chemistry*, Academic Press, NY, **1965**, pp. 85–105.

In this case, information was obtained from measurement of the ratio of k_e (rate constant for isotopic exchange) to k_a (rate constant for racemization). A k_e/k_a ratio substantially >1 means retention of configuration, since many individual isotopic exchanges are not producing a change in configuration. A k_e/k_a ratio of ~ 1 indicates racemization and a ratio of $\frac{1}{2}$ corresponds to inversion (see p. 430). All three types of steric behavior were found, depending on R, the base, and the solvent. As with the alkoxide cleavage reaction, retention was generally found in solvents of low dielectric constant, racemization in polar aprotic solvents, and inversion in protic solvents. However, in the proton-exchange reactions, a fourth type of behavior was encountered. In aprotic solvents, with aprotic bases like tertiary amines, the k_e/k_a ratio was found to be *less* than 0.5, indicating that racemization took place *faster* than isotopic exchange (this process is known as *isoracemization*). Under these conditions, the conjugate acid of the amine remains associated with the carbanion as an ion pair. Occasionally, the ion pair dissociates long enough for the carbanion to turn over and recapture the proton:

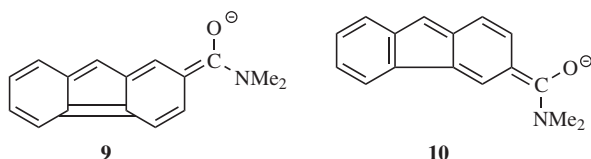

Thus, inversion (and hence racemization, which is produced by repeated acts of inversion) occurs without exchange. A single act of inversion without exchange is called *isoinversion*.

The isoinversion process can take place by a pathway in which a positive species migrates in a stepwise fashion around a molecule from one nucleophilic position to another. For example, in the exchange reaction of 3-carboxamido-9-methylfluorene (**4**) with Pr_3N in *t*-BuOH, it has been proposed that the amine removes

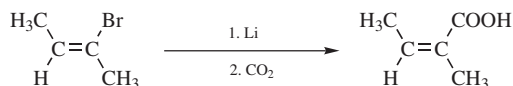

a proton from the 9 position of **4** and conducts the proton out to the C=O oxygen (**6**), around the molecule, and back to C-9 on the opposite face of the anion. Collapse of **7** gives the inverted product **8**. Of course, **6** could also go back to **4**, but a molecule that undergoes the total process $\mathbf{4} \rightarrow \mathbf{5} \rightarrow \mathbf{6} \rightarrow \mathbf{7} \rightarrow \mathbf{8}$ has experienced an inversion without an exchange. Evidence for this pathway, called the *conducted*

tour mechanism,³⁰ is that the 12-carboxamido isomer of **4** does not give isoracemization. In this case, the negative charge on the oxygen atom in the anion corresponding to **6** is less, because a canonical form in which oxygen acquires a full negative charge (**9**) results in disruption of the aromatic sextet in both

benzene rings (cf. **10** where one benzene ring is intact). Whether the isoracemization process takes place by the conducted tour mechanism or a simple nonstructured contact ion-pair mechanism depends on the nature of the substrate (e.g., a proper functional group is necessary for the conducted tour mechanism) and of the base.³¹

It is known that vinylic carbanions *can* maintain configuration, so that S_E1 mechanisms should produce retention there. This has been found to be the case. For example, *trans*-2-bromo-2-butene was converted to 64–74% angelic acid:³²

Only ~5% of the *cis* isomer, tiglic acid, was produced. In addition, certain carbanions in which the negative charge is stabilized by *d*-orbital overlap can maintain configuration (p. 258) and S_E1 reactions involving them proceed with retention of configuration.

Electrophilic Substitution Accompanied by Double-Bond Shifts

When electrophilic substitution is carried out at an allylic substrate, the product may be rearranged (**11** → **12**). This type of process is analogous to the nucleophilic

³²Dreiding, A.S.; Pratt, R.J. *J. Am. Chem. Soc.* **1954**, *76*, 1902. See also Walborsky, H.M.; Turner, L.M. *J. Am. Chem. Soc.* **1972**, *94*, 2273.

allylic rearrangements discussed in Chapter 10 (p. 468). There are two principal pathways. The first of these is analogous to the S_E1 mechanism in that the leaving group is first removed, giving a resonance-stabilized allylic carbanion, which then attacks the electrophile.

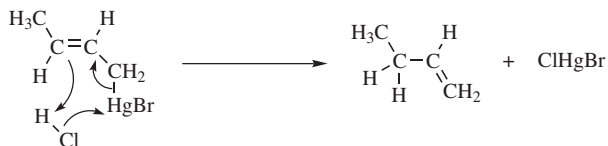

In the other pathway, the Y group is first attacked by the π -bond, giving a carbocation, which then loses X with formation of the alkene unit.

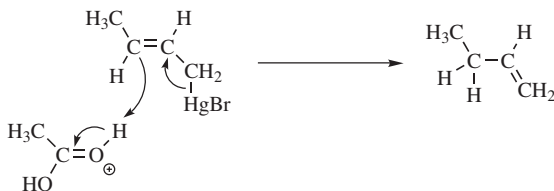

These mechanisms are more fully discussed under reaction **12-2**.

Most electrophilic allylic rearrangements involve loss of hydrogen, but they have also been observed with metallic leaving groups.³³ Sleezer, Winstein, and Young found that crotylmercuric bromide reacted with HCl $\sim 10^7$ times faster than *n*-butylmercuric bromide and the product was $>99\%$ 1-butene.³⁴ These facts point to an S_{Ei}' mechanism (IUPAC designation *cyclo-1/3/D_EA_ED_nA_n*):

The reaction of the same compound with acetic acid-perchloric acid seems to proceed by an S_{E2}' mechanism (IUPAC designation *1/3/D_EA_E*):³⁴

³³For a review of reactions of allylic organometallic compounds, see Courtois, G.; Miginiac, L. *J. Organomet. Chem.* **1974**, *69*, 1.

Perkin Trans. 1* **1975**, 2140; Kashin, A.N.; Bakunin, V.N.; Khutoryanskii, V.A.; Beletskaya, I.P.; Reutov, O.A. *J. Org. Chem. USSR* **1979**, *15*, 12; *J. Organomet. Chem.* **1979**, *171*, 309.

The geometry of electrophilic allylic rearrangement has not been studied very much (cf. the nucleophilic case, p. 471), but in most cases the rearrangement takes place with anti stereoselectivity,³⁵ although syn stereoselectivity has also been demonstrated.³⁶ In one case, use of the electrophile H^+ and the leaving group $SnMe_3$ gave both syn and anti stereoselectivity, depending on whether the substrate was cis or trans.³⁷

Other Mechanisms

Addition–elimination (12-16) and cyclic mechanisms (12-40) are also known.

Much less work has been done on electrophilic aliphatic substitution mechanisms than on nucleophilic substitutions, and the exact mechanisms of many of the reactions in this chapter are in doubt. For many of them, not enough work has been done to permit us to decide which of the mechanisms described in this chapter is operating, if indeed any is. There may be other electrophilic substitution mechanisms, and some of the reactions in this chapter may not even be electrophilic substitutions at all.

REACTIVITY

Only a small amount of work has been done in this area, compared to the vast amount done for aliphatic nucleophilic substitution and aromatic electrophilic substitution. Only a few conclusions, most of them sketchy or tentative, can be drawn.³⁸

1. *Effect of Substrate.* For S_E1 reactions electron-donating groups decrease rates and electron-withdrawing groups increase them. This is as would be expected from a reaction in which the rate-determining step is analogous to the cleavage of a proton from an acid. For the S_E2 (back) mechanism, Jensen and Davis¹² showed that the reactivity of alkyl groups is similar to that for the S_N2 mechanism (i.e., $Me > Et > Pr > iPr > neopentyl$), as would be expected, since both involve backside attack and both are equally affected by steric hindrance. In fact, this pattern of reactivity can be regarded as evidence for the occurrence of the S_E2 (back) mechanism in cases where

TABLE 12.1. Relative Rates of the Reaction of RHgBr with Br₂ and Br⁻ ⁴¹

R	Relative Rate	R	Relative Rate
Me	1	Et	10.8
Et	10.8	<i>i</i> Bu	1.24
<i>i</i> Pr	780	Neopentyl	0.173
<i>t</i> -Bu	3370		

stereochemical investigation is not feasible.³⁹ For S_E2 reactions that proceed with retention, several studies have been made with varying results, depending on the reaction.⁴⁰ One such study, which examined the reaction RHgBr + Br₂ → RBr catalyzed by Br⁻, gave the results shown in Table 12.1.⁴¹ As can be seen, a branching increased the rates, while β branching decreased them. Sayre and Jensen attributed the decreased rates to steric hindrance, although attack here was definitely frontside, and the increased rates to the electron-donating effect of the alkyl groups, which stabilized the electron-deficient transition state.⁴² Of course, steric hindrance should also be present with the a branched groups, so these workers concluded that if it were not, the rates would be even greater. The Br electrophile is a rather large one and it is likely that smaller steric effects are present with smaller electrophiles. The rates of certain second-order substitutions of organotin compounds have been found to increase with increasing electron withdrawal by substituents. This behavior has been ascribed⁴³ to an S_E2 mechanism involving ion pairs, analogous to S_N2 ion-pair mechanism for nucleophilic substitution (p. 441). Solvolysis of 2-bromo-1,1,1-trifluoro-2-(*p*-methoxyphenyl)ethane in water proceeds via a free carbocation intermediate, but ion pairing influences the reaction in the presence of bromide ion.⁴⁴

2. *Effect of Leaving Group.* For both S_E1 and second-order mechanisms, the more polar the C–X bond, the easier it is for the electrofuge to cleave. For metallic leaving groups in which the metal has a valence >1, the nature of the other group or groups attached to the metal thus has an effect on the reaction.

³⁹Another method involves measurement of the susceptibility of the rate to increased pressure: See Isaacs, N.S.; Javaid, K. *Tetrahedron Lett.* **1977**, 3073; Isaacs, N.S.; Laila, A.H. *Tetrahedron Lett.* **1984**, 25, 2407.

⁴⁰For some of these, see Abraham, M.H.; Grellier, P.L. *J. Chem. Soc. Perkin Trans. 2* **1973**, 1132; Dessy, R.E.; Reynolds, G.F.; Kim, J. *J. Am. Chem. Soc.* **1959**, 81, 2683; Minato, H.; Ware, J.C.; Traylor, T.G. *J. Am. Chem. Soc.* **1963**, 85, 3024; Boué, S.; Gielen, M.; Nasielski, J. *J. Organomet. Chem.* **1967**, 9, 443; Abraham, M.H.; Broadhurst, A.T.; Clark, I.D.; Koenigsberger, R.U.; Dadjour, D.F. *J. Organomet. Chem.* **1981**, 209, 37.

⁴¹Sayre, L.M.; Jensen, F.R. *J. Am. Chem. Soc.* **1979**, 101, 6001.

⁴²A similar conclusion, that steric and electronic effects are both present, was reached for a different system by Nugent, W.A.; Kochi, J.K. *J. Am. Chem. Soc.* **1976**, 98, 5979.

⁴³Reutov, O.A. *J. Organomet. Chem.* **1983**, 250, 145. See also, Butin, K.P.; Magdesieva, T.V. *J. Organomet. Chem.* **1985**, 292, 47; Beletskaya, I.P. *Sov. Sci. Rev. Sect. B* **1979**, 1, 119.

⁴⁴Richard, J.P. *J. Org. Chem.* **1992**, 57, 625.

For example, consider a series of organomercurials RHgW . Because a more electronegative W decreases the polarity of the C-Hg bond and furthermore results in a less stable HgW^+ , the electrofugal ability of HgW decreases with increasing electronegativity of W . Thus, HgR' (from RHgR') is a better leaving group than HgCl (from RHgCl). Also in accord with this is the leaving-group order $\text{Hg-}t\text{-Bu} > \text{Hg-}i\text{Pr} > \text{HgEt} > \text{HgMe}$, reported for acetoxylation of R_2Hg ,⁴² since the more highly branched alkyl groups better help to spread the positive charge. It might be expected that, when metals are the leaving groups, $\text{S}_{\text{E}1}$ mechanisms would be favored, while with carbon leaving groups, second-order mechanisms would be found. However, the results so far reported have been just about the reverse of this. For carbon leaving groups the mechanism is usually $\text{S}_{\text{E}1}$, while for metallic leaving groups the mechanism is almost always $\text{S}_{\text{E}2}$ or $\text{S}_{\text{E}i}$. A number of reports of $\text{S}_{\text{E}1}$ reactions with metallic leaving groups have appeared,⁴⁵ but the mechanism is not easy to prove and many of these reports have been challenged.⁴⁶ Reutov and co-workers⁴⁵ have expressed the view that in such reactions a nucleophile (which may be the solvent) must assist in the removal of the electrofuge and refer to such processes as $\text{S}_{\text{E}1(\text{N})}$ reactions.

3. *Effect of Solvent.*⁴⁷ In addition to the solvent effects on certain $\text{S}_{\text{E}1}$ reactions, mentioned earlier (p. 758), solvents can influence the mechanism that is preferred. As with nucleophilic substitution (p. 501), an increase in solvent polarity increases the possibility of an ionizing mechanism, in this case $\text{S}_{\text{E}1}$, in comparison with the second-order mechanisms, which do not involve ions. As previously mentioned (p. 758), the solvent can also exert an influence between the $\text{S}_{\text{E}2}$ (front or back) and $\text{S}_{\text{E}i}$ mechanisms in that the rates of $\text{S}_{\text{E}2}$ mechanisms should be increased by an increase in solvent polarity, while $\text{S}_{\text{E}i}$ mechanisms are much less affected.

REACTIONS

The reactions in this chapter are arranged in order of leaving group: hydrogen, metals, halogen, and carbon. Electrophilic substitutions at a nitrogen atom are treated last.

Hydrogen as Leaving Group

A. Hydrogen as the Electrophile

12-1 Hydrogen Exchange

Deuterio-de-hydrogenation or Deuteriation

Hydrogen exchange can be accomplished by treatment with acids or bases. As with **11-1**, the exchange reaction is mostly used to study mechanistic questions, such as relative acidities, but it can be used synthetically to prepare deuterated or tritiated molecules. When ordinary strong acids, such as H_2SO_4 are used, only fairly acidic protons n carbon exchange, for example, acetylenic and allylic. However, primary, secondary, and tertiary hydrogens of alkanes can be exchanged by treatment with superacids (p. 236).⁴⁸ The order of hydrogen reactivity is tertiary > secondary > primary. Where C–C bonds are present, they may be cleaved also (**12-47**). The mechanism of the exchange (illustrated for methane) has been formulated as involving attack of H^+ on the C–H bond to give the pentavalent methanium ion that loses H_2 to give a tervalent

carbocation.⁴⁹ The methanium ion CH_5^+ has a three-center, two-electron bond.⁵⁰ It is not known whether the methanium ion is a transition state or a true intermediate, but an ion CH_5^+ has been detected in the mass spectrum.⁵¹ The IR spectrum of the ethanium ion C_2H_7^+ has been measured in the gas phase.⁵² Note that the two electrons in the three-center, two-electron bond can move in three directions, in accord with the threefold symmetry of such a structure. The electrons can move to unite the two hydrogens, leaving the CH_3^+ free (the forward reaction), or they can unite the CH_3 with either of the two hydrogens, leaving the other hydrogen as a free H^+ ion (the reverse reaction). Actually, the methyl cation is not stable under these conditions. It can go back to CH_4 by the route shown (leading to H^+ exchange) or it can react with additional CH_4 molecules (**12-20**) to eventually yield the *tert*-butyl cation, which is stable in these superacid solutions. Hydride ion can also be removed from alkanes (producing tervalent carbocations) by treatment with pure SbF_5 in the absence of any source of H^+ .⁵³ Complete or almost complete perdeuteriation of cyclic alkenes has been achieved by treatment with dilute $\text{DCl}/\text{D}_2\text{O}$ in sealed Pyrex tubes at $165\text{--}280^\circ\text{C}$.⁵⁴

⁴⁸For reviews, see Olah, G.A.; Prakash, G.K.S.; Sommer, J. *Superacids*, Wiley, NY, **1985**, pp. 244–249; Olah, G.A. *Angew. Chem. Int. Ed.* **1973**, *12*, 173; Brouwer, D.M.; Hogeveen, H. *Prog. Phys. Org. Chem.* **1972**, *9*, 179, 180–203.

⁴⁹The mechanism may not be this simple in all cases. For discussions, see McMurry, J.E.; Lectka, T. *J. Am. Chem. Soc.* **1990**, *112*, 869; Culmann, J.; Sommer, J. *J. Am. Chem. Soc.* **1990**, *112*, 4057.

Exchange with bases involves an S_E1 mechanism.

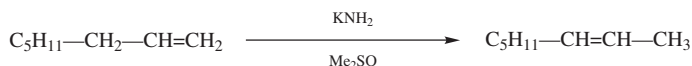

Of course, such exchange is most successful for relatively acidic protons, such as those α to a carbonyl group, but even weakly acidic protons can exchange with bases if the bases are strong enough (see p. 251).

Alkanes and cycloalkanes, of both low and high molecular weight, can be fully perdeuterated treatment with D₂ gas and a catalyst, such as Rh, Pt, or Pd.⁵⁵

OS VI, 432.

12-2 Migration of Double Bonds

3/Hydro-de-hydrogenation

The double bonds of many unsaturated compounds are shifted⁵⁶ on treatment with strong bases.⁵⁷ In many cases, equilibrium mixtures are obtained and the thermodynamically most stable isomer predominates.⁵⁸ Thus, if the new double bond can be in conjugation with one already present or with an aromatic ring, the migration favors the conjugated compound.⁵⁹ If the choice is between an exocyclic and an endocyclic double bond (particularly with six-membered rings), it generally chooses the latter. In the absence of considerations like these, Zaitsev's rule (p. 1497) applies and the double bond goes to the carbon with the fewest hydrogens. All these considerations lead us to predict that terminal alkenes can be isomerized to internal ones, nonconjugated alkenes to conjugated, exo six-membered-ring alkenes to endo, and so on, and not the other way around. This is indeed usually the case.

⁵⁵See, for example, Atkinson, J.G.; Luke, M.O.; Stuart, R.S. *Can. J. Chem.* **1967**, *45*, 1511.

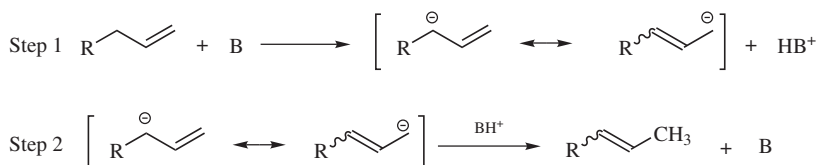

⁵⁶For a list of methods used to shift double and triple bonds, with references, see Larock, R.C. *Comprehensive Organic Transformations*, 2nd ed., Wiley-VCH, NY, **1999**, pp. 220–226, 567–568.

⁵⁹For a review of conversions of β,γ enones to α,β enones, see Pollack, R.M.; Bounds, P.L.; Bevins, C.L., in Patai, S.; Rappoport, Z. *The Chemistry of Enones*, pt. 1, Wiley, NY, **1989**, pp. 559–597.

This reaction, for which the term *prototropic rearrangement* is sometimes used, is an example of electrophilic substitution with accompanying allylic rearrangement. The mechanism involves abstraction by a base to give a resonance-stabilized carbanion, which then combines with a proton at the position that will give the more stable alkene:⁶⁰

This mechanism is exactly analogous to the allylic-rearrangement mechanism for nucleophilic substitution (p. 468). UV spectra of allylbenzene and 1-propenylbenzene in solutions containing NH_2^- are identical, which shows that the same carbanion is present in both cases, as required by this mechanism.⁶¹ The acid BH^+ protonates the position that will give the more stable product, although the ratio of the two possible products can vary with the identity of BH^+ .⁶² It has been shown that base-catalyzed double-bond shifts are partially intramolecular, at least in some cases.⁶³ The intramolecular nature has been ascribed to a *conducted tour mechanism* (p. 761) in which the base leads the proton from one carbanionic site to the other (**13** \rightarrow **14**).⁶⁴

Triple bonds can also migrate in the presence of bases,⁶⁵ but through the allene intermediate:⁶⁶

⁶⁶For a review of rearrangements involving allenes, see Huntsman, W.D., in Patai, S. *The Chemistry of Ketenes, Allenes, and Related Compounds*, pt. 2; Wiley, NY, **1980**, pp. 521–667.

In general, strong bases, for example, NaNH_2 , convert internal alkynes to terminal alkynes (a particularly good base for this purpose is potassium 3-aminopropylamide $\text{NH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NHHK}^{67}$), because the equilibrium is shifted by formation of the acetylid ion. With weaker bases such as NaOH (which are not strong enough to remove the acetylenic proton), the internal alkynes are favored because of their greater thermodynamic stability. In some cases the reaction can be stopped at the allene stage.⁶⁸ The reaction then becomes a method for the preparation of allenes.⁶⁹ The reaction of propargylic alcohols with tosylhydrazine, PPh_3 , and DEAD also generates allenes.⁷⁰

Double-bond rearrangements can also take place on treatment with acids. Both proton and Lewis⁷¹ acids can be used. The mechanism in the case of proton acids is the reverse of the previous one; first a proton is gained, giving a carbocation, and then another is lost:

As in the case of the base-catalyzed reaction, the thermodynamically most stable alkene is the one predominantly formed. However, the acid-catalyzed reaction is much less synthetically useful because carbocations give rise to many side products. If the substrate has several possible locations for a double bond, mixtures of all possible isomers are usually obtained. Isomerization of 1-decene, for example, gives a mixture that contains not only 1-decene and *cis*- and *trans*-2-decene, but also the *cis* and *trans* isomers of 3-, 4-, and 5-decene as well as branched alkenes resulting from rearrangement of carbocations. It is true that the most stable alkenes predominate, but many of them have stabilities that are close together. Acid-catalyzed migration of triple bonds (with allene intermediates) can be accomplished if very strong acids (e.g., HF—PF_5) are used.⁷² If the mechanism is the same as that for double bonds, vinyl cations are intermediates.

Double-bond isomerization can also take place in other ways. Nucleophilic allylic rearrangements were discussed in Chapter 10 (p. 468). Electrocyclic and sigmatropic rearrangements are treated at **18-27–18-35**. Double-bond migrations have also been accomplished photochemically,⁷³ and by means of metallic ion (most

⁷³Schönberg, A. *Preparative Organic Photochemistry*, Springer, NY, **1968**, pp. 22–24.

often complex ions containing Pt, Rh, or Ru) or metal carbonyl catalysts.⁷⁴ In the latter case, there are at least two possible mechanisms. One of these, which requires external hydrogen, is called the *metal hydride addition–elimination mechanism*:

The other mechanism, called the *π -allyl complex mechanism*, does not require external hydrogen and proceeds by hydrogen abstraction to form the η^3 - π -allyl complex **15** (see p. 117 and 10-60).

Another difference between the two mechanisms is that the former involves 1,2- and the latter 1,3-shifts. The isomerization of 1-butene by rhodium(I) is an example of a reaction that takes place by the metal hydride mechanism,⁷⁵ while an example of the π -allyl complex mechanism is found in the $\text{Fe}_3(\text{CO})_{12}$ -catalyzed isomerization of 3-ethyl-1-pentene.⁷⁶ A palladium catalyst was used to convert alkynones $\text{RCOC}\equiv\text{CCH}_2\text{CH}_2\text{R}'$ to 2,4-alkadien-1-ones, $\text{RCOCH}=\text{CHCH}=\text{CHCHR}'$.⁷⁷ The reaction of an en-yne with HSiCl_3 and a palladium catalyst generated an allene with moderate enantioselectivity (see p 148 for chiral allenes).⁷⁸

The metal catalysis method has been used for the preparation of simple enols, by isomerization of allylic alcohols, for example,⁷⁹ these enols are stable enough for isolation (see p. 231), but slowly tautomerize to the aldehyde or ketone, with half-lives ranging from 40 to 50 min to several days.⁷⁹

No matter which of the electrophilic methods of double-bond shifting is employed, the thermodynamically most stable alkene is usually formed in the largest amount in most cases, although a few anomalies are known. However, an indirect method of double-bond isomerization is known, leading to migration in the other direction. This involves conversion of the alkene to a borane (**15-16**), rearrangement of the borane (**18-11**), oxidation and hydrolysis of the newly formed borane to the alcohol **17** (see **12-31**), and dehydration of the alcohol (**17-1**) to the alkene. The reaction is driven by the fact that with heating the addition of borane is reversible, and the equilibrium favors formation of the less sterically hindered borane, which is **16** in this case.

Since the migration reaction is always toward the end of a chain, terminal alkenes can be produced from internal ones, so the migration is often opposite to that with the other methods. Alternatively, the rearranged borane can be converted directly to the alkene by heating with an alkene of molecular weight higher than that of the product (**17-15**). Photochemical isomerization can also lead to the thermodynamically less stable isomer.⁸⁰

If a hydroxy group is present in the chain, *it* may lose a proton, so that a ketone is the product, for example,⁸¹

Similarly, α -hydroxy triple-bond compounds have given α,β -unsaturated ketones.⁸²

12-3 Keto–Enol Tautomerization

3/O-Hydro-de-hydrogenation

The tautomeric equilibrium between enols and ketones or aldehydes (keto–enol tautomerism) is a form of prototropy,⁸³ but is not normally a preparative reaction. For some ketones, however, both forms can be prepared (see p. 101 for a discussion of this and other aspects of tautomerism). Keto–enol tautomerism occurs in systems containing one or more carbonyl groups linked to sp^3 carbons bearing one or more hydrogen atoms. The keto tautomer is generally more stable than the enol tautomer for neutral systems, and for most ketones and aldehydes only the keto form is detectable under ordinary conditions. The availability of additional intramolecular stabilization through hydrogen bonding or complete electron delocalization (as in phenol), may cause the enol tautomer to be favored.

Keto–enol tautomerism cannot take place without at least a trace of acid or base,⁸⁴ since the acidic or basic center or both in the tautomeric substance is too weak.⁸⁵ In this equilibrium, the heteroatom is the basic site the proton is the acidic site. For tautomerism in general (see p 98),⁸⁶ the presence of an acid or a base is not necessary to initiate the isomerization since each tautomeric substance possesses amphiprotic properties.⁸⁵ Keto-enol tautomerism is therefore the exception.

Polar protic solvents, such as water or alcohol, may participate in the proton transfer by forming a cyclic or a linear complex with the tautomers.⁸⁷ Whether the complex formed is cyclic or linear depends on the conformation and configuration of the tautomers. In a strongly polar aprotic solvent and in the presence of an acid or a base, the tautomeric molecule may lose or gain a proton and form the corresponding mesomeric anion or cation, which, in turn, may gain or lose a proton, respectively, and yield a new tautomeric form.⁸⁸ The structural features of the carbonyl compound influences the equilibrium.⁸⁹ There is a rate acceleration when $\text{LiN}(\text{SiMe}_3)_2\text{-NEt}_3$ is used.⁹⁰ It has been shown that ring strain plays no significant role on the rate of base-catalyzed enolization.⁹¹ Differing conjugative stabilization by $\text{CH}-\pi$ orbital overlap does not directly influence stereoselectivity, and steric effects are generally not large enough to cause the several kcal/mol energy difference seen between transition structures unless there is exceptional crowding.⁹² It is noted that sterically stabilized enols are known,⁹³ including arylacetaldehydes.⁹⁴ Torsional strain involving vicinal bonds does contribute significantly to stereoselectivity in enolate formation.⁹²

The acid and base catalyzed mechanisms are identical to those in 12-2.⁹⁵

Acid-catalyzed

Base-catalyzed⁹⁶

For each catalyst, the mechanism for one direction is the exact reverse of the other, by the principle of microscopic reversibility.⁹⁷ As expected from mechanisms in which the C–H bond is broken in the rate-determining step, substrates of the type RCD_2COR show deuterium isotope effects (of ~ 5) in both the basic⁹⁸ and the acid⁹⁹-catalyzed processes. The keto–enol/enolate anion equilibrium has been studied in terms of the influence of β -oxygen¹⁰⁰ or β -nitrogen¹⁰¹ substituents.

Although the conversion of an aldehyde or a ketone to its enol tautomer is not generally a preparative procedure, the reactions do have their preparative aspects. If a full equivalent of base per equivalent of ketone is used, the enolate ion (**18**) is formed and can be isolated¹⁰² (see, e.g., the alkylation reaction in **10-68**).¹⁰³ When enol ethers or esters are hydrolyzed, the enols initially formed immediately tautomerize to the aldehydes or ketones. In addition, the overall processes (forward plus reverse reactions) are often used for equilibration purposes. When an optically active compound in which the chirality is due to a stereogenic carbon α to a carbonyl group (as in **19**) is treated with acid or base, racemization results.¹⁰⁴

⁹⁶Another mechanism for base-catalyzed enolization has been reported when the base is a tertiary amine: See Bruce, P.Y. *J. Am. Chem. Soc.* **1983**, *105*, 4982; **1989**, *111*, 962; **1990**, *112*, 7361.

⁹⁷It has been proposed that the acid-catalyzed ketonization of simple enols is concerted; that is, both of the processes shown in the equation take place simultaneously. This would mean that in these cases the forward reaction is also concerted. For evidence in favor of this proposal, see Capon, B.; Siddhanta, A.K.; Zucco, C. *J. Org. Chem.* **1985**, *50*, 3580. For evidence against it, see Chiang, Y.; Hojatti, M.; Keeffe, J.R.; Kresge, A.J.; Schepp, N.P.; Wirz, J. **1987**, *109*, 4000 and references cited therein.

If there is another

stereogenic center in the molecule, the less stable epimer can be converted to the more stable one in this manner, and this is often done. For example, *cis*-decalone can be equilibrated to the *trans* isomer. Isotopic exchange can also be accomplished at the a position of an aldehyde or ketone in a similar manner. The role of additives, such as ZnCl_2 on the stereogenic enolization reactions using chiral cases has been discussed.¹⁰⁵ Enantioselective enolate anion protonation reactions have been studied.¹⁰⁶ For the acid-catalyzed process, exchange or equilibration is accomplished only if the carbonyl compound is completely converted to the enol and then back, but in the base-catalyzed process exchange or equilibration can take place if only the first step (conversion to the enolate ion) takes place. The difference is usually academic. In cyclic compounds, *cis*- to *trans*-isomerization can occur via the enol.¹⁰⁷

In the case of the ketone **20**, a racemic mixture was converted to an optically active mixture (optical yield 46%) by treatment with the chiral base **21**.¹⁰⁸ This happened because **21** reacted with one enantiomer of **20** faster than with the other (an example of kinetic resolution). The enolate **22** must remain coordinated with the chiral amine, and it is the amine that reprotonate **22**, not an added proton donor.

Enolizable hydrogens can be replaced by deuterium (and ^{16}O by ^{18}O) by passage of a sample through a deuterated (or ^{18}O -containing) gas-chromatography column.¹⁰⁹

There are many enol-keto interconversions and acidification reactions of enolate ions to the keto forms listed in *Organic Syntheses*. No attempt is made to list them here.

B. Halogen Electrophiles

Halogenation of unactivated hydrocarbons is discussed in **14-1**.

12-4 Halogenation of Aldehydes and Ketones

Halogenation or Halo-de-hydrogenation

Aldehydes and ketones can be halogenated in the α position with bromine, chlorine, or iodine.¹¹⁰ The reaction is not successful with fluorine.¹¹¹ Sulfuryl chloride,¹¹² $\text{NaClO}_2/\text{Mn}(\text{acac})_3$,¹¹³ $\text{Me}_3\text{SiCl}-\text{Me}_2\text{SO}$,¹¹⁴ $\text{Me}_3\text{SiCl}-\text{MnO}_2$,¹¹⁵ and cupric chloride¹¹⁶ have been used as reagents for chlorination, and *N*-bromosuccinimide (see **14-3**),¹¹⁷ *t*-BuBr-DMSO,¹¹⁸ $\text{Me}_3\text{SiBr}-\text{DMSO}$,¹¹⁹ tetrabutylammonium tribromide,¹²⁰ and bromine•dioxane on silica with microwave irradiation¹²¹ for bromination. Bromination of methyl ketones was done using PhI(OH)OTs with microwave irradiation, followed by treatment with MgBr_2 and microwave irradiation.¹²² α -Chloro aldehydes are formed with Cl_2 and a catalytic amount of tetraethylammonium chloride.¹²³ Chlorination of aldehydes with good enantioselectivity was

reported using a chlorinated quinone and L-proline, with the reaction proceeding via the chiral enamine.¹²⁴ Iodination has been accomplished with I₂-HgCl₂,¹²⁵ with I₂-cerium(IV) ammonium nitrate,¹²⁶ and with iodine using 1-chloromethyl-4-fluoro-1,4-diazoniabicyclo[2.2.2]octane bis(tetrafluoroborate), known as Selectfluor F-TEDA-BF₄, in methanol.¹²⁷ Treatment of a ketone with (hydroxy-*p*-nitrobenzenesulfonyloxy)benzene followed by SmI₂ give the α -iodo ketone.¹²⁸ Methyl ketones react with *N*-iodosuccinimide (NIS) and tosic acid with microwave irradiation without solvent to give the α -iodo ketone.¹²⁹ Several methods have been reported for the preparation of α -fluoro aldehydes and ketones.¹³⁰ Another Selectfluor, 1-Fluoro-4-hydroxy-1,4-diazoniabicyclo[2.2.2]octane bis(tetrafluoroborate) has been used for the monofluorination of ketones,¹³¹ as has a mixture of KI-KIO₃-H₂SO₄.¹³² Active compounds, such as β -keto esters and β -diketones, have been fluorinated with an *N*-fluoro-*N*-alkylsulfonamide¹³³ (this can result in enantioselective fluorination, if an optically active *N*-fluorosulfonamide is used¹³⁴), with F₂/N₂-HCOOH,¹³⁵ with NF₃O/Bu₄NOH,¹³⁶ and with acetyl hypofluorite.¹³⁷ The last reagent also fluorinates simple ketones in the form of their lithium enolates.¹³⁸

For unsymmetrical ketones, the preferred position of halogenation is usually the more substituted: a CH group, then a CH₂ group, and then CH₃;¹³⁹ however, mixtures are frequent. With aldehydes the aldehydic hydrogen is sometimes replaced (see 14-4). It is also possible to prepare di- and polyhalides. When basic catalysts are used, one a position of a ketone is completely halogenated before the other is

¹³⁹For chlorination this is reversed if the solvent is methanol: Gallucci, R.R.; Going, R. *J. Org. Chem.* **1981**, *46*, 2532.

attacked, and the reaction cannot be stopped until all the hydrogens of the first carbon have been replaced (see below). If one of the groups is methyl, the haloform reaction (**12-44**) takes place. With acid catalysts, it is easy to stop the reaction after only one halogen has entered, although a second halogen can be introduced by the use of excess reagent. In chlorination the second halogen generally appears on the same side as the first,¹⁴⁰ while in bromination the α,α' -dibromo product is found.¹⁴¹ Actually, with both halogens it is the α,α' -dihalo ketone that is formed first, but in the case of bromination this compound isomerizes under the reaction conditions to the α,α' isomer.¹⁴⁰ α,α' -Dichloro ketones are formed by reaction of a methyl ketone with an excess of CuCl_2 and LiCl in DMF ¹⁴² or with HCl and H_2O_2 in methanol.¹⁴³ Aryl methyl ketones can be dibrominated ($\text{ArCOCH}_3 \rightarrow \text{ArCOCHBr}_2$) in high yields with benzyltrimethylammonium tribromide.¹⁴⁴ Active methylene compounds are chlorinated with NCS and $\text{Mg}(\text{ClO}_4)_2$.¹⁴⁵ Similar chlorination in the presence of a chiral copper catalyst led to α -chlorination with modest enantioselectivity.¹⁴⁶

It is not the aldehyde or ketone itself that is halogenated, but the corresponding enol or enolate ion. The purpose of the catalyst is to provide a small amount of enol or enolate. The reaction is often done without addition of acid or base, but traces of acid or base are always present, and these are enough to catalyze formation of the enol or enolate. With acid catalysis the mechanism is

¹⁴⁶Marigo, M.; Kumaragurubaran, N.; Jørgensen, K.A. *Chem. Eur. J.* **2004**, 10, 2133.

The first step, as we have already seen (12-3), actually consists of two steps. The second step is very similar to the first step in electrophilic addition to double bonds (p. 999). There is a great deal of evidence for this mechanism: (1) the rate is first order in substrate; (2) bromine does not appear in the rate expression at all,¹⁴⁷ a fact consistent with a rate-determining first step;¹⁴⁸ (3) the reaction rate is the same for bromination, chlorination, and iodination under the same conditions;¹⁴⁹ (4) the reaction shows an isotope effect; and (5) the rate of the step 2–step 3 sequence has been independently measured (by starting with the enol) and found to be very fast.¹⁵⁰

With basic catalysts the mechanism may be the same as that given above (since bases also catalyze formation of the enol), or the reaction may go directly through the enolate ion without formation of the enol:

It is difficult to distinguish the two possibilities. It was mentioned above that in the base-catalyzed reaction, if the substrate has two or three halogens on the same side of the C=O group, it is not possible to stop the reaction after just one halogen atom has entered. The reason is that the electron-withdrawing field effect of the first halogen increases the acidity of the remaining hydrogens, that is, a CHX group is more acidic than a CH₂ group, so that initially formed halo ketone is converted to enolate ion (and hence halogenated) more rapidly than the original substrate. Other halogenating agents can be used in this reaction. Reaction of a lithium enolate anion with tosyl chloride gave the corresponding α -chloro ketone.¹⁵¹ When an aldehyde was treated with a catalytic amount of 2,5-lutidine to generate the enolate anion, reaction with 35% HCl in dichloromethane gave the α,α -dichloroaldehyde.¹⁵²

¹⁴⁷When the halogenating species is at low concentration or has a low reactivity, it can appear in the rate expression. The reaction becomes first order in the halogenating species. See, for example, Tapuhi, E.; Jencks, W.P. *J. Am. Chem. Soc.* **1982**, *104*, 5758. For a case in which the reaction is first order in bromine, even at relatively high Br₂ concentration, see Pinkus, A.G.; Gopalan, R. *J. Am. Chem. Soc.* **1984**, *106*, 2630. For a study of the kinetics of iodination, see Pinkus, A.G.; Gopalan, R. *Tetrahedron* **1986**, *42*, 3411.

¹⁴⁸Under some conditions it is possible for step 2 to be rate-determining: Deno, N.C.; Fishbein, R. *J. Am. Chem. Soc.* **1973**, *95*, 7445.

Regioselectivity in the halogenation of unsymmetrical ketones can be attained by treatment of the appropriate enol borinate of the ketone with *N*-bromo- or *N*-chlorosuccinimide.¹⁵³ The desired halo

ketone is formed in high yield. Another method for achieving the same result involves bromination of the appropriate lithium enolate at a low temperature¹⁵⁴ (see p. 630 for the regioselective formation of enolate ions). In a similar process, α -halo aldehydes have been prepared in good yield by treatment of silyl enol ethers $\text{R}_2\text{C}=\text{CHOSiMe}_3$ with Br_2 or Cl_2 ,¹⁵⁵ with sulfonyl chloride SO_2Cl_2 ,¹⁵⁶ or with I_2 and silver acetate.¹⁵⁷ Other chlorinating agents can be used with a variety of silyl enol ethers to generate α -chloroketones with good enantioselectivity, including ZrCl_4 in conjunction with an α,α -dichloromalonate ester.¹⁵⁸ Silyl enol ethers can also be fluorinated, with XeF_2 ¹⁵⁹ or with 5% F_2 in N_2 at -78°C in CCl_3 .¹⁶⁰ Enol acetates have been regioselectively iodinated with I_2 and either thallium(I) acetate¹⁶¹ or copper(II) acetate.¹⁶²

α,β -Unsaturated ketones can be converted to α -halo- α,β -unsaturated ketones by treatment with phenylselenium bromide or chloride,¹⁶³ and to α -halo- β,γ -unsaturated ketones by two-phase treatment with HOCl .¹⁶⁴ Conjugated ketones were converted to the α -bromo conjugated ketone (a vinyl bromide) using the Dess–Martin periodinane (see p. 1723) and tetraethylammonium bromide.¹⁶⁵

12-5 Halogenation of Carboxylic Acids and Acyl Halides

Halogenation or Halo-de-hydrogenation

Using a phosphorus halide as catalyst, the α hydrogens of carboxylic acids can be replaced by bromine or chlorine.¹⁶⁶ The reaction, known as the *Hell-Volhard-Zelinskii reaction*, is not applicable to iodine or fluorine. When there are two α hydrogens, one or both may be replaced, although it is often hard to stop with just one. The reaction actually takes place on the acyl halide formed from the carboxylic acid and the catalyst. The acids alone are inactive, except for those with relatively high enol content, such as malonic acid. Less than one full mole of catalyst (per mole of substrate) is required, because of the exchange reaction between carboxylic acids and acyl halides (see 16-79). Each molecule of acid is α halogenated while it is in the acyl halide stage. The halogen from the catalyst does not enter the α position. For example, the use of Cl_2 and PBr_3 results in α chlorination, not bromination. As expected from the foregoing, acyl halides undergo a halogenation without a catalyst. An enantioselective α -halogenation was reported yielding via an alkaloid catalyzed reaction of acyl halides with perhaloquinone-derived reagents to give to chiral α -haloesters.¹⁶⁷ So do anhydrides and many compounds that enolize easily (e.g., malonic ester and aliphatic nitro compounds). The mechanism is usually regarded as proceeding through the enol as in 12-4.¹⁶⁸ If chlorosulfuric acid ClSO_2OH is used as a catalyst, carboxylic acids can be α -iodinated,¹⁶⁹ as well as chlorinated or brominated.¹⁷⁰ *N*-Bromosuccinimide in a mixture of sulfuric acid–trifluoroacetic acid can mono-brominate simple carboxylic acids.¹⁷¹

A number of other methods exist for the α halogenation of carboxylic acids or their derivatives.¹⁷² Under electrolytic conditions with NaCl , malonates are converted to 2-chloro malonates.¹⁷³ Acyl halides can be α brominated or chlorinated by use of *N*-bromo- or *N*-chlorosuccinimide and HBr or HCl .¹⁷⁴ The latter is an ionic, not a free-radical halogenation (see 14-3). Direct iodination of carboxylic acids has been achieved with I_2 - Cu(II) acetate in HOAc .¹⁷⁵ Acyl chlorides can

12-6 Halogenation of Sulfoxides and Sulfones

Halogenation or Halo-de-hydrogenation

Sulfoxides can be chlorinated in the α position¹⁸⁰ by treatment with Cl_2 ¹⁸¹ or *N*-chlorosuccinimide,¹⁸² in the presence of pyridine. These methods involve basic conditions. The reaction can also be accomplished in the absence of base with SO_2Cl_2 in CH_2Cl_2 ,¹⁸³ or with TsNCl_2 .¹⁸⁴ The bromination of sulfoxides with bromine¹⁸⁵ and with NBS-bromine¹⁸⁶ have also been reported. Sulfones have been chlorinated by treatment of their conjugate bases $\text{RSO}_2\text{C}^\ominus\text{HR}'$ with various reagents, among them SO_2Cl_2 , CCl_4 ,¹⁸⁷ *N*-chlorosuccinimide,¹⁸⁸ and hexachloroethane.¹⁸⁹ The α fluorination of sulfoxides has been accomplished in a two-step procedure. Treatment with diethylaminosulfur trifluoride Et_2NSF_3 (DAST) produces an

α -fluoro thioether, usually in high yield. Oxidation of this compound with *m*-chloroperoxybenzoic acid gives the sulfoxide.¹⁹⁰

C. Nitrogen Electrophiles

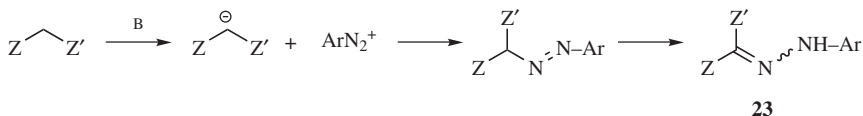

12-7 Aliphatic Diazonium Coupling

Arylhydrazone-de-dihydro-bisubstitution

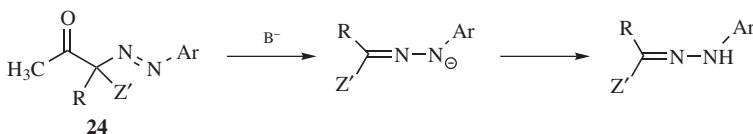

If a C–H bond is acidic enough, it couples with diazonium salts in the presence of a base, most often aqueous sodium acetate.¹⁹¹ The reaction is commonly carried out on compounds of the form Z–CH₂–Z', where Z and Z' are as defined on p. 1358, for example, β -keto esters, β -keto amides, malonic ester.

The mechanism is probably of the simple S_E1 type:

Aliphatic azo compounds in which the carbon containing the azo group is attached to a hydrogen are unstable and tautomerize to the isomeric hydrazones (**23**), which are therefore the products of the reaction.

When the reaction is carried out on a compound of the form Z–CHR–Z', so that the azo compound does not have a hydrogen that can undergo tautomerism, if at least one Z is acyl or carboxyl, this group usually cleaves:

so the product in this case is also the hydrazone, and not the azo compound. In fact, compounds of the type **24** are seldom isolable from the reaction, although this has been accomplished.¹⁹² The cleavage step shown is an example of **12-43** and, when a carboxyl group cleaves, of **12-40**. The overall process in this case is called the *Japp-Klingemann reaction*¹⁹³ and involves conversion of a ketone (**25**) or a

carboxylic acid (**26**)

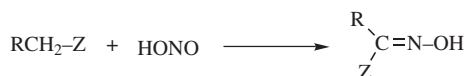

to a hydrazone (**27**). When an acyl and a carboxyl group are both present, the leaving group order has been reported to be $\text{MeCO} > \text{COOH} > \text{PhCO}$.¹⁹⁴ When there is no acyl or carboxyl group present, the aliphatic azo compound is stable.

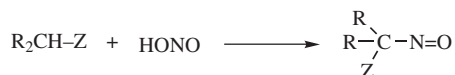

OS III, 660; IV, 633.

12-8 Nitrosation at a Carbon Bearing an Active Hydrogen

Hydroxyimino-de-dihydro-bisubstitution

Nitrosation or Nitroso-de-hydrogenation

Carbons adjacent to a Z group (as defined on p. 622) can be nitrosated with nitrous acid or alkyl nitrites.¹⁹⁵ The initial product is the C-nitroso compound, but these are stable only when there is no hydrogen that can undergo tautomerism. When there is, the product is the more stable oxime. The situation is analogous to that with azo compounds and hydrazones (**12-7**). The mechanism is similar to that in **12-7**:¹⁹⁶ $\text{R-H} \rightarrow \text{R}^- + {}^+\text{N}=\text{O} \rightarrow \text{R-N}=\text{O}$. The attacking species is either NO^+ or a carrier of it. When the substrate is a simple ketone, the mechanism goes through the enol (as in halogenation **12-4**):

Evidence is that the reaction, in the presence of X^- (Br^- , Cl^- , or SCN^-), was first order in ketone and in H^+ , but zero order in HNO_2 and X^- .¹⁹⁷ Furthermore, the rate of the nitrosation was about the same as that for enolization of the same ketones. The species NOX is formed by $\text{HONO} + \text{X}^- + \text{H}^+ \rightarrow \text{HOX} + \text{H}_2\text{O}$. In

the cases of $F_3CCOCH_2COCF_3$ and malononitrile the nitrosation went entirely through the enolate ion rather than the enol.¹⁹⁸

As in the Japp–Klingemann reaction, when Z is an acyl or carboxyl group (in the case of R_2CH-Z), it can be cleaved. Since oximes and nitroso compounds can be reduced to primary amines, this reaction often provides a route to amino acids. As in the case of **12-4**, the silyl enol ether of a ketone can be used instead of the ketone itself.¹⁹⁹ Good yields of α -oximinoketones (**28**) can be obtained by treating ketones with *tert*-butyl thionitrate.²⁰⁰

Imines can be prepared in a similar manner by treatment of an active hydrogen compound with a nitroso compound:

Alkanes can be nitrosated photochemically, by treatment with NOCl and UV light.²⁰¹ For nitration at an activated carbon, see **12-9**. Trialkyltin enol ethers ($C=C-O-SnR_3$) react with PhNO to give α -(*N*-hydroxylamino)ketones.²⁰²

²⁰²Momiyama, N.; Yamamoto, H. *Org. Lett.* **2002**, 4, 3579.

Nitration of alkanes²⁰³ can be carried out in the gas phase at $\sim 400^\circ\text{C}$ or in the liquid phase. The reaction is not practical for the production of pure products for any alkane except methane. For other alkanes, not only does the reaction produce mixtures of the mono-, di-, and polynitrated alkanes at every combination of positions, but extensive chain cleavage occurs.²⁰⁴ A free-radical mechanism is involved.²⁰⁵

Activated positions (e.g., $\text{ZCH}_2\text{Z}'$ compounds) can be nitrated by fuming nitric acid in acetic acid, by acetyl nitrate and an acid catalyst,²⁰⁶ or by alkyl nitrates under alkaline conditions.²⁰⁷ In the latter case, it is the carbanionic form of the substrate that is actually nitrated. What is isolated under these alkaline conditions is the conjugate base of the nitro compound. Yields are not high. Of course, the mechanism in this case is not of the free-radical type, but is electrophilic substitution with respect to the carbon (similar to the mechanisms of **12-7** and **12-8**). Positions activated by only one electron-withdrawing group, for example, a positions of simple ketones, nitriles, sulfones, or *N,N*-dialkyl amides, can be nitrated with alkyl nitrates if a very strong base, for example, *t*-BuOK or NaNH_2 , is present to convert the substrate to the carbanionic form.²⁰⁸

Electrophilic nitration of alkanes has been performed with nitronium salts, for example, $\text{NO}_2^+ \text{PF}_6^-$ and with $\text{HNO}_3\text{--H}_2\text{SO}_4$ mixtures, but mixtures of nitration and cleavage products are obtained and yields are generally low.²⁰⁹ The reaction of alkanes with nitric acid and *N*-hydroxysuccinimide (NHS), however, gave moderate-to-good yields of the corresponding nitroalkane.²¹⁰ Similar nitration was accomplished with NO_2 , NHS and air.²¹¹

Aliphatic nitro compounds can be a nitrated [$\text{R}_2\text{C}^\ominus\text{NO}_2 \rightarrow \text{R}_2\text{C}(\text{NO}_2)_2$] by treatment of their conjugate bases RCNO_2 with NO_2^- and $\text{K}_3\text{Fe}(\text{CN})_6$.²¹²

A novel reaction converted a vinyl methyl moiety to a vinyl nitro. The reaction of $\text{MeCH}=\text{C}(\text{Ph})\text{CN}$ with NO_x and iodine gave $\text{O}_2\text{NCH}=\text{C}(\text{Ph})\text{CN}$.²¹³

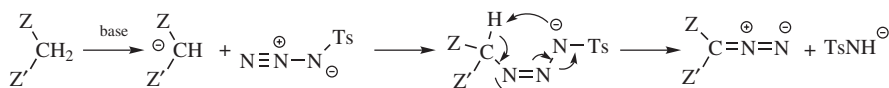

OS I, 390; II, 440, 512.

12-10 Direct Formation of Diazo Compounds

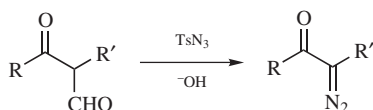

Diazo-de-dihydro-bisubstitution

Compounds containing a CH_2 bonded to two Z groups (active methylene compounds, with Z as defined on p. 622) can be converted to diazo compounds on treatment with tosyl azide in the presence of a base.²¹⁴ The use of phase-transfer catalysis increases the convenience of the method.²¹⁵ *p*-Dodecylbenzenesulfonyl azide,²¹⁶ methanesulfonyl azide,²¹⁷ and *p*-acetamidobenzenesulfonyl azide²¹⁸ also give the reaction. The reaction, which is called the *diazo-transfer reaction*, can also be applied to other reactive positions (e.g., the 5 position of cyclopentadiene).²¹⁹ The mechanism is probably as follows:

A diazo group can be introduced adjacent to a single carbonyl group indirectly by first converting the ketone to an α -formyl ketone (**16-85**) and then treating it with tosyl azide. As in the similar cases of

12-7 and **12-8**, the formyl group is cleaved during the reaction.²²⁰

12-11 Conversion of Amides to α -Azido Amides

Azidation or Azido-de-hydrogenation

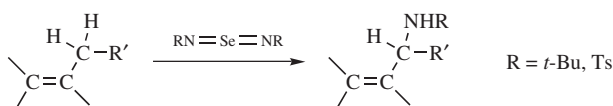

In reaction **12-10**, treatment of $Z\text{-CH}_2\text{-Z}'$ with tosyl azide gave the α -diazo compound via diazo transfer. When this reaction is performed on a compound with a single Z group such as an amide, formation of the azide becomes a competing process via the enolate anion.²²¹ Factors favoring azide formation rather than diazo transfer include K^+ as the enolate counterion rather than Na^+ or Li^+ and the use of 2,4,6-triisopropylbenzenesulfonyl azide rather than TsN_3 . When the reaction was applied to amides with a chiral R' , such as the oxazolidinone derivative **29**, it was highly stereoselective, and the product could be converted to an optically active amino acid.²²¹

12-12 Direct Amination at an Activated Position

Alkyamino-de-hydrogenation, and so on

Alkenes can be aminated²²² in the allylic position by treatment with solutions of imido selenium compounds $R\text{-N=Se=N-R}$.²²³ The reaction, which is similar to the allylic oxidation of alkenes with SeO_2 (see **19-14**), has been performed with $R = t\text{-Bu}$ and $R = Ts$. The imido sulfur compound $TsN=S=NTs$ has also been used,²²⁴ as well

For a review, see Cheikh, R.B.; Chaabouni, R.; Laurent, A.; Mison, P.; Nafti, A. *Synthesis* **1983**, 685, pp. 691–696.

²²⁴Sharpless, K.B.; Hori, T. *J. Org. Chem.* **1979**, *41*, 176; Singer, S.P.; Sharpless, K.B. *J. Org. Chem.* **1978**, *43*, 1448. For other reagents, see Mahy, J.P.; Bedi, G.; Battioni, P.; Mansuy, D. *Tetrahedron Lett.* **1988**, *29*, 1927; Tsushima, S.; Yamada, Y.; Onami, T.; Oshima, K.; Chaney, M.O.; Jones, N.D.; Swartzendruber, J.K. *Bull. Chem. Soc. Jpn.* **1989**, *62*, 1167.

as $\text{PhNHOH-FeCl}_2/\text{FeCl}_3$.²²⁵ Benzylic positions can be aminated with *t*-BuOOCONHTs in the presence of a catalytic amount of $\text{Cu}(\text{OTf})_2$.²²⁶ In another reaction, compounds containing an active hydrogen can be converted to primary amines (**30**) in moderate yields by treatment with *O*-(2,4-dinitrophenyl)hydroxylamine.²²⁷

Tertiary alkyl hydrogen can be replaced in some cases via C–H nitrogen insertion. The reaction of sulfamate ester **31** with $\text{PhI}(\text{OAc})_2$, MgO and a dinuclear Rh carboxylate catalyst, for example, generated oxathiazinane **32**.²²⁸ This transformation is a formal oxidation, and primary carbamates have been similarly converted to oxazolidin-2-ones.²²⁹

In an indirect amination process, acyl halides are converted to amino acids.²³⁰ Reaction of the acyl halide with a chiral oxazolidinone leads to a chiral amide, which reacts with the $\text{N}=\text{N}$ unit of a dialkyl azodicarboxylate [$\text{R}^2\text{O}_2\text{C}-\text{N}=\text{N}-\text{CO}_2\text{R}'$]. Hydrolysis and catalytic hydrogenation leads to an amino acid with good enantioselectivity.²²⁶

Carbonylnitrenes: NCOW ($W = R', Ar, \text{ or } OR'$) are very reactive species (p. 293) and insert into the C–H bonds of alkanes to give amides ($W = R' \text{ or } Ar$) or carbamates ($W = OR'$).²³¹ The nitrenes are generated as discussed on p. 293. The order of reactivity among alkane C–H bonds is tertiary > secondary > primary.²³² Indications are that in general it is only singlet and not triplet nitrenes that insert.²³³ Retention of configuration is found at a chiral carbon.²³⁴ The mechanism is presumably similar to the simple one-step mechanism for insertion of carbenes (**12-21**). Other nitrenes [e.g., cyanonitrene (NCN)²³⁵ and aryl nitrenes (NAr)²³⁶] can also insert into C–H bonds, but alkylnitrenes usually undergo rearrangement before they can react with the alkane. *N*-Carbamoyl nitrenes undergo insertion reactions that often lead to mixtures of products, but exceptions are known,²³⁷ chiefly in cyclizations.²³⁸ For example, heating of 2-(2-methylbutyl)phenyl azide gave ~60% 2-ethyl-2-methylindoline.²³⁴ Enantioselective nitrene insertion reactions are known.²³⁹

Sulfonation or Sulfo-de-hydrogenation

Ketones, carboxylic esters (including lactones),²⁴⁰ and amides (including lactams)²⁴¹ can be sulfenylated²⁴² in the α position by conversion to the enolate ion with a base, such as lithium *N*-isopropylcyclohexylamide and subsequent treatment with a disulfide.²⁴³ The reaction, shown above for ketones, involves nucleophilic substitution at sulfur. Analogously, α -phenylseleno ketones $\text{RCH}(\text{SePh})\text{COR}'$ and α -phenylseleno esters $\text{RCH}(\text{SePh})\text{COOR}'$ can be prepared²⁴⁴ by treatment of the corresponding enolate anions with PhSeBr ,²⁴⁵ PhSeSePh ,²⁴⁶ or benzeneseleninic anhydride $\text{PhSe}(\text{O})\text{OSe}(\text{O})\text{Ph}$.²⁴⁷ Another method for the introduction of a phenylseleno group into the α position of a ketone involves simple treatment of an ethyl acetate solution of the ketone with PhSeCl (but not PhSeBr) at room temperature.²⁴⁸ This procedure is also successful for aldehydes, but not for carboxylic esters. *N*-Phenylselenophthalimide has been used to convert ketones²⁴⁹ and aldehydes²⁵⁰ to the α -PhSe derivative. In another method that avoids the use of PhSeX reagents, a ketone enolate is treated with selenium to give an $\text{R}'\text{COCHRSe}^-$ ion, which is treated with MeI , producing the α -methylseleno ketone $\text{R}'\text{COCHRSeMe}$.²⁵¹ This method has also been applied to carboxylic esters.

Silyl enol ethers are converted to α -thioalkyl and α -thioaryl ketones via a sulfenylation method, driven by aromatization of an added quinone mono-*O,S*-acetal in the presence of Me_3SiOTf .²⁵²

The α -seleno and α -sulfenyl carbonyl compounds prepared by this reaction can be converted to α,β -unsaturated carbonyl compounds (**17-12**). The sulfenylation reaction has also been used²⁵³ as a key step in a sequence for moving the position of a carbonyl group to an adjacent carbon.²⁵⁴

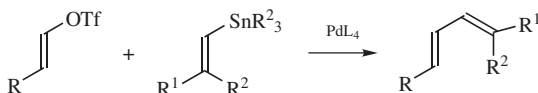

Aldehydes, ketones, and carboxylic acids containing α hydrogens can be sulfonated with sulfur trioxide.²⁵⁵ The mechanism is presumably similar to that of **12-4**. Sulfonation has also been accomplished at vinylic hydrogen.

E. Carbon Reagents

12-15 Arylation and Alkylation of Alkenes

Alkylation or Alkyl-de-oxysulfonation (de-halogenation), Arylation or Aryl-de-oxysulfonation (de-halogenation), and so on

Vinyl triflates ($\text{C}=\text{C}-\text{OSO}_2\text{CF}_3$) react with vinyl tin derivatives in the presence of palladium catalysts to form dienes, in what is known as the *Stille coupling*.²⁵⁶ Vinyl triflates can be prepared from the enolate by reaction with *N*-phenyl triflimide.²⁵⁷ Vinyltin compounds are generally prepared by the reaction of an alkyne with an trialkyltin halide (see **15-17** and **15-21**).²⁵⁸ Still cross-coupling reactions are quite important.²⁵⁹ Stille reactions are compatible with many functional groups,

proceed with a retention of geometry of the C=C units, and are usually regioselective with respect to the newly formed C–C σ -bond. Vinyl halides can be used,²⁶⁰ and allenic tin compounds have been used.²⁶¹ Intramolecular reactions are possible.²⁶² Stille coupling has been done using microwave irradiation,²⁶³ in fluorosolvents,²⁶⁴ and in supercritical carbon dioxide (see p. 415).²⁶⁵ One-pot hydrostannylation/Stille coupling has been reported using catalytic amounts of tin with alkyne substrates reacting with vinyl halides.²⁶⁶

This reaction is highly stereoselective. Cine substitution is known with this reaction, and its mechanism has been studied.²⁶⁷ Using ArSnCl_3 derivatives, Stille coupling can be done in aq. KOH.²⁶⁸ A related reaction couples reagents with C=C–I⁺Ph reagents, in the presence of a palladium catalyst.²⁶⁹ Aryl halides²⁷⁰ and heteroaryl halides²⁷¹ can be coupled to vinyltin reagents²⁷² using a palladium catalyst. Vinylation of heteroaryl triflates²⁷³ also possible. Vinyl halides can be coupled to alkenes to form dienes.²⁷⁴ The reaction of dihydrofurans with vinyl triflates and a palladium catalyst leads to a nonconjugated diene, **33**.²⁷⁵ This example illustrates that the product is formed by an elimination step, as with the Heck reaction (**13-10**), and double bond migration can occur resulting in allylic rearrangement.

The accepted mechanism for the Stille reaction involves a catalytic cycle²⁷⁶ in which an oxidative addition²⁷⁷ and a reductive elimination step²⁷⁸ are fast, relative to Sn/Pd transmetalation (the rate-determining step).²⁷⁹ It appears that the more coordinatively unsaturated species, probably with a coordinated solvent molecule, is involved in the electrophilic substitution at tin. Another mechanism has been proposed, in which oxidative addition of the vinyl triflate to the ligated palladium gives a *cis*-palladium complex that isomerizes rapidly to *trans*-palladium complex, which then reacts with the organotin compound following a S_E2 (cyclic) mechanism, with release of a ligand.²⁸⁰ This pathway gives a bridged intermediate, and subsequent elimination of XSnBu₃ yields a three-coordinate species *cis*-palladium complex, which readily gives the coupling product.²⁸⁰

Cyclopropylboronic acids (**12-28**) couple with vinylic halides²⁸¹ or vinyl triflates²⁸² to give vinylcyclopropanes, using a palladium catalyst. Vinyl borates (**12-28**) were coupled to vinyl triflates using a palladium catalyst.²⁸³ In a variation, phenylboronic acid reacted with a symmetrical internal alkyne and a nickel catalyst to give a conjugated diene bearing a phenyl group.²⁸⁴ Stille coupling to enols has been reported.²⁸⁵ A variation of this latter reaction coupled vinyl triflates to vinyl ethers, without a palladium catalyst, but using microwave irradiation.²⁸⁶ The

coupling of vinyl silanes to give the symmetrically conjugated diene using CuCl and air was reported.²⁸⁷ Vinyl zinc halides were coupled to 1-halo enol ether to give a conjugated diene bearing a vinyl ether unit, using a palladium catalyst.²⁸⁸ Tertiary propargyl alcohols ($R-C=C-CMe_2OH$) are coupled to conjugated alkenes in a Heck-like process using a palladium catalyst and oxygen to give the conjugated ene-yne.²⁸⁹

Coupling is not restricted to two vinyl units or an aryl with a vinyl. 1-Lithioalkynes were coupled to vinyl tellurium compounds ($C=C-TeBu$) using a nickel catalyst²⁹⁰ or a palladium catalyst²⁹¹ to give a conjugated en-yne. 2-Alkynes ($R-C=C-Me$) react with $HgCl_2$, *n*-butyllithium, and $ZnBr_2$, sequentially, and then with vinyl iodides and a palladium catalyst to give the nonconjugated en-yne.²⁹² Alkynyl groups can be coupled to vinyl groups to give ene-ynes, via reaction of silver alkynes ($Ag-C=C-R$) with vinyl triflates and a palladium catalyst.²⁹³ In the presence of CuI and a palladium catalyst, vinyl triflates²⁹⁴ or vinyl halides²⁹⁵ couple to terminal alkynes. Alkynyl zinc reagents ($R-C=C-ZnBr$) can be coupled to vinyl halides with a palladium catalyst to give the conjugate ene-yne.²⁹⁶

Alkyl groups can be coupled to a vinyl unit to give substituted alkenes. The reaction of vinyl iodides and $EtZnBr$, with a palladium catalyst, gave the ethylated alkene ($C=C-Et$).²⁹⁷ A similar coupling reaction was observed with $RZnI$ reagents and vinyl nitro compounds ($C=C-NO_2$), which gave the alkyne ($C=C-R$) with microwave irradiation.²⁹⁸ Aliphatic alkyl bromides reacted with vinyltin compounds to give the alkylated alkene using a palladium catalyst.²⁹⁹ Allylic tosylates were coupled to conjugated alkenes to give a non-conjugated diene using a palladium catalyst.³⁰⁰ An internal coupling reaction was reported in which an alkenyl enamide (**34**) reacted with Ag_3PO_4 and a chiral palladium catalyst to give **35** enantioselectively.³⁰¹

12-16 Acylation at an Aliphatic Carbon

Acylation or Acyl-de-hydrogenation

Alkenes can be acylated with an acyl halide and a Lewis acid catalyst in what is essentially a Friedel–Crafts reaction at an aliphatic carbon.³⁰² The product can arise by two paths. The initial attack is by the π -bond of the alkene unit on the acyl cation (RCO^+ ; or on the acyl halide free or complexed; see **11-17**) to give a carbocation, **36**.

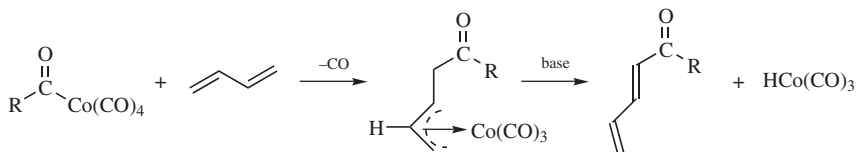

Ion **36** can either lose a proton or combine with chloride ion. If it loses a proton, the product is an unsaturated ketone; the mechanism is similar to the tetrahedral mechanism of Chapter 10, but with the charges reversed. If it combines with chloride, the product is a β -halo ketone, which can be isolated, so that the result is addition to the double bond (see **15-47**). On the other hand, the β -halo ketone may, under the conditions of the reaction, lose HCl to give the unsaturated ketone, this time by an addition–elimination mechanism. In the case of unsymmetrical alkenes, the more stable alkene is formed (the more highly substituted and/or conjugated alkene, following Markovnikov's rule, see p. 1019). Anhydrides and carboxylic acids (the latter with a proton acid such as anhydrous HF , H_2SO_4 , or polyphosphoric acid as a catalyst) are sometimes used instead of acyl halides. With some sub-

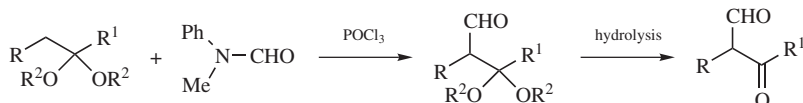

³⁰²For reviews, see Groves, E.E. *Chem. Soc. Rev.* **1972**, *1*, 73; Satchell, D.P.N.; Satchell, R.S., in Patai, S. *The Chemistry of the Carbonyl Group*, Vol. 1, Wiley, NY, **1966**, pp. 259–266, 270–273; Nenitzescu, C.D.; Balaban, A.T., in Olah, G.A. *Friedel–Crafts and Related Reactions*, Vol. 3, Wiley, NY, **1964**, pp. 1033–1152.

strates and catalysts double-bond migrations are occasionally encountered so that, for example, when 1-methylcyclohexene was acylated with acetic anhydride and zinc chloride, the major product was 6-acetyl-1-methylcyclohexene.³⁰³

Conjugated dienes can be acylated by treatment with acyl- or alkylcobalt tetracarbonyls, followed by base-catalyzed cleavage of the resulting π -allyl carbonyl derivatives³⁰⁴ (π -allyl metal complexes were discussed on p. 117. The reaction is very general. With unsymmetrical dienes, the acyl group generally substitutes most readily at a cis double bond, next at a terminal alkenyl group, and least readily at a trans double bond. The most useful bases are strongly basic, hindered amines, such as dicyclohexylethylamine. The use of an alkylcobalt tetracarbonyl $\text{RCo}(\text{CO})_4$ gives the same product as that shown above. Acylation of vinylic ethers has been accomplished with aromatic acyl chlorides, a base, and a palladium catalyst: $\text{ROCH}=\text{CH}_2 \rightarrow \text{ROCH}=\text{CHCOAr}$.³⁰⁵

Formylation of alkenes can be accomplished with *N*-disubstituted formamides and POCl_3 .³⁰⁶ This is an aliphatic Vilsmeier reaction (see **11-18**). Vilsmeier formylation can also be performed on the α position of acetals and ketals, so that hydrolysis of the products gives keto aldehydes or dialdehydes.³⁰⁷ A variation of this reaction heated a 1,1-dibromoalkene with a secondary amine in aq. DMF to give the corresponding amide.³⁰⁸

Acetylation of acetals or ketals can be accomplished with acetic anhydride and BF_3 -etherate.³⁰⁹ The mechanism with acetals or ketals also involves attack at an

12-17 Conversion Of Enolates to Silyl Enol Ethers, Silyl Enol Esters, and Silyl Enol Sulfonate Esters

3/O-Trimethylsilyl-de-hydrogenation

Silyl enol ethers,³¹¹ important reagents with a number of synthetic uses (see, e.g., 10-68, 12-4, 15-24, 15-64, 16-36), can be prepared by base treatment of a ketone (converting it to its enolate anion) followed by addition of a trialkylchlorosilane. Other silylating agents have also been used.³¹² Both strong bases, e.g., lithium diisopropylamide (LDA), and weaker bases (e.g. Et₃N) have been used for this purpose.

In some cases, the base and the silylating agent can be present at the same time.³¹³ Enolates prepared in other ways (e.g., as shown on p. 603) also give the reaction.³¹⁴ The reaction can be applied to aldehydes by the use of the base KH in 1,2-dimethoxyethane.³¹⁵ A particularly mild method for conversion of ketones

or aldehydes to silyl enol ethers uses Me_3SiI and the base hexamethyldisilazane, $(\text{Me}_3\text{Si})_2\text{NH}$.³¹⁶ Cyclic ketones can be converted to silyl enol ethers in the presence of acyclic ketones, by treatment with Me_3SiBr , tetraphenylstibonium bromide, Ph_4SbBr , and an aziridine.³¹⁷ bis(trimethylsilyl)acetamide is an effective reagent for the conversion of ketones to the silyl enol ether, typically giving the thermodynamic product (see below).³¹⁸ Silyl enol ethers have also been prepared by the direct reaction of a ketone and a silane (R_3SiH) with a platinum complex catalyst.³¹⁹

Unsymmetrical ketones can give the more substituted (thermodynamic) silyl enol ether or the less substituted (kinetic) product, depending on the use of thermodynamic conditions (protic solvents, e.g., ethanol, water, or ammonia; a base generating a conjugate acid stronger than the starting ketone; more ionic counterions, e.g., K or Na; higher temperatures and longer reaction times) or kinetic conditions (aprotic solvents, such as ether or THF; a base generating a conjugate acid weaker than the starting ketone; more covalent counterions, e.g., Li; lower temperatures and relatively short reaction times). Other reaction conditions have been developed to control or influence the relative amounts of kinetic or thermodynamic silyl enol ether. Magnesium diisopropyl amide has been used to prepare kinetic silyl enol ethers in virtual quantitative yield.³²⁰ Reaction with $\text{Me}_3\text{SiCl/KI}$ in DMF gives primarily the thermodynamic silyl enol ether.³²¹ The reaction of an unsymmetrical ketone with Mg and TMSCl in DMF gives a roughly 2:1 mixture of thermodynamic: kinetic silyl enol ether.³²²

An interesting synthesis of silyl enol ethers involves chain extension of an aldehyde. Aldehydes are converted to the silyl enol ether of a ketone upon reaction with lithium (trimethylsilyl)diazomethane and then a dirhodium catalyst.³²³ Initial reaction of lithium(trimethylsilyl)diazomethane [LTMSD, prepared *in situ* by reaction of butyllithium with (trimethylsilyl)diazomethane] to the aldehyde (e.g., **37**) gave the alkoxide addition product. Protonation, and then capture by a transition-metal catalyst, and a 1,2-hydride migration gave the silyl enol ether, **38**.

Enol acetates are generally prepared by the reaction of an enolate anion with a suitable acylating reagent.³²⁴ Enolate anions react with acyl halides and with anhydrides to give the acylated product. Both *C*-acylation and *O*-acylation are possible, but in general *O*-acylation predominates.³²⁵ Note that the extent of *O*- versus *C*-acylation is very dependent on the local environment and electronic effects within the enolate anion.³²⁶ Silyl sulfonate esters can be prepared by similar methods, using sulfonic acid anhydrides rather than carboxylic anhydrides. A polymer-supported triflating agent was used to prepare silyl enol triflate from ketones, in the presence of diisopropylethylamine.³²⁷

When a silyl enol ether is the trimethylsilyl derivative ($\text{Me}_3\text{Si-O-C}=\text{C}$), treatment with methylolithium will regenerate the lithium enolate anion and the volatile trimethylsilane (Me_3SiH).³²⁸ The enolate anion can be used in the usual reactions. In a similar reaction, a trimethylsilyl enol ether was treated with Cp_2Zr (from $\text{Cp}_2\text{ZrCl}_2/2 \text{ BuLi/THF}/-78^\circ\text{C}$), and subsequent quenching with D_2O led to incorporation of deuterium at the vinyl carbon ($\text{C}=\text{C}-\text{D}$).³²⁹

12-18 Conversion of Aldehydes to β -Keto Esters or Ketones

Alkoxy-carbonylalkylation or Alkoxy-carbonylalkyl-de-hydrogenation

β -Keto esters have been prepared in moderate to high yields by treatment of aldehydes with diethyl diazoacetate in the presence of a catalytic amount of a Lewis acid, such as SnCl_2 , BF_3 , or GeCl_2 .³³¹ The reaction was successful for both aliphatic and aromatic aldehydes, but the former react more rapidly than the latter, and the

difference is great enough to allow selective reactivity. In a similar process, aldehydes react with certain carbanions stabilized by boron, in the presence of $(F_3CCO)_2O$ or NCS, to give ketones.³³²

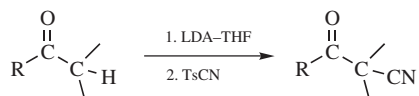

Ketones can be prepared from aryl aldehydes (ArCHO) by treatment with a rhodium complex $(\text{Ph}_3\text{P})_2\text{Rh}(\text{CO})\text{Ar}'$, whereby the Ar group is transferred to the aldehyde, producing the ketone, $\text{Ar}-\text{CO}-\text{Ar}'$.³³³ In a rhodium catalyzed reaction, aryl aldehydes (ArCHO) react with $\text{Me}_3\text{SnAr}'$ to give the diaryl ketone $\text{Ar}-\text{CO}-\text{Ar}'$.³³⁴

12-19 Cyanation or Cyano-de-hydrogenation

There are several reactions in which a C–H unit is replaced by C–CN. In virtually all cases, the hydrogen being replaced is on a carbon α to a heteroatom or functional group. There are several examples.

Introduction of a cyano group α to the carbonyl group of a ketone can be accomplished by prior formation of the enolate anion with LDA in THF and addition of this solution to *p*-TsCN at -78°C .³³⁵ The products are formed in moderate to high yields but the reaction is not applicable to methyl ketones. Treatment of $\text{TMSCH}_2\text{N}(\text{Me})\text{C}=\text{N}t\text{-Bu}$ with *sec*-butyllithium and $\text{R}_2\text{C}=\text{O}$, followed by iodomethane and NaOMe leads to the nitrile, $\text{R}_2\text{CH}-\text{CN}$.³³⁶

Cyanation has been shown to occur α to a nitrogen, specifically in *N,N*-dimethylaniline derivatives. Treatment with a catalytic amount of RuCl_3 in the presence of oxygen and NaCN leads to the corresponding cyanomethylamine.³³⁷

In a different kind of reaction, nitro compounds are α -cyanated by treatment with ^-CN and $K_3Fe(CN)_6$.³³⁸ The mechanism probably involves ion radicals. In still another reaction, secondary amines are converted to α -cyanoamines by treatment with phenylseleninic anhydride and NaCN or Me_3SiCN .³³⁹ The compound Me_3SiCN has also been used in a reaction that cyanates benzylic positions.³⁴⁰

12-20 Alkylation of Alkanes

Alkylation or Alkyl-de-hydrogenation

Alkanes can be alkylated by treatment with solutions of stable carbocations³⁴¹ (p. 235), but the availability of such carbocations is limited and mixtures are usually obtained. In a typical experiment, the treatment of propane with isopropyl fluoroantimonate ($Me_2C^+ SbF_6^-$) gave 26% 2,3-dimethylbutane, 28% 2-methylpentane, 14% 3-methylpentane, and 32% *n*-hexane, as well as some butanes, pentanes (formed by **12-47**), and higher alkanes. Mixtures arise in part because intermolecular hydrogen exchange ($RH + R'^+ \rightleftharpoons R^+ + R'H$) is much faster than alkylation, so that alkylation products are also derived from the new alkanes and carbocations formed in the exchange reaction. Furthermore, the carbocations present are subject to rearrangement (Chapter 18), giving rise to new carbocations. Products result from all the hydrocarbons and carbocations present in the system. As expected from their relative stabilities, secondary alkyl cations alkylate alkanes more readily than tertiary alkyl cations (the *tert*-butyl cation does not alkylate methane or ethane). Stable primary alkyl cations are not available, but alkylation has been achieved with complexes formed between CH_3F or C_2H_5F and SbF_5 .³⁴² The mechanism of alkylation can be formulated (similar to that shown in hydrogen exchange with superacids, **12-1**) as

It is by means of successive reactions of this sort that simple alkanes like methane and ethane give *tert*-butyl cations in superacid solutions (p. 236).³⁴³

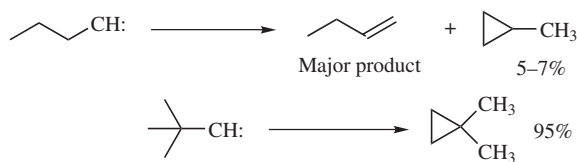

Intramolecular insertion has been reported. The positively charged carbon of the carbocation **40**, generated from the diazonium salt of the triptycene compound **39**, reacted with the CH₃ group in close proximity with it.³⁴⁴

12-21 Insertion by Carbenes

CH-Methylene-insertion

The highly reactive species methylene (:CH₂) inserts into C–H bonds,³⁴⁵ both aliphatic and aromatic,³⁴⁶ although with aromatic compounds subsequent ring expansion is also possible (see **15-64**). This is effectively a homologation reaction.³⁴⁷ The methylene insertion reaction has limited utility because of its non-selectivity (see p. 284). The insertion reaction of carbenes has been used for synthetic purposes.³⁴⁸ The carbenes can be generated in any of the ways mentioned in Chapter 5 (p. 287). Alkylcarbenes usually rearrange rather than give

insertion (p. 291), but, when this is impossible, *intramolecular* insertion³⁴⁹ is found rather than intermolecular.³⁵⁰ Methylene (:CH₂) generated by photolysis of diazomethane (CH₂N₂) in the liquid phase is indiscriminate (totally nonselective) in its reactivity (p. 288). Methylene (:CH₂) generated in other ways and monoalkyl and dialkyl carbenes are less reactive and insert in the order tertiary > secondary > primary.³⁵¹ Carbene insertion with certain allylic systems can proceed with rearrangement of the double bond.³⁵² Carbenes have been generated in the presence of ultrasound.³⁵³ Halocarbenes (:CCl₂, :CBr₂, etc.) insert much less readily, although a number of instances have been reported.³⁵⁴ Insertion into the O–H bond of alcohols, to produce ethers, has been reported using a diazocarbonyl compound and an In(OTf)₃ catalyst.³⁵⁵

For the similar insertion reaction of nitrenes, see 12-13.

The metal carbene insertion reaction, in contrast to the methylene insertion reaction, can be highly selective,³⁵⁶ is very useful in synthesis,³⁵⁷ and there are numerous examples, usually requiring a catalyst.³⁵⁸ The catalyst typically convert a diazoalkane or diazocarbonyl compound to the metal carbene *in situ*, allowing the subsequent insertion reaction. Intermolecular reactions are known, including diazoalkane insertion reaction with a dirhodium catalyst.³⁵⁹ When chiral ligands are present good enantioselectivity is observed in the insertion product.³⁶⁰ Insertion at an allylic carbon of alkenes has been reported.³⁶¹ Insertion into a 2-pyrrolidinone derivative using Me₃SiCH₂N₂ followed by AgCO₂Ph with ultrasound gave a

2-piperidone derivative.³⁶² The copper-catalyzed insertion of a diazo ester into an oxetane gives the ring-expanded tetrahydrofuran derivative.³⁶³ Dirhodium catalyzed insertion into H–C^{sp2} bonds is also known,³⁶⁴ and also H–C^{sp} bonds.³⁶⁵ Insertion of diazoalkane and diazocarbonyl compounds can be catalyzed by copper compounds³⁶⁶ and silver compounds³⁶⁷ as well. Intramolecular insertion reactions are well known, and tolerate a variety of functional groups.³⁶⁸ Intramolecular insertion at the α -carbon of a ketone by a diazoketone, using TiCl₄, gives a bicyclic 1,3-diketone.³⁶⁹ A typical example is the insertion of the diazocarbonyl unit into the C–H bond to give the lactam.³⁷⁰ Similar insertion at the α -carbon of an ether leads to cyclic ethers, with high enantioselectivity when a chiral ligand is used with a rhodium catalyst.³⁷¹ Similar insertion at the α -carbon of silyl ethers has been reported.³⁷² Aryl ketenes react with Me₃SiCHN₂ and then silica to give 2-indanone derivatives.³⁷³

The mechanism³⁷⁴ of the insertion reaction is not known with certainty, but there seem to be at least two possible pathways.

³⁷⁴For a discussion, see Bethell, D. *Adv. Phys. Org. Chem.* **1969**, 7, 153, pp. 190–194.

1. A simple one-step process involving a three-center cyclic transition state:

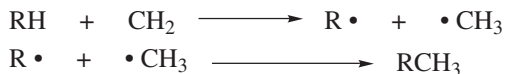

The most convincing evidence for this mechanism is that in the reaction between isobutene-1-¹⁴C and carbene the product 2-methyl-1-butene was labeled only in the 1 position.³⁷⁵ This rules out a free radical or a carbocation or carbanion intermediate. If **41** (or a corresponding ion) were an intermediate, resonance would ensure that some carbene attacked at the 1 position:

Other evidence is that retention of configuration, which is predicted by this mechanism, has been found in a number of instances.³⁷⁶ An ylid intermediate was trapped in the reaction of :CH_2 with allyl alcohol.³⁷⁷

2. A free-radical process in which the carbene directly abstracts a hydrogen from the substrate to generate a pair of free radicals:

One fact supporting this mechanism is that among the products obtained (beside butane and isobutane) on treatment of propane with CH_2 (generated by photolysis of diazomethane and ketene) were propene and ethane,³⁷⁸ which could arise, respectively, by

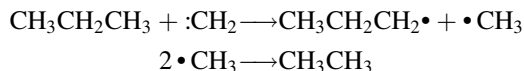

³⁷⁵Doering, W. von E.; Prinzbach, H. *Tetrahedron* **1959**, 6, 24.

³⁷⁸Frey, H.M. *Proc. Chem. Soc.* **1959**, 318.

and

That this mechanism can take place under suitable conditions has been demonstrated by isotopic labeling³⁷⁹ and by other means.³⁸⁰ However, the formation of disproportionation and dimerization products does not always mean that the free-radical abstraction process takes place. In some cases, these products arise in a different manner.³⁸¹ We have seen that the product of the reaction between a carbene and a molecule may have excess energy (p. 288). Therefore it is possible for the substrate and the carbene to react by mechanism 1 (the direct-insertion process) and for the excess energy to cause the compound thus formed to cleave to free radicals. When this pathway is in operation, the free radicals are formed *after* the actual insertion reaction.

The mechanism of cyclopropylcarbene reactions has also been discussed.³⁸²

It has been suggested³⁸³ that singlet carbenes insert by the one-step direct-insertion process and triplets (which, being free radicals, are more likely to abstract hydrogen) by the free-radical process. In support of this suggestion is that CIDNP signals³⁸⁴ (p. 269) were observed in the ethylbenzene produced from toluene and triplet CH_2 , but not from the same reaction with singlet CH_2 .³⁸⁵ Carbenoids (e.g., compounds of the form R_2CMCl , see **12-39**) can insert into a C–H bond by a different mechanism, similar to pathway 2, but involving abstraction of a hydride ion rather than a hydrogen atom.³⁸⁶

An interesting insertion reaction involves EtZnCH_2I and β -keto carbonyl compounds. The reaction of this reagent with *N,N*-dibutyl-3-oxobutanamide, for example, gives the methylene insertion product *N,N*-dibutyl 4-oxopentanamide.³⁸⁷

The reaction in which aldehydes are converted to methyl ketones, $\text{RCHO} + \text{CH}_2\text{N}_2 \rightarrow \text{RCOCH}_3$, while apparently similar, does not involve a free carbene intermediate. It is considered in Chapter 18 (**18-9**).

F. Metal Electrophiles

12-22 Metalation With Organometallic Compounds

Metalation or Metalo-de-hydrogenation

Many organic compounds can be metalated by treatment with an organometallic compound.³⁸⁸ Since the reaction involves a proton transfer, the equilibrium lies on the side of the weaker acid.³⁸⁹ For example, fluorene reacts with butyllithium to give butane and 9-fluoryllithium. Since aromatic hydrocarbons are usually stronger acids than aliphatic ones, R is most often aryl. The most common reagent is butyllithium.³⁹⁰ Normally, only active aromatic rings react with butyllithium. Benzene itself reacts very slowly and in low yield, although benzene can be metalated by butyllithium either in the presence of *t*-BuOK³⁹¹ or by *n*-butyllithium that is coordinated with various diamines.³⁹² Metalation of aliphatic RH is most successful when the carbanions are stabilized by resonance (allylic, benzylic, propargylic,³⁹³ etc.) or when the negative charge is at an *sp* carbon (at triple bonds). Very good reagents for allylic metalation are trimethylsilylmethyl potassium Me₃SiCH₂K³⁹⁴ and a combination of an organolithium compound with a bulky alkoxide (LICKOR superbase).³⁹⁵ The former is also useful for benzylic positions. A combination of BuLi, *t*-BuOK, and tetramethylethylenediamine has been used to convert ethylene to vinylpotassium.³⁹⁶ In certain cases, *gem*-dialkali metal or 1,1,1-trialkali metal compounds can be prepared.³⁹⁷ Examples are the conversion of phenylacetonitrile

to 1,1-dilithiophenylacetonitrile (PhCLi_2CN)³⁹⁸ and propyne to tetralithiopropyne ($\text{Li}_3\text{CC}\equiv\text{CLi}$)³⁹⁹ in each case by treatment with excess butyllithium. The reaction can be used to determine relative acidities of very weak acids by allowing two R-H compounds to compete for the same R'M and to determine which proton in a molecule is the most acidic.⁴⁰⁰

In general, the reaction can be performed only with organometallics of active metals such as lithium, sodium, and potassium, but Grignard reagents abstract protons from a sufficiently acidic C-H bond, as in $\text{R}-\text{C}\equiv\text{C}-\text{H} \rightarrow \text{R}-\text{C}\equiv\text{C}-\text{MgX}$. This is the best method for the preparation of alkynyl Grignard reagents.⁴⁰¹

When a heteroatom, such as N, O, S,⁴⁰² or a halogen,⁴⁰³ is present in a molecule containing an aromatic ring or a double bond, lithiation is usually quite regioselective.⁴⁰⁴ The lithium usually bonds with the sp^2 carbon closest to the heteroatom, probably because the attacking species coordinates with the heteroatom.⁴⁰⁵ Such reactions with compounds such as anisole are often called directed metallations.⁴⁰⁶ In the case of aromatic rings this means attack at the ortho position,⁴⁰⁷ but this is considered in 13-17.

⁴⁰⁸Baldwin, J.E.; Höfle, G.A.; Lever, Jr., O.W. *J. Am. Chem. Soc.* **1974**, *96*, 7125.

In the case of γ,δ -unsaturated disubstituted amides (**42**), the lithium does not go to the closest position, but in this case too the regiochemistry is controlled

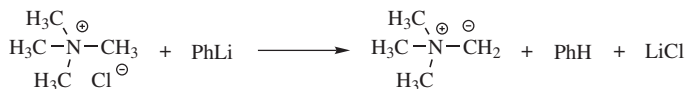

by coordination to the oxygen.⁴⁰⁹

The mechanism involves an attack by R' - (or a polar R') on the *hydrogen*⁴¹⁰ (an acid-base reaction). Evidence is that resonance effects of substituents in R seem to make little difference. When R is aryl, OMe and CF_3 both direct ortho, while isopropyl directs meta and para (mostly meta).⁴¹¹ These results are exactly what would be expected from pure field effects, with no contribution from resonance effects, which implies that attack occurs at the hydrogen and not at R . Other evidence for the involvement of H in the rate-determining step is that there are large isotope effects.⁴¹² The nature of R' also has an effect on the rate. In the reaction between triphenylmethane and $R'Li$, the rate decreased in the order $R' = \text{allyl} > \text{Bu} > \text{Ph} > \text{vinyl} > \text{Me}$, although this order changed with changing concentration of $R'Li$, because of varying degrees of aggregation of the $R'Li$.

With respect to the reagent, this reaction is a special case of **12-24**.

A closely related reaction is formation of nitrogen ylids⁴¹⁴ from quaternary ammonium salts (see **17-8**):

Phosphonium salts undergo a similar reaction (see **16-44**).

12-23 Metalation With Metals and Strong Bases

Metalation or Metalo-de-hydrogenation

Organic compounds can be metalated at suitably acidic positions by active metals and by strong bases.⁴¹⁵ The reaction has been used to study the acidities of very weak acids (see p. 250). The conversion of terminal alkynes to acetylid ions is one important application.⁴¹⁶ Synthetically, an important use of the method is to convert aldehydes and ketones,⁴¹⁷ carboxylic esters, and similar compounds to their enolate forms,⁴¹⁸ for example,

for use in nucleophilic substitutions (**10-67**, **10-68**, and **13-14**) and in additions to multiple bonds (**15-24** and **16-53**). It has been shown that lithiation with lithium amides can also be regioselective (see **12-22**).⁴¹⁹ Lithium enolates exist as aggregates in solution.⁴²⁰ For very weak acids, the most common reagents for synthetic purposes are lithium amides, especially LDA, which has the structure $(i\text{Pr})_2\text{NLi}$.⁴²¹ The mechanism for this deprotonation reaction has been studied,⁴²² as has the rate of deprotonation.⁴²³

METALS AS LEAVING GROUPS

A. Hydrogen as the Electrophile

12-24 Replacement of Metals by Hydrogen

Hydro-de-metallation or Demetallation

Organometallic compounds, including enolate anions, react with acids in reactions in which the metal is replaced by hydrogen.⁴²⁴ The R group may be aryl (see **11-41**). The reaction is often used to introduce deuterium or tritium into susceptible positions. For Grignard reagents, water is usually a strong enough acid, but stronger acids are also used. An important method for the reduction of alkyl halides consists of the process $\text{RX} \rightarrow \text{RMgX} \rightarrow \text{RH}$.

Other organometallic compounds that are hydrolyzed by water are those of sodium, potassium, lithium, zinc, and so on, the ones high in the electromotive series. Enantioselective protonation of lithium enolates⁴²⁵ and cyclopropyllithium compounds⁴²⁶ have been reported. When the metal is less active, stronger acids are required. For example, R_2Zn compounds react explosively with water, R_2Cd slowly, and R_2Hg not at all, although the latter can be cleaved with concentrated HCl. However, this general statement has many exceptions, some hard to explain. For example, BR_3 compounds are completely inert to water, and GaR_3 at room temperature cleave just one R group, but AlR_3 react violently with water. However, BR_3 can be converted to RH with carboxylic acids.⁴²⁷ For less active metals it is often possible to cleave just one R group from a multivalent metal. For example,

Organometallic compounds of less active metals and metalloids (e.g., silicon,⁴²⁸ antimony, and bismuth, are quite inert to water. Organomercury compounds (RHgX or R_2Hg) can be reduced to RH by H_2 , NaBH_4 , or other reducing agents.⁴²⁹ The reduction with NaBH_4 takes place by a free-radical mechanism.⁴³⁰ Alkyl-Si

12-25 The Reaction between Organometallic Reagents and Oxygen⁴³²

Hydroperoxy-de-metalation; Hydroxy-de-metalation

Oxygen reacts with Grignard reagents to give either hydroperoxides⁴³³ or alcohols. The reaction can be used to convert alkyl halides to alcohols without side reactions. With aryl Grignard reagents yields are lower and only phenols are obtained, not hydroperoxides. Because of this reaction, oxygen should be excluded when Grignard reagents are prepared and used in various reactions.

Most other organometallic compounds also react with oxygen. Trialkylboranes and alkyldichloroboranes RBCl_2 can be conveniently converted to hydroperoxides by treatment with oxygen followed by hydrolysis.⁴³⁴ Dilithiated carboxylic acids (see 10-70) react with oxygen to give (after hydrolysis) α -hydroxy carboxylic acids.⁴³⁵ There is evidence that the reaction between Grignard reagents and oxygen involves a free-radical mechanism.⁴³⁶

The 1,1-dimetallc compounds $\text{R}_2\text{C}(\text{SnMe}_3)\text{ZnBr}$ were oxidized by dry air at -10 to 0°C in the presence of Me_3SiCl to give aldehydes or ketones $\text{R}_2\text{C}=\text{O}$.⁴³⁷

12-26 Reaction between Organometallic Reagents and Peroxides

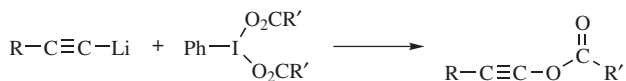

tert-Butoxy-de-metalation

A convenient method of preparation of *tert*-butyl ethers consists of treating Grignard reagents with *tert*-butyl acyl peroxides.⁴³⁸ Both alkyl and aryl Grignard reagents can be used. The application of this reaction to Grignard reagents prepared from cyclopropyl halides permits cyclopropyl halides to be converted to *tert*-butyl ethers of cyclopropanols,⁴³⁹ which can then be easily hydrolyzed to the cyclopropanols. The direct conversion of cyclopropyl halides to cyclopropanols by **10-1** is not generally feasible, because cyclopropyl halides do not generally undergo nucleophilic substitutions without ring opening.

Vinylic lithium reagents (**43**) react with silyl peroxides to give high yields of silyl enol ethers with retention of configuration.⁴⁴⁰ Since the preparation of **43** from vinylic halides

(**12-39**) also proceeds with retention, the overall procedure is a method for the stereospecific conversion of a vinylic halide to a silyl enol ether. In a related reaction, alkynyl esters can be prepared from lithium acetylides and phenyliodine(III) dicarboxylates.⁴⁴¹

The reaction of alkenes with borane, monoalkyl and dialkylboranes leads to a new organoborane (see **15-16**). Treatment of organoboranes with alkaline H_2O_2 oxidizes trialkylboranes to esters of boric acid.⁴⁴² This reaction does not affect double or triple bonds, aldehydes, ketones, halides, or nitriles that may be present elsewhere in the molecule. There is no rearrangement of the R group itself, and this reaction is a step in the hydroboration method of converting alkenes to alcohols (**15-16**). The mechanism has been formulated as involving initial formation of an ate complex when the hydroperoxide anion attacks the electrophilic boron atom. Subsequent rearrangement from boron to oxygen,⁴⁴² as shown, leads to the B–O–R unit.

Similar migration of the other two R groups and hydrolysis of the B–O bonds leads to the alcohol and boric acid. Retention of configuration is observed in R. Boranes can also be oxidized to borates in good yields with oxygen,⁴⁴³ with sodium perborate NaBO_3 ,⁴⁴⁴ and with trimethylamine oxide, either anhydrous⁴⁴⁵ or in the form of the dihydrate.⁴⁴⁶ The reaction with oxygen is free radical in nature.⁴⁴⁷

reaction, **13-12**) is probably the most notable example. A simple synthesis involve the reaction of a Grignard reagent, such as phenylmagnesium bromide with an alkyl borate to give phenylboronic acid.⁴⁴⁸ Alkylboronic acids are similarly prepared.⁴⁴⁹ Note that boronic acids are subject to cyclic trimerization with loss of water to form boroxines. Trimethylborate, $B(OMe)_3$, can be used in place of tri-*n*-butyl borate.⁴⁵⁰ Newer methods involve the palladium-mediated borylation of alcohols with bis(pinacolato)diboron⁴⁵¹ or pinacolborane,⁴⁵² but deprotection of the boronate esters can be a problem. Diolboranes, such as catecholborane **44**,⁴⁵³ are prepared by the reaction of a diol with borane. Cedranediolborane (**45**, prepared from the cedrane-8,9-diol⁴⁵⁴ by treatment with borane•dimethyl sulfide) can be coupled to aryl iodides with a palladium catalyst, and generates the free boronic acid by treatment with diethanolamine and then aqueous acid.⁴⁵⁵ Boronate esters are often prepared as a means to purify the organoboron species, but some of these esters are hydrolytically unstable and difficult to deal with upon completion of the reaction.⁴⁵⁶

Alkeneboronic esters and acids are also readily available, as in the addition of vinylmagnesium chloride⁴⁵⁷ to trimethyl borate below $-50^\circ C$, followed by hydrolysis.⁴⁵⁸

A nonaqueous workup procedure has been reported for the preparation of arylboronic esters [$\text{ArB}(\text{OR}'_2)$].⁴⁵⁹ Uncontrollable polymerization or oxidation of much of the boronic acid occurred during the final stages of the isolation procedure, but could be avoided by *in situ* conversion to the dibutyl ester by adding the crude product to 1-butanol. The samarium(III)-catalyzed hydroboration of olefins with catecholborane is a good synthesis of boronate esters.⁴⁶⁰

Trialkyl borates (called orthoborates) can be prepared by heating the appropriate alcohol with boron trichloride in a sealed tube, but the procedure works well only for relatively simple alkyl groups.⁴⁶¹ Heating alcohols with boron trioxide (B_2O_3) in an autoclave at 110–170°C give the trialkyl borate.⁴⁶² Boric acid can be used for the preparation of orthoborates⁴⁶³ by heating with alcohols in the presence of either hydrogen chloride or concentrated sulfuric acid. Removal of water as an azeotrope with excess alcohol improves the yield,⁴⁶⁴ and good yields can be obtained for trialkyl borates⁴⁶⁵ and even for triphenyl borate.⁴⁶⁶ This method is unsuccessful for those borates whose parent alcohols do not form azeotropes with water and for the tertiary alkyl borates,⁴⁶⁷ impure samples are usually obtained.⁴⁶⁸

Potassium organotrifluoroborates (RBF_3K) are readily prepared by the addition of inexpensive KHF_2 to a variety of organoboron intermediates.⁴⁶⁹ They are monomeric, crystalline solids that are readily isolated and indefinitely stable in the air. These reagents can be used in several of the applications where boronic acids or esters are used (13-10–13-13).⁴⁷⁰ Note that vinylboronic acid and even vinylboronate esters are unstable to polymerization,⁴⁷¹ whereas the analogous vinyltrifluoroborate is readily synthesized and completely stable.⁴⁷²

D. Halogen Electrophiles

12-31 Halo-de-metalation

Grignard reagents react with halogens to give alkyl halides. The reaction is useful for the preparation of iodo compounds from the corresponding chloro or bromo compounds. The reaction is not useful for preparing chlorides, since the reagents RMgBr and RMgI react with Cl₂ to give mostly RBr and RI, respectively.⁴⁸¹

Most organometallic compounds, both alkyl and aryl, also react with halogens to give alkyl or aryl halides.⁴⁸² The reaction can be used to convert acetylide ions to 1-haloalkynes.⁴⁸³ Since acetylide ions are easily prepared from alkynes (**12-23**), this provides a means of accomplishing the conversion RC≡CH → RC≡CX. Vinylidonium tetrafluoroborates were converted to vinyl fluorides by heating.⁴⁸⁴ Similarly, vinyl trifluoroborates were converted to the vinyl iodide with NaI and chloramine-T in aq. THF.⁴⁸⁵ The reaction of an alkene with CuO•BF₄, iodine and triethylsilane gave the 2-iodo alkane.⁴⁸⁶

Trialkylboranes react rapidly with I₂⁴⁸⁷ or Br₂⁴⁸⁸ in the presence of NaOMe in methanol, or with FeCl₃ or other reagents⁴⁸⁹ to give alkyl iodides, bromides, or chlorides, respectively. Combined with the hydroboration reaction (**15-16**), this is an indirect way of adding HBr, HI, or HCl to a double bond to give products with an

anti-Markovnikov orientation (see **15-1**). Trialkylboranes can also be converted to alkyl iodides by treatment with allyl iodide and air in a free-radical process.⁴⁹⁰ *trans*-1-Alkenylboronic acids **47**, prepared by hydroboration of terminal alkynes with catecholborane to give **46**⁴⁹¹ (**15-16**), followed by hydrolysis, react with I₂ in the presence of NaOH at 0°C in ethereal solvents to give *trans* vinylic iodides.⁴⁹² Treatment with ICl also gives the vinylic iodide.⁴⁹³ This is an indirect way of accomplishing the anti-Markovnikov addition of HI to a

terminal triple bond. The reaction cannot be applied to alkenylboronic acids prepared from internal alkynes. However, alkenylboronic acids prepared from both internal and terminal alkynes react with Br₂ (2 equivalents of Br₂ must be used) followed by base to give the corresponding vinylic bromide, but in this case with *inversion* of configuration; so the product is the *cis* vinylic bromide.⁴⁹⁴ Alkenylboronic acids also give vinylic bromides and iodides when treated with a mild oxidizing agent and NaBr or NaI, respectively.⁴⁹⁵ Treatment of **47** (prepared from terminal alkynes) with Cl₂ gave vinylic chlorides with inversion.⁴⁹⁶ Vinylic boranes can be converted to the corresponding vinylic halide by treatment with NCS or NBS.⁴⁹⁷ Vinylic halides can also be prepared from vinylic silanes⁴⁹⁸ and from vinylic copper reagents. The latter react with I₂ to give iodides,⁴⁹⁹ and with NCS or NBS at -45°C to give chlorides or bromides.⁵⁰⁰ T

For the reaction of lithium enolate anions of esters with I₂ or CX₄, see **12-5**.

The conversion of terminal alkynes to 1-iodo-1-alkynes was reported using NaI under electrochemical conditions.⁵⁰¹ The reaction of an aryl alkyne with HInCl₂/BEt₃,

and then iodine leads to a *Z*-vinyl iodide with respect to the aryl group and the iodine atom.⁵⁰² 1-Bromo-1-alkynes were converted to the 1-iodo-1-alkyne with CuI.⁵⁰³

It is unlikely that a single mechanism suffices to cover all conversions of organometallic compounds to alkyl halides.⁵⁰⁴ In a number of cases, the reaction has been shown to involve inversion of configuration (see p. 757), indicating an S_E2 (back) mechanism, while in other cases retention of configuration has been shown,⁵⁰⁵ implicating an S_E2 (front) or S_Ei mechanism. In still other cases, complete loss of configuration as well as other evidence have demonstrated the presence of a free-radical mechanism.^{505,506}

E. Nitrogen Electrophiles

12-32 The Conversion of Organometallic Compounds to Amines

Amino-de-metalation

There are several methods for conversion of alkyl- or aryllithium compounds to primary amines.⁵⁰⁷ The two most important are treatment with hydroxylamine derivatives and with certain azides.⁵⁰⁸ In the first of these methods, treatment of RLi with methoxyamine and MeLi in ether at -78°C gives RNH₂.⁵⁰⁹ Grignard reagents from aliphatic halides give lower yields. The reaction can be extended to give secondary amines by the use of *N*-substituted methoxyamines (CH₃ONHR').⁵¹⁰ There is evidence⁵¹¹ that the mechanism involves the direct displacement of OCH₃ by R

on an intermediate $\text{CH}_2\text{ONR}'^-(\text{CH}_3\text{ONR}'^- \text{Li}^+ + \text{RLi} \rightarrow \text{CH}_3\text{OLi} + \text{RNR}'^- \text{Li}^+)$. The most useful azide is tosyl azide TsN_3 .⁵¹² The initial product is usually RNH_2 , but this is easily reducible to the amine (**19-51**). With some azides, such as azidomethyl phenyl sulfide (PhSCH_2N_3), the group attached to the N_3 is a poor leaving group, so the initial product is a triazene (in this case $\text{ArNHN}=\text{NCH}_2\text{Sph}$ from ArMgX), which can be hydrolyzed to the amine.⁵¹³

Organoboranes react with a mixture of aqueous NH_3 and NaOCl to produce primary amines.⁵¹⁴ It is likely that the actual reagent is chloramine (NH_2Cl). Chloramine itself,⁵¹⁵ hydroxylamine-*O*-sulfonic acid in diglyme,⁵¹⁶ and trimethylsilyl azide⁵¹⁷ also give the reaction. Since the boranes can be prepared by the hydroboration of alkenes (**15-16**), this is an indirect method for the addition of NH_3 to a double bond with anti-Markovnikov orientation. Secondary amines can be prepared⁵¹⁸ by the treatment of alkyl- or aryl-dichloroboranes or dialkylchloroboranes with alkyl or aryl azides.

The use of an optically active R^*BCl_2 gave secondary amines of essentially 100% optical purity.⁵¹⁹ Aryllead triacetates, $\text{ArPb}(\text{OAc})_3$, give secondary amines (ArNHR') when treated with primary aromatic amines $\text{Ar}'\text{NH}_2$ and $\text{Cu}(\text{OAc})_2$.⁵²⁰

Secondary amines have been converted to tertiary amines by treatment with lithium dialkylcuprate reagents: $\text{R}_2\text{CuLi} + \text{NHR} \rightarrow \text{RNR}_2$.⁵²¹ The reaction was also used to convert primary amines to secondary, but yields were lower.⁵²²

In the presence of a CuI catalyst, acetamide reacted with vinyl iodides to give the corresponding enamide, where the nitrogen of the amide replaced the iodine atom.⁵²³

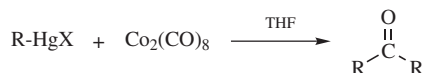

Terminal alkynes reacted with chlorodiphenylphosphine (Ph₂PCl) and a nickel catalyst to give the 1-diphenylphosphino alkyne (R-C≡C-PPh₂).⁵²⁴ Alkynyl halides can be used for a similar reaction. Treatment of methyl carbamates with KHMDS and CuI, followed by two equivalents of 1-bromo phenylacetylene gave the *N*-substituted alkyne, Ph-C≡C-N(CO₂Me)R.⁵²⁵

OS VI, 943.

F. Carbon Electrophiles

12-33 The Conversion of Organometallic Compounds to Ketones, Aldehydes, Carboxylic Esters, or Amides

Acyl-de-metalation, and so on

Symmetrical ketones⁵²⁶ can be prepared in good yields by the reaction of organomercuric halides⁵²⁷ with dicobalt octacarbonyl in THF,⁵²⁸ or with nickel carbonyl in DMF or certain other solvents.⁵²⁹ The R group may be aryl or alkyl. However, when R is alkyl, rearrangements may intervene in the CO₂(CO)₈ reaction, although the Ni(CO)₄ reaction seems to be free from such rearrangements.⁵³⁰ Divinyl ketones (useful in the Nazarov cyclization, **15-20**) have been prepared in high yields by treatment of vinylic mercuric halides with CO and a rhodium catalyst.⁵³⁰ In a more general synthesis of unsymmetrical ketones, tetraalkyltin compounds (R₄Sn) are treated with a halide R'X (R' = aryl, vinylic, benzylic), CO, and a Pd complex catalyst.⁵³¹ Similar reactions use Grignard reagents, Fe(CO)₅, and an alkyl halide.⁵³² Cyclobutanone derivatives were prepared by carbonylation (treatment with CO) of a cyclic titanium compound.⁵³³

Grignard reagents react with formic acid to give good yields of aldehydes. Two equivalents of RMgX are used; the first converts HCOOH to HCOO⁻, which reacts

OS IX, 548

G. Metal Electrophiles**12-35** Transmetalation With a Metal**Metallo-de-metalation**

Many organometallic compounds are best prepared by this reaction, which involves replacement of a metal in an organometallic compound by another metal. The RM' compound can be successfully prepared only when M' is above M in the electromotive series, unless some other way is found to shift the equilibrium. That is, RM is usually an unreactive compound and M' is a metal more active than M . Most often, RM is R_2Hg , since mercury alkyls⁵²⁷ are easy to prepare and mercury is far down in the electromotive series.⁵⁴⁹ Alkyls of Li, Na, K, Be, Mg, Al, Ga, Zn, Cd, Te, Sn, and so on have been prepared this way. An important advantage of this method over **12-38** is that it ensures that the organometallic compound will be prepared free of any possible halide. This method can be used for the isolation of solid sodium and potassium alkyls.⁵⁵⁰ If the metals lie too close together in the series, it may not be possible to shift the equilibrium. For example, alkylbismuth compounds cannot be prepared in this way from alkylmercury compounds.

12-36 Transmetalation With a Metal Halide

Metallo-de-metalation

In contrast to **12-35**, the reaction between an organometallic compound and a metal *halide* is successful only when M' is *below* M in the electromotive series.⁵⁵¹ The two reactions considered together therefore constitute a powerful tool for preparing all kinds of organometallic compounds. In this reaction, the most common substrates are Grignard reagents and organolithium compounds.⁵⁵²

The MgX of Grignard reagents⁵⁵³ can migrate to terminal positions in the presence of small amounts of TiCl_4 .⁵⁵⁴ The proposed mechanism consists of metal exchange (**12-36**), elimination–addition, and metal exchange:

The addition step is similar to **15-16** or **15-17** and follows Markovnikov's rule, so the positive titanium goes to the terminal carbon.

Among others, alkyls of Be, Zn,⁵⁵⁵ Cd, Hg, Al, Sn, Pb, Co, Pt, and Au have been prepared by treatment of Grignard reagents with the appropriate halide.⁵⁵⁶ The reaction has been used to prepare alkyls of almost all nontransition metals and even of some transition metals. Alkyls of metalloids and of nonmetals, including

⁵⁵¹For reviews of the mechanism, see Abraham, M.H.; Grellier, P.L. in Hartley, F.R.; Patai, S. *The Chemistry of the Carbon–Metal Bond*, Vol. 2, Wiley, NY, pp. 25–149; Abraham, M.H. *Comprehensive Chemical Kinetics*, Bamford, C.H.; Tipper, C.F.H., Eds., Vol. 12; Elsevier, NY, **1973**, pp. 39–106; Jensen, F.R.; Rickborn, B. *Electrophilic Substitution of Organomercurials*, McGraw-Hill, NY, **1968**, pp. 100–192. ⁵⁵⁶For a review, see Noltes, J.G. *Bull. Soc. Chim. Fr.* **1972**, 2151.

Si, B,⁵⁵⁷ Ge, P, As, Sb, and Bi, can also be prepared in this manner.⁵⁵⁸ Except for alkali-metal alkyls and Grignard reagents, the reaction between RM and M'X is the most common method for the preparation of organometallic compounds.⁵⁵⁹

Lithium dialkylcopper reagents can be prepared by mixing 2 equivalents of RLi with 1 equivalent of a cuprous halide in ether at low temperatures:⁵⁶⁰

Another way is to dissolve an alkylcopper compound in an alkyllithium solution. Higher order cuprates can also be prepared, as well as “non-ate” copper reagents.⁵⁶¹

Metalloenes (**48**, see p. 66) are usually made by this method:

Among others, metallocenes of Sc, Ti, V, Cr, Mn, Fe, Co, and Ni have been prepared in this manner.⁵⁶²

Metal nitrates are sometimes used instead of halides.

In a related reaction sulfurated boranes ($\text{R}_2\text{B-SSiR}'_2$) react with Grignard reagents, such as methylmagnesium bromide to give the B-alkyl borane (e.g., $\text{R}_2\text{B-Me}$) upon heating *in vacuo*.⁵⁶³

12-37 Transmetalation With an Organometallic Compound

Metallo-de-metalation

This type of metallic exchange is used much less often than 12-35 and 12-36. It is an equilibrium reaction and is useful only if the equilibrium lies in the desired direction. Usually the goal is to prepare a lithium compound that is not prepared easily in other ways,⁵⁶⁴ for example, a vinylic or an allylic lithium, most commonly from an organotin substrate. Examples are the preparation of vinylolithium from phenyllithium and tetravinyltin and the formation of α -dialkylamino organolithium compounds from the corresponding organotin compounds⁵⁶⁵

The reaction has also been used to prepare 1,3-dilithiopropanes⁵⁶⁶ and 1,1-dilithiomethylenecyclohexane⁵⁶⁷ from the corresponding mercury compounds. In general, the equilibrium lies in the direction in which the more electropositive metal is bonded to that alkyl or aryl group that is the more stable carbanion (p. 250). The reaction proceeds with retention of configuration;⁵⁶⁸ an S_{Ei} mechanism is likely.⁵⁶⁹

“Higher order” cuprates⁵⁷⁰ (see 10-58) have been produced by this reaction starting with a vinylic tin compound:⁵⁷¹

These compounds are not isolated, but used directly *in situ* for conjugate addition reactions (**15-25**). Another method for the preparation of such reagents (but with Zn instead of Li) allows them to be made from α -acetoxy halides:⁵⁷²

OS V, 452; VI, 815; VIII, 97.

HALOGEN AS LEAVING GROUP

The reduction of alkyl halides can proceed by an electrophilic substitution mechanism, but it is considered in Chapter 19 (**19-53**).

12-38 Metalo-de-halogenation

Alkyl halides react directly with certain metals to give organometallic compounds.⁵⁷³ The most common metal is magnesium, and of course this is by far the most common method for the preparation of Grignard reagents.⁵⁷⁴ The order of halide activity is $\text{I} > \text{Br} > \text{Cl}$. The reaction can be applied to many alkyl halides primary, secondary, and tertiary and to aryl halides, although aryl *chlorides* require the use of THF or another higher boiling solvent instead of the usual ether, or special entrainment methods.⁵⁷⁵ Aryl iodides and bromides can be treated in the usual manner. Allylic Grignard reagents can also be prepared in the usual manner (or in THF),⁵⁷⁶ although in the presence of excess halide these may give Wurtz-type coupling products (see **10-56**).⁵⁷⁷ Like aryl chlorides, vinylic halides require higher boiling solvents (see OS IV, 258). A good procedure for benzylic and allylic halides is to use magnesium anthracene (prepared from Mg and anthracene in THF)⁵⁷⁸

instead of ordinary magnesium,⁵⁷⁹ although activated magnesium turnings have also been used.⁵⁸⁰ Alkynyl Grignard reagents are not generally prepared by this method at all. For these, **12-22** is used. Grignard reagents can also be formed from an alkyl halide and 1,2-dibromoethane with iodine as an initiator.⁵⁸¹

Dihalides⁵⁸² can be converted to Grignard reagents if the halogens are different and are at least three carbons apart. If the halogens are the same, it is possible to obtain dimagnesium compounds (e.g., $\text{BrMg}(\text{CH}_2)_4\text{MgBr}$).⁵⁸³ 1,2-Dihalides give elimination⁵⁸⁴ instead of Grignard reagent formation (**17-22**), and the reaction is seldom successful with 1,1-dihalides, although the preparation of *gem*-disubstituted compounds, such as $\text{CH}_2(\text{MgBr})_2$, has been accomplished with these substrates.⁵⁸⁵ α -halo Grignard reagents and α -halolithium reagents can be prepared by the method given in **12-39**.⁵⁸⁶ Alkylmagnesium fluorides can be prepared by refluxing alkyl fluorides with Mg in the presence of appropriate catalysts (e.g., I_2 or EtBr) in THF for several days.⁵⁸⁷ Nitrogen-containing Grignard reagents have been prepared.⁵⁸⁸

The presence of other functional groups in the halide usually affects the preparation of the Grignard reagent. Groups that contain active hydrogen (defined as any hydrogen that will react with a Grignard reagent), such as OH, NH_2 , and COOH, can be present in the molecule, but only if they are converted to the salt form (O^- , NH^- , COO^- , respectively). Groups that react with Grignard reagents, such as $\text{C}=\text{O}$, $\text{C}\equiv\text{N}$, NO_2 , COOR, inhibit Grignard formation entirely. In general, the only functional groups that may be present in the halide molecule without any interference at all are double and triple bonds (except terminal triple bonds) and OR and NR_2 groups. However, β -halo ethers generally give β elimination when treated with

magnesium (see **17-24**), and Grignard reagents from α -halo ethers⁵⁸⁹ can only be formed in THF or dimethoxymethane at a low temperature, for example,⁵⁹⁰

because such reagents immediately undergo a elimination (see **12-39**) at room temperature in ether solution.

Because Grignard reagents react with water (**12-24**) and with oxygen (**12-25**), it is generally best to prepare them in an anhydrous nitrogen atmosphere. Grignard reagents are generally neither isolated nor stored; solutions of Grignard reagents are used directly for the required synthesis. Grignard reagents can also be prepared in benzene or toluene, if a tertiary amine is added to complex with the RMgX .⁵⁹¹ This method eliminates the need for an ether solvent. With certain primary alkyl halides it is even possible to prepare alkylmagnesium compounds in hydrocarbon solvents in the absence of an organic base.⁵⁹² It is also possible to obtain Grignard reagents in powdered form, by complexing them with the chelating agent tris(3,6-dioxahexyl)amine, $\text{N}(\text{CH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{OCH}_3)_3$.⁵⁹³

Next to the formation of Grignard reagents, the most important application of this reaction is the conversion of alkyl and aryl halides to organolithium compounds,⁵⁹⁴ but it has also been carried out with many other metals (e.g., Na, Be, Zn, Hg, As, Sb, and Sn). With sodium, the Wurtz reaction (**10-56**) is an important side reaction. In some cases where the reaction between a halide and a metal is too slow, an alloy of the metal with potassium or sodium can be used instead. The most important example is the preparation of tetraethyl lead from ethyl bromide and a Pb–Na alloy.

The efficiency of the reaction can often be improved by use of the metal in its powdered⁵⁹⁵ or vapor⁵⁹⁶ form. These techniques have permitted the preparation of some organometallic compounds that cannot be prepared by the standard

procedures. Among the metals produced in an activated form are Mg,⁵⁹⁷ Ca,⁵⁹⁸ Zn,⁵⁹⁹ Al, Sn, Cd,⁶⁰⁰ Ni, Fe, Ti, Cu,⁶⁰¹ Pd, and Pt.⁶⁰²

The mechanism of Grignard reagent formation involves free radicals,⁶⁰³ and there is much evidence for this, from CIDNP⁶⁰⁴ (p. 269) and from stereochemical, rate, and product studies.⁶⁰⁵ Further evidence is that free radicals have been trapped,⁶⁰⁶ and that experiments that studied the intrinsic reactivity of MeBr on a magnesium single-crystal surface showed that Grignard reagent formation does not take place by a single-step insertion mechanism.⁶⁰⁷ The following SET mechanism has been proposed:⁶⁰⁴

Other evidence has been offered to support a SET-initiated radical process for the second step of this mechanism.⁶⁰⁸ The species $\text{R-X}^{\cdot-}$ and $\text{Mg}_s^{\cdot+}$ are radical ions.⁶⁰⁹ The subscript "s" is meant to indicate that the species so marked are bound to the surface of the magnesium. It is known that this is a surface reaction.⁶¹⁰ It has been suggested that some of the R^{\cdot} radicals diffuse from the magnesium surface into the solution and then return to the surface to react with the XMg_s^{\cdot} . There is evidence

both for⁶¹¹ and against⁶¹² this suggestion. Another proposal is that the fourth step is not the one shown here, but that the R• is reduced by Mg⁺ to the carbanion R⁻, which combines with MgX⁺ to give RMgX.⁶¹³

There are too many preparations of Grignard reagents in *Organic Syntheses* for us to list here. Chiral Grignard reagents are rare, since they are configurationally unstable in most cases. However, a few chiral Grignard reagents are known.⁶¹⁴ Use of the reaction to prepare other organometallic compounds can be found in OS I, 228; II, 184, 517, 607; III, 413, 757; VI, 240; VII, 346; VIII, 505. The preparation of unsolvated butylmagnesium bromide is described at OS V, 1141. The preparation of highly reactive (powdered) magnesium is given at OS VI, 845.

12-39 Replacement of a Halogen by a Metal from an Organometallic Compound

Metallo-de-halogenation

The exchange reaction between halides and organometallic compounds occurs most readily when M is lithium and X is bromide or iodide,⁶¹⁵ although it has been shown to occur with magnesium.⁶¹⁶ The R' group is usually, although not always, alkyl, and often butyl; R is usually aromatic.⁶¹⁷ Alkyl halides are generally not reactive enough, while allylic and benzylic halides usually give Wurtz coupling. Of course, the R that becomes bonded to the halogen is the one for which RH is the weaker acid. Despite the preponderance of reactions with bromides and iodides, it is noted that the reaction of 1-fluorooctane with 4–10 equivalents of lithium powder and 2–4 equivalents of DTBB (4,4'-di-*tert*-butylbiphenyl) in THP at 0°C for 5 min, was shown to give a solution of the corresponding 1-octyllithium.⁶¹⁸ Vinylic halides react with retention of configuration.⁶¹⁹ The

reaction can be used to prepare α -halo organolithium and α -halo organomagnesium compounds,⁶²⁰ for example,⁶²¹

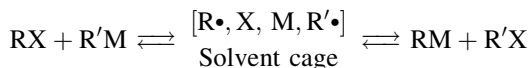

Such compounds can also be prepared by hydrogen-metal exchange, for example,⁶²²

This is an example of **12-22**. However, these α -halo organometallic compounds are stable (and configurationally stable as well⁶²³) only at low temperatures (ca. -100°C) and only in THF or mixtures of THF and other solvents (e.g., HMPA). At ordinary temperatures they lose MX (α elimination) to give carbenes (which then react further) or carbenoid reactions. The α -chloro- α -magnesium sulfones $\text{ArSO}_2\text{CH}(\text{Cl})\text{MgBr}$ are exceptions, being stable in solution at room temperature and even under reflux.⁶²⁴ Compounds in which a halogen and a transition metal are on the same carbon can be more stable than the ones with lithium.⁶²⁵

There is evidence that the mechanism⁶²⁶ of the reaction of alkyllithium compounds with alkyl and aryl iodides involves free radicals.⁶²⁷

Among the evidence is the fact that coupling and disproportionation products are obtained from $\text{R}\cdot$ and $\text{R}'\cdot$ and the observation of CIDNP.^{627,628} However, in the degenerate exchange between PhI and PhLi the ate complex $\text{Ph}_2\text{I}^- \text{Li}^+$ has been

shown to be an intermediate,⁶²⁹ and there is other evidence that radicals are not involved in all instances of this reaction.⁶³⁰

In a completely different kind of process, alkyl halides can be converted to certain organometallic compounds by treatment with organometalate ions, for example,

Most of the evidence is in accord with a free-radical mechanism involving electron transfer, although an $\text{S}_{\text{N}}2$ mechanism can compete under some conditions.⁶³¹

CARBON LEAVING GROUPS

In these reactions (12-40–12-48), a carbon–carbon bond cleaves. We regard as the substrate the side that retains the electron pair; hence the reactions are considered electrophilic substitutions. The incoming group is hydrogen in all but one (12-42) of the cases. The reactions in groups A and B are sometimes called *anionic cleavages*,⁶³² although they do not always occur by mechanisms involving free carbanions ($\text{S}_{\text{E}}1$). When they do, the reactions are facilitated by increasing stability of the carbanion.

A. Carbonyl-Forming Cleavages

These reactions follow the pattern

The leaving group is stabilized because the electron deficiency at its carbon is satisfied by a pair of electrons from the oxygen. With respect to the leaving group the reaction is elimination to form a $\text{C}=\text{O}$ bond. Retrograde aldol reactions (16-34) and cleavage of cyanohydrins (16-52) belong to this classification but are treated in Chapter 16 under their more important reverse reactions. Other eliminations to form $\text{C}=\text{O}$ bonds are discussed in Chapter 17 (17-32).

12-40 Decarboxylation of Aliphatic Acids

Hydro-de-carboxylation

TABLE 12.2. Some Acids that Undergo Decarboxylation Fairly Readily^a

	Acid Type	Decarboxylation Product
Malonic		
α -Cyano		
α -Nitro		
α -Aryl		
α,α,α -Trihalo	$X_3C-COOH$	X_3C-H
β -Keto		
β,γ -Unsaturated		

^aOthers are described in the text.

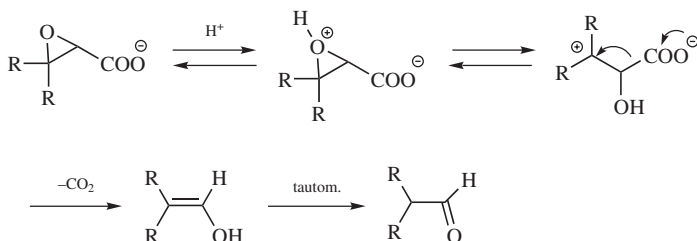

Many carboxylic acids can be successfully decarboxylated, either as the free acid or in the salt form, but not simple fatty acids.⁶³³ An exception is acetic acid, which as the acetate, heated with base, gives good yields of methane. Malonic acid derivatives are the most common substrates for decarboxylation, giving the corresponding monocarboxylic acid. Decarboxylation of 2-substituted malonic acids has been reported using microwave irradiation.⁶³⁴ Aliphatic acids that do undergo successful decarboxylation have certain functional groups or double or triple bonds in the α or β position. Some of these are shown in Table 12.2. For decarboxylation of aromatic acids, see **11-35**. Decarboxylation of an α -cyano acid can give a nitrile or a carboxylic acid, since the cyano group may or may not be hydrolyzed in the course of the reaction. In addition to the compounds listed in Table 12.2, decarboxylation can also be carried out on α,β -unsaturated and α,β -acetylenic acids. α,β -Unsaturated acids can also be decarboxylated⁶³⁵ with copper

and quinoline in a manner similar to that discussed in **11-35**. Glycidic acids give aldehydes on decarboxylation. The following mechanism has been suggested:⁶³⁶

The direct product is an enol that tautomerizes to the aldehyde.⁶³⁷ This is the usual last step in the Darzens reaction (**16-40**).

Decarboxylations can be regarded as reversals of the addition of carbanions to carbon dioxide (**16-82**), but free carbanions are not always involved.⁶³⁸ When the carboxylate *ion* is decarboxylated, the mechanism can be either S_E1 or S_E2. In the case of the S_E1 mechanism, the reaction is of course aided by the presence of electron-withdrawing groups, which stabilize the carbanion.⁶³⁹ Decarboxylations of carboxylate ions can be accelerated by the addition of a suitable crown ether, which in effect removes the metallic ion.⁶⁴⁰ The reaction without the metallic ion has also been performed in the gas phase.⁶⁴¹ But some acids can also be decarboxylated directly and, in most of these cases, there is a cyclic, six-center mechanism:

Here too there is an enol that tautomerizes to the product. The mechanism is illustrated for the case of β -keto acids,⁶⁴² but it is likely that malonic acids, α -cyano acids, α -nitro acids, and β,γ -unsaturated acids⁶⁴³ behave similarly,

since similar six-membered transition states can be written for them. Some α,β -unsaturated acids are also decarboxylated by this mechanism by isomerizing to the β,γ -isomers before they

actually decarboxylate.⁶⁴⁴ Evidence is that **49** and similar bicyclic β -keto acids resist decarboxylation.⁶⁴⁵ In such compounds, the six-membered cyclic transition state cannot form for steric reasons, and if it could, formation of the intermediate enol would violate Bredt's rule (p. 229).⁶⁴⁶ Some carboxylic acids that cannot form a six-membered transition state can still be decarboxylated, and these presumably react through an S_E1 or S_E2 mechanism.⁶⁴⁷ Further evidence for the cyclic mechanism is that the reaction rate varies very little with a change from a nonpolar to a polar solvent (even from benzene to water⁶⁴⁸), and is not subject to acid catalysis.⁶⁴⁹ The rate of decarboxylation of a β,γ -unsaturated acid was increased $\sim 10^5$ – 10^6 times by introduction of a β -methoxy group, indicating that the cyclic transition state has dipolar character.⁶⁵⁰

β -Keto acids⁶⁵¹ are easily decarboxylated, but such acids are usually prepared from β -keto esters, and the esters are easily decarboxylated themselves on hydrolysis without isolation of the acids.⁶⁵² This decarboxylation of β -keto esters

involving cleavage on the carboxyl side of the substituted methylene group (arrow) is carried out under acidic, neutral, or slightly basic conditions to yield a ketone. When strongly basic conditions are used, cleavage occurs on the other side of the CR_2 group (**12-43**). β -Keto esters can be decarbalkoxylated without passing through the free-acid stage by treatment with boric anhydride (B_2O_3) at 150°C .⁶⁵³ The alkyl portion of the ester (R') is converted to an alkene or, if it lacks a β hydrogen, to an ether $\text{R}'\text{OR}'$. Another method for the decarbalkoxylation of β -keto esters, malonic esters, and α -cyano esters consists of heating the substrate in wet DMSO containing NaCl , Na_3PO_4 , or some other simple salt.⁶⁵⁴ In this method too, the free acid is probably not an intermediate, but here the alkyl portion of the substrate is converted to the corresponding alcohol. Ordinary carboxylic acids, containing no activating groups, can be decarboxylated by conversion to esters of *N*-hydroxypyridine-2-thione and treatment of these with Bu_3SnH .⁶⁵⁵ A free-radical mechanism is likely. α -Amino acids have been decarboxylated by treatment with a catalytic amount of 2-cyclohexenone.⁶⁵⁶ Amino acids are decarboxylated by sequential treatment with NBS at pH 5 followed by NaBH_4 and NiCl_2 .⁶⁵⁷ Certain decarboxylations can also be accomplished photochemically.⁶⁵⁸ See also, the decarbonylation of acyl halides, mentioned in **14-32**. In some cases, decarboxylations can give organometallic compounds: $\text{RCOOM} \rightarrow \text{RM} + \text{CO}_2$.⁶⁵⁹

Some of the decarboxylations listed in *Organic Syntheses* are performed with concomitant ester or nitrile hydrolysis and others are simple decarboxylations.

12-41 Cleavage of Alkoxides

Hydro-de-(α -oxidoalkyl)-substitution

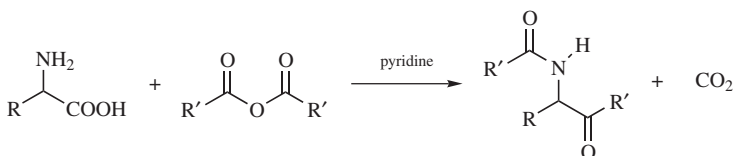

Alkoxides of tertiary alcohols can be cleaved in a reaction that is essentially the reverse of addition of carbanions to ketones (16-24).⁶⁶⁰ The reaction is unsuccessful when the R groups are simple unbranched alkyl groups, for example, the alkoxide of triethylcarbinol. Cleavage is accomplished with branched alkoxides, such as the alkoxides of diisopropylneopentylcarbinol or tri-*tert*-butylcarbinol.⁶⁶¹ Allylic,⁶⁶² benzylic,⁶⁶³ and aryl groups also cleave; for example, the alkoxide of triphenylcarbinol gives benzene and benzophenone. Studies in the gas phase show that the cleavage is a simple one, giving the carbanion and ketone directly in one step.⁶⁶⁴ However, with some substrates in solution, substantial amounts of dimer R-R have been found, indicating a radical pathway.⁶⁶⁵ Hindered alcohols (not the alkoxides) also lose one R group by cleavage, also by a radical pathway.⁶⁶⁶

The reaction has been used for extensive mechanistic studies (see p. 758).

When an α -amino acid is treated with an anhydride in the presence of pyridine, the carboxyl group is replaced by an acyl group and the NH_2 becomes acylated. This is called the *Dakin–West reaction*.⁶⁶⁷ The mechanism involves formation of an oxazolone.⁶⁶⁸ The reaction sometimes takes place on carboxylic acids even when an amino group is not present. A number of *N*-substituted amino acids, $\text{RCH}(\text{NHR}')\text{COOH}$, give the corresponding *N*-alkylated products.

OS IV, 5; V, 27.

B. Acyl Cleavages

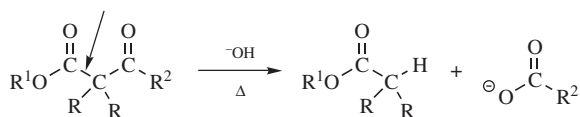

In these reactions (**12-43–12-46**), a carbonyl group is attacked by a hydroxide ion (or amide ion), giving an intermediate that undergoes cleavage to a carboxylic acid (or an amide). With respect to the leaving group, this is nucleophilic substitution at a carbonyl group and the mechanism is the tetrahedral one discussed in Chapter 10.

With respect to R this is of course electrophilic substitution. The mechanism is usually $\text{S}_{\text{E}}1$.

12-43 Basic Cleavage of β -Keto Esters and β -Diketones

Hydro-de-acylation

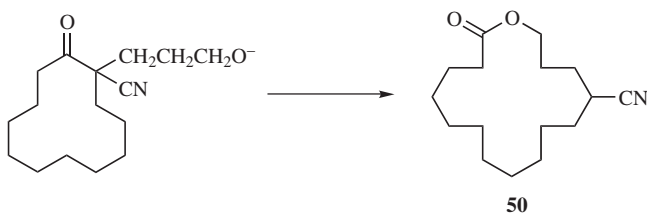

When β -keto esters are treated with concentrated base, cleavage occurs, but is on the keto side of the CR_2 group (arrow) in contrast to the acid cleavage mentioned on page 838. The products are a carboxylic ester and the salt of an acid. However, the utility of the reaction is somewhat limited by the fact that decarboxylation is a side reaction, even under basic conditions. β -Diketones behave similarly to give a ketone and the salt of a carboxylic acid. With both β -keto esters and β -diketones, ^-OEt can be used instead of ^-OH , in which case the ethyl esters of the corresponding acids are obtained instead of the salts. In the case of β -keto esters, this is the reverse of Claisen condensation (**16-85**). The similar cleavage of cyclic α -cyano

⁶⁶⁷For a review, see Buchanan, G.L. *Chem. Soc. Rev.* **1988**, 17, 91.

ketones, in an intramolecular fashion, has been used to effect a synthesis of macrocyclic lactones such as **50**.⁶⁶⁹

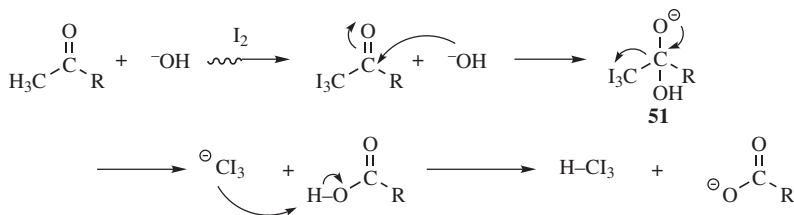

Activated F^- (from KF and a crown ether) has been used as the base to cleave an α -cyano ketone.⁶⁷⁰

OS **II**, 266, 531; **III**, 379; **IV**, 415, 957; **V**, 179, 187, 277, 533, 747, 767.

12-44 Haloform Reaction

In the *haloform reaction*, methyl ketones (and the only methyl aldehyde, acetaldehyde) are cleaved with halogen and a base.⁶⁷¹ The halogen can be bromine, chlorine, or iodine. What takes place is actually a combination of two reactions. The first is an example of **12-4**, in which, under the basic conditions employed, the methyl group is trihalogenated. Then the resulting trihalo ketone is attacked by hydroxide ion to give tetrahedral intermediate **51**.⁶⁷² The X_3C^- group is a sufficiently good leaving group (not HX_2C^- or H_2XC^-) that a carboxylic acid is formed, which quickly reacts with the carbanion to give the final products. Primary or secondary methylcarbinols also give the reaction, because they are oxidized to the carbonyl compounds under the conditions employed.

⁶⁷¹For a review of this and related reactions, see Chakrabarty, S.K., in Trahanovsky, W.S. *Oxidation in Organic Chemistry*, pt. C, Academic Press, NY, **1978**, pp. 343–370.

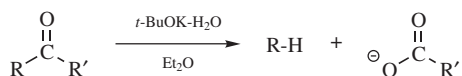

⁶⁷²For a complete kinetic analysis of the chlorination of acetone, see Guthrie, J.P.; Cossar, J. *Can. J. Chem.* **1986**, *64*, 1250. For a discussion of the mechanism of the cleavage step, see Zucco, C.; Lima, C.F.; Rezende, M.C.; Vianna, J.F.; Nome, F. *J. Org. Chem.* **1987**, *52*, 5356.

As with **12-4**, the rate-determining step is the preliminary enolization of the methyl ketone.⁶⁷³ A side reaction is α halogenation of the non-methyl R group. Sometimes these groups are also cleaved.⁶⁷⁴ The reaction cannot be applied to F_2 , but ketones of the form $RCOCF_3$ (R = alkyl or aryl) give fluoroform and $RCOO^-$ when treated with base.⁶⁷⁵ Rate constants for cleavage of X_3CCOPh (X = F, Cl, Br) were found to be in the ratio $1 : 5.3 \times 10^{10} : 2.2 \times 10^{13}$, showing that an F_3C^- group cleaves much more slowly than the others.⁶⁷⁶ The haloform reaction is often used as a test for methylcarbinols and methyl ketones. Iodine is most often used as the test reagent, since iodoform (CHI_3) is an easily identifiable yellow solid. The reaction is also frequently used for synthetic purposes. Methyl ketones $RCOCH_3$ can be converted directly to methyl esters $RCOOCH_3$ by an electrochemical reaction.⁶⁷⁷ Trifluoromethyl ketones have been converted to ethyl esters via treatment with NaH in aqueous DMF followed by reaction with bromoethane.⁶⁷⁸

OS I, 526; II, 428; III, 302; IV, 345; V, 8. Also see, OS VI, 618.

12-45 Cleavage of Nonenolizable Ketones

Hydro-de-acylation

Ordinary ketones are generally much more difficult to cleave than trihalo ketones or β -diketones, because the carbanion intermediates in these cases are more stable than simple carbanions. However, nonenolizable ketones can be cleaved by treatment with a 10:3 mixture of $t\text{-BuOK-H}_2\text{O}$ in an aprotic solvent, such as ether, DMSO, 1,2-dimethoxyethane (glyme),⁶⁷⁹ or with solid $t\text{-BuOK}$ in the absence of a solvent.⁶⁸⁰ When the reaction is applied to monosubstituted diaryl ketones, that aryl group preferentially cleaves that comes off as the more stable carbanion, except that aryl groups substituted in the ortho position are more readily cleaved than otherwise because of the steric effect (relief of strain).^{680,681} In certain cases, cyclic ketones can be cleaved by base treatment, even if they are enolizable.⁶⁸²

12-46 The Haller–Bauer Reaction

Hydro-de-acylation

Cleavage of ketones with sodium amide is called the *Haller–Bauer reaction*.⁶⁸³ As with **12-45**, which is exactly analogous, the reaction is usually applied only to non-enolizable ketones, most often to ketones of the form ArCOCR_3 , where the products R_3CCONH_2 are not easily attainable by other methods. However, many other ketones have been used, although benzophenone is virtually unaffected. It has been shown that the configuration of optically active alkyl groups (R) is retained.⁶⁸⁴ The NH_2 loses its proton from the tetrahedral intermediate **52** before the R group is cleaved.⁶⁸⁵

An extension of this cleavage process involves the reaction of α -nitro ketones ($\text{O}=\text{C}-\text{CHRNO}_2$) with a primary amine, neat, to give the corresponding amide ($\text{O}=\text{C}-\text{NHR}'$).⁶⁸⁶

OS V, 384, 1074.

C. Other Cleavages

12-47 The Cleavage of Alkanes

Hydro-de-*tert*-butylation, and so on

The C–C bonds of alkanes can be cleaved by treatment with superacids⁴⁸ (p. 236). For example, neopentane in $\text{FSO}_3\text{H}-\text{SbF}_5$ can cleave to give methane and the *tert*-butyl cation. The C–H cleavage (see **12-1**) is a competing reaction and, for example, neopentane can give H_2 and the *tert*-pentyl cation (formed by rearrangement of the initially formed neopentyl cation) by this pathway. In general, the order of reactivity is tertiary C–H > C–C > secondary C–H \gg primary C–H,

⁶⁸³For a review, see Gilday, J.P.; Paquette, L.A. *Org. Prep. Proced. Int.* **1990**, 22, 167. For an improved procedure, see Kaiser, E.M.; Warner, C.D. *Synthesis* **1975**, 395.

although steric factors cause a shift in favor of C–C cleavage in such a hindered compound as tri-*tert*-butylmethane. The mechanism is similar to that shown in **12-1** and **12-20** and involves attack by H^+ on the C–C bond to give a pentavalent cation.

Catalytic hydrogenation seldom breaks unactivated C–C bonds (i.e., $R-R' + H_2 \rightarrow RH + R'H$), but methyl and ethyl groups have been cleaved from substituted adamantanes by hydrogenation with a Ni– Al_2O_3 catalyst at about 250°C.⁶⁸⁷ Certain C–C bonds have been cleaved by alkali metals.⁶⁸⁸

The C–C bond of 2-allyl-2-arylmalonate derivatives was cleaved, with loss of the allylic group to give the 2-arylmalonate, by treatment with a nickel catalyst.⁶⁸⁹

12-48 Decyanation or Hydro-de-cyanation

The cyano group of alkyl nitriles can be removed⁶⁹⁰ by treatment with metallic sodium, either in liquid ammonia,⁶⁹¹ or together with tris(acetylacetonato)iron(III) [$Fe(acac)_3$]⁶⁹² or, with lower yields, titanocene. The two procedures are complementary. Although both can be used to decyanate many kinds of nitriles, the Na– NH_3 method gives high yields with R groups, such as trityl, benzyl, phenyl, and tertiary alkyl, but lower yields (~35–50%) when R = primary or secondary alkyl. On the other hand, primary and secondary alkyl nitriles are decyanated in high yields by the Na– $Fe(acac)_3$ procedure. Sodium in liquid ammonia is known to be a source of solvated electrons, and the reaction may proceed through the free radical $R\cdot$ that would then be reduced to the carbanion R^- , which by abstraction of a proton from the solvent, would give RH. The mechanism with $Fe(acac)_3$ is presumably different. Another procedure,⁶⁹³ which is successful for R = primary, secondary, or tertiary, involves the use of potassium metal and the crown ether dicyclohexano-18-crown-6 in toluene.⁶⁹⁴

α -Amino and α -amido nitriles $\text{RCH}(\text{CN})\text{NR}'_2$ and $\text{RCH}(\text{CN})\text{NHCOR}'$ can be decyanated in high yield by treatment with NaBH_4 .⁶⁹⁵

ELECTROPHILIC SUBSTITUTION AT NITROGEN

In most of the reactions in this section, an electrophile bonds with the unshared pair of a nitrogen atom. The electrophile may be a free positive ion or a positive species attached to a carrier that breaks off in the course of the attack or shortly after:

Further reaction of **53** depends on the nature of Y and of the other groups attached to the nitrogen.

12-49 The Conversion of Hydrazines to Azides

Hydrazine–azide transformation

Monosubstituted hydrazines treated with nitrous acid give azides in a reaction exactly analogous to the formation of aliphatic diazo compounds mentioned in **13-19**. Among other reagents used for this conversion have been N_2O_4 ⁶⁹⁶ and nitrosyl tetrafluoroborate (NOBF_4).⁶⁹⁷

OS **III**, 710; **IV**, 819; **V**, 157.

12-50 N-Nitrosation

N-Nitroso-de-hydrogenation

When secondary amines are treated with nitrous acid (typically formed from sodium nitrite and a mineral acid),⁶⁹⁸ N-nitroso compounds (also called

nitrosamines) are formed.⁶⁹⁹ The reaction can be accomplished with dialkyl-, diaryl-, or alkylarylamines, and even with mono-*N*-substituted amides: $\text{RCONHR}' + \text{HONO} \rightarrow \text{RCON}(\text{NO})\text{R}'$.⁷⁰⁰ Tertiary amines have also been *N*-nitrosated, but in these cases one group cleaves, so that the product is the nitroso derivative of a secondary amine.⁷⁰¹ The group that cleaves appears as an aldehyde or ketone. Other reagents have also been used, for example, NOCl , which is useful for amines or amides that are not soluble in an acidic aqueous solution or where the *N*-nitroso compounds are highly reactive. *N*-Nitroso compounds can be prepared in basic solution by treatment of secondary amines with gaseous N_2O_3 , N_2O_4 ,⁷⁰² or alkyl nitrites,⁷⁰³ and, in aqueous or organic solvents, by treatment with BrCH_2NO_2 .⁷⁰⁴ Secondary amines are converted to the *N*-nitroso compound with H_5IO_6 on wet silica.⁷⁰⁵

The mechanism of nitrosation is essentially the same as in **13-19** up to the point where **54** is formed. Since this species cannot lose a proton, it is stable and the reaction ends there. The attacking entity can be any of those mentioned in **13-19**. The following has been suggested as the mechanism for the reaction with tertiary amines:⁷⁰⁶

The evidence for this mechanism includes the facts that nitrous oxide is a product (formed by $2 \text{HNO} \rightarrow \text{H}_2\text{O} + \text{N}_2\text{O}$) and that quinuclidine, where the nitrogen is at a bridgehead, and therefore cannot give elimination, does not react. Tertiary amines have also been converted to nitrosamines with nitric acid in Ac_2O ⁷⁰⁷ and with N_2O_4 .⁷⁰⁸

Amines and amides can be *N*-nitrated⁷⁰⁹ with nitric acid,⁷¹⁰ or NO_2^+ ,⁷¹¹ and aromatic amines can be converted to triazenes with diazonium salts. Aliphatic primary amines can also be converted to triazenes if the diazonium salts contain electron-withdrawing groups.⁷¹² C-Nitrosation is discussed at **11-3** and **12-8**.

(ArNONAr, ArNONAr', and Ar'NONAr') are obtained⁷¹⁴ and the unsymmetrical product (ArNONAr') is likely to be formed in the smallest amount. This behavior is probably caused by an equilibration between the starting compounds prior to the actual reaction (ArNO + Ar'NHOH → Ar'NO + ArNHOH).⁷¹⁵ The mechanism⁷¹⁶ has been investigated in the presence of base. Under these conditions both reactants are converted to radical anions, which couple:

These radical anions have been detected by esr.⁷¹⁷ This mechanism is consistent with the following result: when nitrosobenzene and phenylhydroxylamine are coupled, ¹⁸O and ¹⁵N labeling show that the two nitrogens and the two oxygens become equivalent.⁷¹⁸ Unsymmetrical azoxy compounds can be prepared⁷¹⁹ by combination of a nitroso compound with an *N,N*-dibromoamine. Symmetrical and unsymmetrical azo and azoxy compounds are produced when aromatic nitro compounds react with aryliminodimagnesium reagents ArN(MgBr)₂.⁷²⁰

12-52 *N*-Halogenation

N-Halo-de-hydrogenation

Treatment with sodium hypochlorite or hypobromite converts primary amines into *N*-halo- or *N,N*-dihaloamines. Secondary amines can be converted to *N*-halo secondary amines. Similar reactions can be carried out on unsubstituted and *N*-substituted amides and on sulfonamides. With unsubstituted amides the *N*-halogen product is seldom isolated but usually rearranges (see **18-13**); however, *N*-halo-*N*-alkyl amides and *N*-halo imides are quite stable. The important reagents NBS and NCS are made in this manner. *N*-Halogenation has also been accomplished with other

sulfur.⁷³⁶ R can be alkyl or aryl. The same thing can be done with secondary amines, by using $\text{Pd}(\text{OAc})_2\text{-I}_2\text{-K}_2\text{CO}_3$.⁷³⁷ Primary aromatic amines react with β -keto esters and a Mo-ZrO_2 catalyst to give the symmetrical urea.⁷³⁸ Treatment of a secondary amine with nitrobenzene, selenium, and carbon monoxide leads to the unsymmetrical urea.⁷³⁹ (3) When PdCl_2 is the catalyst, primary amines yield isocyanates.⁷⁴⁰ Isocyanates can also be obtained by treatment of CO with azides: $\text{RN}_3 + \text{CO} \rightarrow \text{RNCO}$,⁷⁴¹ or with an aromatic nitroso or nitro compound and a rhodium complex catalyst.⁷⁴² Primary amines react with di-*tert*-butyltricarboxylate to give the isocyanate.⁷⁴³ Lactams are converted to the corresponding *N*-chloro lactam with $\text{Ca}(\text{OCl})_2$ with moist alumina in dichloromethane.⁷⁴⁴

A fourth type of product, a carbamate $\text{RNHCOOR}'$, can be obtained from primary or secondary amines, if these are treated with CO, O_2 , and an alcohol $\text{R}'\text{OH}$ in the presence of a catalyst.⁷⁴⁵ Primary amines react with dimethyl carbonate in supercritical CO_2 (see p. 414) to give a carbamate.⁷⁴⁶ Carbamates can also be obtained from nitroso compounds, by treatment with CO, $\text{R}'\text{OH}$, $\text{Pd}(\text{OAc})_2$, and $\text{Cu}(\text{OAc})_2$,⁷⁴⁷ and from nitro compounds.⁷⁴⁸ When allylic amines ($\text{R}_2\text{C}=\text{CHRCHRNR}'_2$) are treated with CO and a palladium-phosphine catalyst, the CO inserts to produce the β,γ -unsaturated amides ($\text{R}_2\text{C}=\text{CHRCHRCONR}'_2$) in good yields.⁷⁴⁹ Ring-expanded lactams are obtained from cyclic amines via a similar reaction⁷⁵⁰ (see also, **16-22**). Silyloxy carbamates ($\text{RNHCO}_2\text{SiR}'_3$) can be prepared by the reaction of a primary amine with carbon dioxide and triethylamine, followed by reaction with triisopropylsilyl triflate and tetrabutylammonium fluoride.⁷⁵¹

Carbon dioxide reacts with amines (ArNH_2) and alkyl halides, under electrolysis conditions, to give the corresponding carbamate (ArNHCO_2Et).⁷⁵² Secondary

Aromatic Substitution, Nucleophilic and Organometallic

On p. 481, it was pointed out that nucleophilic substitutions proceed so slowly at an aromatic carbon that the reactions of Chapter 10 are not feasible for aromatic substrates. There are, however, exceptions to this statement, and it is these exceptions that form the subject of this chapter.¹ Reactions that *are* successful at an aromatic substrate are largely of four kinds: (1) reactions activated by electron-withdrawing groups ortho and para to the leaving group; (2) reactions catalyzed by very strong bases and proceeding through arylne intermediates; (3) reactions initiated by electron donors; and (4) reactions in which the nitrogen of a diazonium salt is replaced by a nucleophile. It is noted that solvent effects can be important.² Also, not all the reactions discussed in this chapter fit into these categories, and certain transition-metal catalyzed coupling reactions are included because they involve replacement of a leaving group on an aromatic ring.

MECHANISMS

There are four principal mechanisms for aromatic nucleophilic substitution.³ Each of the four is similar to one of the aliphatic nucleophilic substitution mechanisms discussed in Chapter 10.

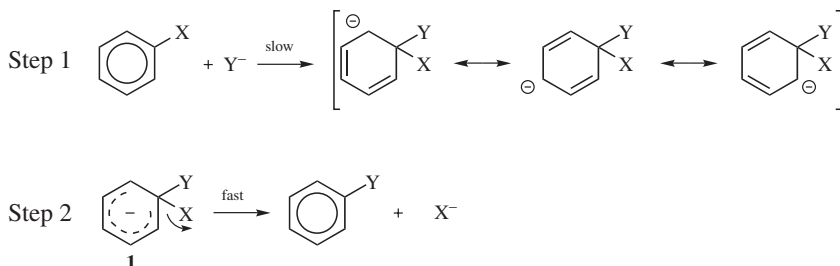

¹For a review of aromatic nucleophilic substitution, see Zoltewicz, J.A. *Top. Curr. Chem.* **1975**, *59*, 33.

Chem.* **1975**, *59*, 33.

The S_NAr Mechanism⁴

By far the most important mechanism for nucleophilic aromatic substitution consists of two steps, attack of the nucleophilic species at the ipso carbon of the aromatic ring (the carbon bearing the leaving group in this case), followed by elimination of the leaving group and regeneration of the aromatic ring.

The first step is usually, but not always, rate determining. It can be seen that this mechanism greatly resembles the tetrahedral mechanism discussed in Chapter 16 and, in another way, the arenium ion mechanism of electrophilic aromatic substitution discussed in Chapter 11. In all three cases, the attacking species forms a bond with the substrate, giving an intermediate, such as **1**, and then the leaving group departs. We refer to this mechanism as the S_NAr mechanism.⁵ The IUPAC designation is A_N + D_N (the same as for the tetrahedral mechanism; compare the designation A_E + D_E for the arenium ion mechanism). This mechanism is generally found where activating groups are present on the ring (see p. 864).

There is a great deal of evidence for the mechanism; we shall discuss only some of it.³ Probably the most convincing evidence was the isolation, as long ago as 1902, of the intermediate **2** in the reaction between 2,4,6-trinitrophenetole and methoxide ion.⁶ Intermediates of this type are stable salts, called *Meisenheimer* or *Meisenheimer–Jackson salts*,⁷ and many more have been isolated.⁸ The structures

⁴High pressure S_NAr reactions are known. see Barrett, I.C.; Kerr, M.A. *Tetrahedron Lett.* **1999**, *40*, 2439.

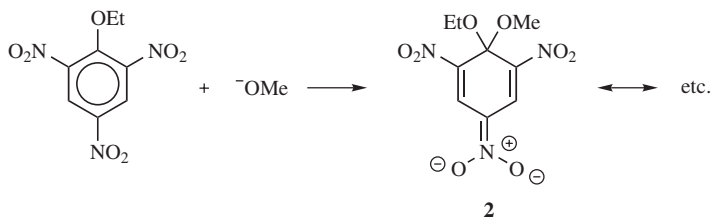

⁵The mechanism has also been called by other names, including the S_N2Ar, the addition–elimination, and the intermediate complex mechanism. See Wu, Z.; Glaser, R. *J. Am. Chem. Soc.* **2004**, *126*, 10632. See also, Terrier, F.; Mokhtari, M.; Goumont, T.; Hallé, J.-C.; Buncel, E. *Org. Biomol. Chem.* **2003**, *1*, 1757.

⁶Meisenheimer, J. *Liebigs Ann. Chem.* **1902**, *323*, 205. Similar salts were isolated even earlier by Jackson, C.L.; see Jackson, C.L.; Gazzolo, F.H. *Am. Chem. J.* **1900**, *23*, 376; Jackson, C.L.; Earle, R.B. *Am. Chem. J.*, **1903**, *29*, 89.

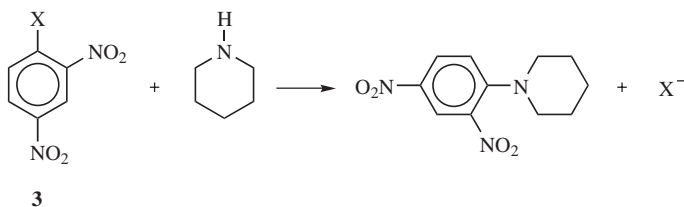

⁷Nucleophilic aromatic substitution for heteroatom nucleophiles through electrochemical oxidation of intermediate σ-complexes (Meisenheimer complexes) in simple nitroaromatic compounds has been reported, see Gallardo, I.; Guirado, G.; Marquet, J. *J. Org. Chem.* **2002**, *67*, 2548.

⁸For a monograph on Meisenheimer salts and on this mechanism, see Buncel, E.; Crampton, M.R.; Strauss, M.J.; Terrier, F. *Electron Deficient Aromatic- and Heteroaromatic-Base Interactions*, Elsevier, NY, **1984**. For reviews of structural and other studies, see Illuminati, G.; Stegel, F. *Adv. Heterocycl. Chem.* **1983**, *34*, 305; Artamkina, G. A.; Egorov, M.P.; Beletskaya, I.P. *Chem. of several of these intermediates

have been proved by NMR⁹ and by X-ray crystallography.¹⁰ Further evidence comes from studies of the effect of the leaving group on the reaction. If the mechanism were similar to either the S_N1 or S_N2 mechanisms described in Chapter 10, the Ar–X bond would be broken in the rate-determining step. In the S_NAr mechanism, this bond is not broken until after the rate-determining step (i.e. if step 1 is rate determining). There is some evidence that electron transfer may be operative during this process.¹¹ We would predict from this that if the S_NAr mechanism is operating, a change in leaving group should not have much effect on the reaction rate. In the reaction of dinitro compound **3** with piperidine,

when X was Cl, Br, I, SPh, SO₂Ph, or *p*-nitrophenoxy, the rates differed only by a factor of ~5.¹² This behavior would not be expected in a reaction in which the Ar–X bond is broken in the rate-determining step. We do not expect the rates to be *identical*, because the nature of X affects the rate at which Y attacks. An increase in the electronegativity of X causes a decrease in the electron density at the site of attack, resulting in a faster attack by a nucleophile. Thus, in the reaction just mentioned, when X = F, the relative rate was 3300 (compared with I = 1). The very fact that fluoro is the best leaving group among the halogens in most aromatic nucleophilic substitutions is good evidence that the mechanism is different from the S_N1

⁹First done by Crampton, M.R.; Gold, V. *J. Chem. Soc. B* **1966**, 893. A good review of spectral studies is found, in Buncl, E.; Crampton, M.R.; Strauss, M.J.; Terrier, F. *Electron Deficient Aromatic- and Heteroaromatic-Base Interactions*, Elsevier, NY, **1984**, pp. 15–133.

and the S_N2 mechanisms, where fluoro is by far the poorest leaving group of the halogens. This is an example of the element effect (p. 475).

The pattern of base catalysis of reactions with amine nucleophiles provides additional evidence. These reactions are catalyzed by bases only when a relatively poor leaving group (e.g., OR) is present (not Cl or Br) and only when relatively bulky amines are nucleophiles.¹³ Bases could not catalyze step 1, but if amines are nucleophiles, bases can catalyze step 2. Base catalysis is found precisely in those cases where the amine moiety cleaves easily but X does not, so that k_{-1} is large and step 2 is rate determining. This is evidence for the S_NAr mechanism because it implies two steps. Furthermore, in cases where bases *are* catalysts, they catalyze only at

low base concentrations: a plot of the rate against the base concentration shows that small increments of base rapidly increase the rate until a certain concentration of base is reached, after which further base addition no longer greatly affects the rate. This behavior, based on a partitioning effect (see p. 660), is also evidence for the S_NAr mechanism. At low base concentration, each increment of base, by increasing the rate of step 2, increases the fraction of intermediate that goes to product rather than reverting to reactants. At high base concentration the process is virtually complete: there is very little reversion to reactants and the rate becomes dependent on step 1. Just how bases catalyze step 2 has been investigated. For protic solvents two proposals have been presented. One is that step 2 consists of two steps: rate-determining deprotonation of **4** followed by rapid loss of X,

and that bases catalyze the reaction by increasing the rate of the deprotonation step.¹⁴ According to the other proposal, loss of X assisted by BH^+ is rate determining.¹⁵ Two mechanisms, both based on kinetic evidence, have been proposed for aprotic solvents, such as benzene. In both proposals the ordinary S_NAr mechanism

operates, but in one the attacking species involves two molecules of the amine (the *dimer mechanism*),¹⁶ while in the other there is a cyclic transition state.¹⁷ Further evidence for the S_NAr mechanism has been obtained from $^{18}O/^{16}O$ and $^{15}N/^{14}N$ isotope effects.¹⁸

Step 1 of the S_NAr mechanism has been studied for the reaction between picryl chloride (as well as other substrates) and ^-OH ions (**13-1**), and spectral evidence has been reported¹⁹ for two intermediates, one a π complex (p. 662), and the other a radical ion–radical pair:

As with the tetrahedral mechanism at an acyl carbon, nucleophilic catalysis (p. 1259) has been demonstrated with an aryl substrate, in certain cases.²⁰ There is also evidence of an interaction of anions with the π -cloud of aromatic compounds.²¹

The S_N1 Mechanism

For aryl halides and sulfonates, even active ones, a unimolecular S_N1 mechanism (IUPAC: $D_N + A_N$) is very rare; it has only been observed for aryl triflates in which both ortho positions contain bulky groups (*tert*-butyl or SiR_3).²² It is in reactions with diazonium salts²³ that this mechanism is important:²⁴

²⁴Aryl iodonium salts Ar_2I^+ also undergo substitutions by this mechanism (and by a free-radical mechanism).

Among the evidence for the S_N1 mechanism²⁵ with aryl cations as intermediates,^{26,27} is the following:²⁸

1. The reaction rate is first order in diazonium salt and independent of the concentration of Y.
2. When high concentrations of halide salts are added, the product is an aryl halide but the rate is independent of the concentration of the added salts.
3. The effects of ring substituents on the rate are consistent with a unimolecular rate-determining cleavage.²⁹
4. When reactions were run with substrate deuterated in the ortho position, isotope effects of ~ 1.22 were obtained.³⁰ It is difficult to account for such high secondary isotope effects in any other way except that an incipient phenyl cation is stabilized by hyperconjugation,³¹ which is reduced when hydrogen is replaced by deuterium.

5. That the first step is reversible cleavage³² was demonstrated by the observation that when $\text{Ar}^{15}\text{H}\text{N}\equiv\text{N}$ was the reaction species, recovered starting

material contained not only $\text{Ar}^{15}\overset{\text{H}}{\text{N}}\equiv\text{N}$, but also $\text{Ar}\overset{\text{H}}{\text{N}}\equiv\overset{15}{\text{N}}$.^{33,34} This could arise only if the nitrogen breaks away from the ring and then returns. Additional evidence was obtained by treating $\text{Ph}\overset{\text{H}}{\text{N}}\equiv\overset{15}{\text{N}}$ with unlabeled N_2 at various pressures. At 300 atm, the recovered product had lost $\sim 3\%$ of the labeled nitrogen, indicating that PhN_2^+ was exchanging with atmospheric N_2 .³⁴

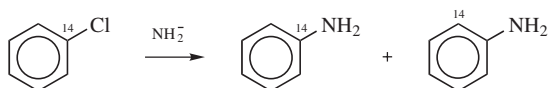

There is kinetic and other evidence³⁵ that step 1 is more complicated and involves two steps, both reversible:

Intermediate **5**, which is probably some kind of a tight ion–molecule pair, has been trapped with carbon monoxide.³⁶

The Benzyne Mechanism³⁷

Some aromatic nucleophilic substitutions are clearly different in character from those that occur by the $\text{S}_{\text{N}}\text{Ar}$ mechanism (or the $\text{S}_{\text{N}}1$ mechanism). These substitutions occur on aryl halides that have no activating groups; bases are required that are stronger than those normally used; and most interesting of all, the incoming group does not always take the position vacated by the leaving group. That the latter statement is true was elegantly demonstrated by the reaction of 1-¹⁴C-chlorobenzene with potassium amide:

The product consisted of almost equal amounts of aniline labeled in the 1 position and in the 2 position.³⁸

A mechanism that can explain all these facts involves elimination followed by addition. In step 1, a suitable base removes the ortho hydrogen, with subsequent (or concomitant) loss of the chlorine (leaving group) to

generate symmetrical intermediate **6**³⁹ is called benzyne (see below).⁴⁰ In step 2, benzyne is attacked by the NH_3 at either of two positions, which explains why about half of the aniline produced from the radioactive chlorobenzene was labeled at the 2 position. The fact that the 1 and 2 positions were not labeled equally is the result of a small isotope effect. Other evidence for this mechanism is the following:

1. If the aryl halide contains two ortho substituents, the reaction should not be able to occur. This is indeed the case.³⁶
2. It had been known many years earlier that aromatic nucleophilic substitution occasionally results in substitution at a different position. This is called *cine substitution*⁴¹ and can be illustrated by the conversion of *o*-bromoanisole to *m*-aminoanisole.⁴² In this particular case, only the meta isomer is

formed. The reason a 1:1 mixture is not formed is that the intermediate **7** is not symmetrical and the methoxy group directs the incoming group meta, but not ortho (see p. 867). However, not all cine substitutions proceed by this kind of mechanism (see **13-30**).

3. The fact that the order of halide reactivity is $\text{Br} > \text{I} > \text{Cl} > \text{F}$ (when the reaction is performed with KNH_2 in liquid NH_3) shows that the $\text{S}_{\text{N}}\text{Ar}$ mechanism is not operating here.³⁸

⁴⁰For other methods to generate benzyne, see Kitamura, T.; Meng, Z.; Fujiwara, Y. *Tetrahedron Lett.* **2000**, 41, 6611, and references cited therein; Kawabata, H.; Nishino, T.; Nishiyama, Y.; Sonoda, N. *Tetrahedron Lett.* **2002**, 43, 4911, and references cited therein.

⁴¹For a review, see Suwiński, J.; Wierczek, K. *Tetrahedron* **2001**, 57, 1639.

⁴²This example is from Gilman, H.; Avakian, S. *J. Am. Chem. Soc.* **1945**, 67, 349. For a table of many such examples, see Bunnett, J.F.; Zahler, R.E. *Chem. Rev.* **1951**, 49, 273, p. 385.

In the conversion of the substrate to **7**, either proton removal or subsequent loss of halide ion can be rate determining. In fact, the unusual leaving-group order just mentioned ($\text{Br} > \text{I} > \text{Cl}$) stems from a change in the rate-determining step. When the leaving group is Br or I, proton removal is rate-determining and the rate order for this step is $\text{F} > \text{Cl} > \text{Br} > \text{I}$. When Cl or F is the leaving group, cleavage of the C–X bond is rate determining and the order for this step is $\text{I} > \text{Br} > \text{Cl} > \text{F}$. Confirmation of the latter order was found in a direct competitive study. *meta*-Dihalo-benzenes in which the two halogens are different were treated with NH_2^- .⁴³ In such compounds, the most acidic hydrogen is the one between the two halogens; when it leaves, the remaining anion can lose either halogen. Therefore, a study of which halogen is preferentially lost provides a direct measure of leaving-group ability. The order was found to be $\text{I} > \text{Br} > \text{Cl}$.^{43,44}

Species, such as **6** and **7**, are called *benzynes* (sometimes *dehydrobenzenes*), or more generally, *arynes*,⁴⁵ and the mechanism is known as the *benzyne mechanism*. Benzynes are very reactive. Neither benzyne nor any other aryne has yet been isolated under ordinary conditions,⁴⁶ but benzyne has been isolated in an argon matrix at 8 K,⁴⁷ where its IR spectrum could be observed. In addition, benzynes can be trapped; for example, they undergo the Diels–Alder reaction (see **15-60**). Note that the extra pair of electrons does not affect the

aromaticity. However, evaluation by a series of aromaticity indicators, including magnetic susceptibility anisotropies and exaltations, nucleus-independent chemical shifts (NICS), and aromatic stabilization energies, and valence-bond Pauling resonance energies point to the *o*-benzyne $>$ *m*-benzyne $>$ *p*-benzyne aromaticity order.⁴⁸ The relative order with respect to benzene depends on the aromaticity criterion.⁴⁸ The aromatic sextet from the aromatic precursor functions as a closed ring, and the two additional electrons are merely located in a π orbital that covers only two carbons. Benzynes do not have a formal triple bond, since two canonical forms (**A** and **B**) contribute to the hybrid. The IR spectrum, mentioned above, indicates that **A** contributes more than **B**. Not only benzene rings, but other aromatic

rings⁴⁹ and even nonaromatic rings (p. 475) can react through this kind of intermediate. Of course, the non-aromatic rings do have a formal triple bond. When a benzyne unit is fused to a small ring, strain induced regioselectivity observed in its reactions.⁵⁰

The $S_{RN}1$ Mechanism

When 5-iodo-1,2,4-trimethylbenzene **7** was treated with KNH_2 in NH_3 , **8** and **10** were formed in the ratio 0.63:1. From what we have already seen, the presence of an unactivated substrate, a strong base, and the occurrence of cine substitution along with normal substitution would be strong indications of a benzyne mechanism. Yet if that were so, the 6-iodo isomer of **8** should have given **9** and **10** in the same ratio (because the same aryne intermediate would be formed in both cases), but in this case the ratio of **9**–**10** was 5.9:1 (the chloro and bromo analogs did give the same ratio, 1.46:1, showing that the benzyne mechanism may be taking place there).

To explain the iodo result, it has been proposed⁵¹ that besides the benzyne mechanism, this free-radical mechanism is also operating here:

This is called the $S_{RN}1$ mechanism,⁵² and many other examples are known (see **13-3**, **13-4**, **13-6**, **13-14**). The IUPAC designation is $T + D_N + A_N$.⁵³ Note that the

⁵³The symbol T is used for electron transfer.

last step of the mechanism produces $\text{ArI}^{\bullet-}$ radical ions, so the process is a chain mechanism (see p. 936).⁵⁴ An electron donor is required to initiate the reaction. In the case above it was solvated electrons from KNH_2 in NH_3 . Evidence was that the addition of potassium metal (a good producer of solvated electrons in ammonia) completely suppressed the cine substitution. Further evidence for the $\text{S}_{\text{RN}}1$ mechanism was that addition of radical scavengers (which would suppress a free-radical mechanism) led to **9:10** ratios much closer to 1.46:1. Numerous other observations of $\text{S}_{\text{RN}}1$ mechanisms that were stimulated by solvated electrons and inhibited by radical scavengers have also been recorded.⁵⁵ Further evidence for the $\text{S}_{\text{RN}}1$ mechanism in the case above was that some 1,2,4-trimethylbenzene was found among the products. This could easily be formed by abstraction by Ar^{\bullet} of H from the solvent NH_3 . Besides initiation by solvated electrons,⁵⁶ $\text{S}_{\text{RN}}1$ reactions have been initiated photochemically,⁵⁷ electrochemically,⁵⁸ and even thermally.⁵⁹

The $\text{S}_{\text{RN}}1$ reactions have a fairly wide scope. The efficiency of the reaction has been traced to the energy level of the radical anion of the substitution product.⁶⁰ There is no requirement for activating groups or strong bases, but in DMSO haloaromatics are less reactive as the stability of the anion increases.⁶¹ The reaction has also been done in liquid ammonia, promoted by ultrasound (p. 349),⁶² and ferrous ion has been used as a catalyst.⁶³ Alkyl, alkoxy, aryl, and COO^- groups do not interfere, although Me_2N , O^- , and NO_2 groups do interfere. Cine substitution is not found.

Other Mechanisms

There is no clear-cut proof that a one-step $\text{S}_{\text{N}}2$ mechanism, so important at a saturated carbon, ever actually occurs with an aromatic substrate. The hypothetical aromatic $\text{S}_{\text{N}}2$ process is sometimes called the *one-stage* mechanism to distinguish it from the *two-stage* $\text{S}_{\text{N}}\text{Ar}$ mechanism. A “clean” example of a $\text{S}_{\text{RN}}2$ reaction has been reported, the conversion of **11** to **12** in methanol.⁶⁴ Both the $\text{S}_{\text{RN}}1$ and $\text{S}_{\text{RN}}2$ reactions have been reviewed.⁶⁵

Some of the reactions in this chapter operate by still other mechanisms, among them an addition–elimination mechanism (see **13-17**). A new mechanism has been reported in aromatic chemistry, a reductively activated ‘polar’ nucleophilic aromatic substitution.⁶⁶ The reaction of phenoxide with *p*-dinitrobenzene in DMF shows radical features that cannot be attributed to a radical anion, and it is not $S_{RN}2$. The new designation was proposed to account for these results.

REACTIVITY

The Effect of Substrate Structure

In the discussion of electrophilic aromatic substitution (Chapter 11) equal attention was paid to the effect of substrate structure on reactivity (activation or deactivation) and on orientation. The question of orientation was important because in a typical substitution there are four or five hydrogens that could serve as leaving groups. This type of question is much less important for aromatic nucleophilic substitution, since in most cases there is only one potential leaving group in a molecule. Therefore attention is largely focused on the reactivity of one molecule compared with another and not on the comparison of the reactivity of different positions within the same molecule.

S_NAr Mechanism. These substitutions are accelerated by electron-withdrawing groups, especially in positions ortho and para to the leaving group⁶⁷ and hindered by electron-attracting groups. This is, of course, opposite to the effects of these groups on electrophilic substitutions, and the reasons are similar to those discussed in Chapter 11 (p. 660). Table 13.1 contains a list of groups arranged approximately in order of activating or deactivating ability.⁶⁸ Nitrogen atoms are also strongly activating (especially to the α and γ positions) and are even more so when quaternized.⁶⁹ Both 2- and 4-chloropyridine, for example, are often used as substrates. Heteroaromatic amine *N*-oxides are readily attacked by nucleophiles in the 2 and 4 positions, but the oxygen is generally lost in these reactions.⁷⁰

⁶⁶Marquet, J.; Casado, F.; Cervera, M.; Espín, M.; Gallardo, I.; Mir, M.; Niat, M. *Pure Appl. Chem.* **1995**, *67*, 703.

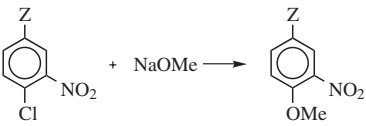

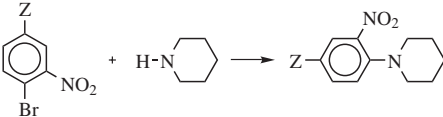

⁶⁷The effect of meta substituents has been studied much less, but it has been reported that here too, electron-withdrawing groups increase the rate: See Nurgatin, V.V.; Shamin, G.P.; Ginzburg, B.M. *J. Org. Chem, USSR* **1983**, *19*, 343.

^aFor reaction (a) the rates are relative to H; for (b) they are relative to NH₂.

^bThe comments on the left column are from Ref. 73.

The most highly activating group, N₂⁺, is seldom deliberately used to activate a reaction, but it sometimes happens that in the diazotization of a compound, such as *p*-nitroaniline or *p*-chloroaniline, the group para to the diazonium group is replaced by OH from the solvent or by X from ArN₂⁺ X⁻, to the surprise and chagrin of the investigator, who was trying only to replace the diazonium group and to leave the para group untouched. By far, the most common activating group is the nitro group and the most common substrates are 2,4-dinitrophenyl halides and 2,4,6-trinitrophenyl halides (also called picryl halides).⁷⁴ Polyfluorobenzenes⁷⁵ (e.g., C₆F₆), also undergo aromatic nucleophilic substitution quite well.⁷⁶ Benzene rings that lack activating substituents are generally not useful substrates for the S_NAr mechanism, because the two extra electrons in **1** are in an antibonding orbital (p. 34). Activating groups, by withdrawing electron density, are able to stabilize the intermediates and the

transition states leading to them. Reactions taking place by the S_NAr mechanism are also accelerated when the aromatic ring is coordinated with a transition metal.⁷⁷

Just as electrophilic aromatic substitutions were found more or less to follow the Hammett relationship (with σ^+ instead of σ ; see p. 402), so do nucleophilic substitutions, with σ^- instead of σ for electron-withdrawing groups.⁷⁸

Benzyne Mechanism. Two factors affect the position of the incoming group, the first being the direction in which the aryne forms.⁷⁹ When there are groups ortho or para to the leaving group, there is no choice:

but when a meta group is present, the aryne can form in two different ways:

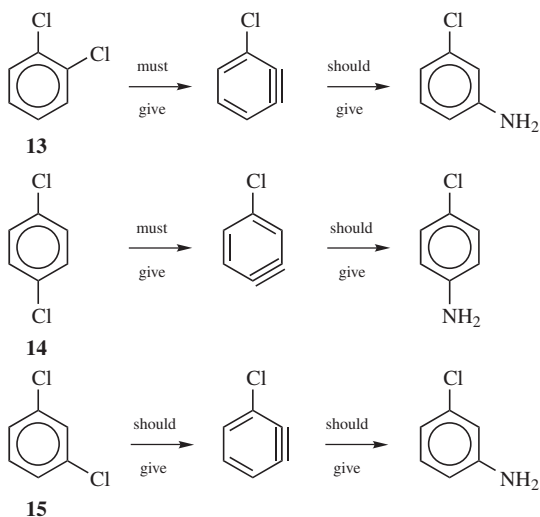

In such cases, the more acidic hydrogen is removed. Since acidity is related to the field effect of Z, it can be stated that an electron-attracting Z favors removal of the ortho hydrogen while an electron-donating Z favors removal of the para hydrogen. The second factor is that the aryne, once formed, can be attacked at two positions. The favored position for nucleophilic attack is the one that leads to the more stable carbanion intermediate, and this in turn also depends on the field effect of Z. For $-I$ groups, the more stable carbanion is the one in which the negative charge is closer to the substituent. These principles are illustrated by the reaction of the three dichlorobenzenes (**13-15**) with alkali-metal

⁷⁷For a review, see Balas, L.; Jhurry, D.; Latxague, L.; Grelier, S.; Morel, Y.; Hamdani, M.; Ardoin, N.; Astruc, D. *Bull. Soc. Chim. Fr.* **1990**, 401. ⁷⁸For a discussion of linear free-energy relationships in this reaction, see Bartoli, G.; Todesco, P.E. *Acc. Chem. Res.* **1977**, 10, 125. For a list of σ^- values, see Table 9.4 on p. 404.

⁷⁹This analysis is from Roberts, J.D.; Vaughan, C.W.; Carlsmith, L.A.; Semenov, D.A. *J. Am. Chem. Soc.* **1956**, 78, 611. For a discussion, see Hoffmann, R.W. *Dehydrobenzene and Cycloalkynes*, Academic Press, NY, **1973**, pp. 134–150.

amides to give the predicted products shown.

In each case, the predicted product was the one chiefly formed.⁸⁰ The observation that *m*-aminoanisole is obtained, mentioned on p. 860, is also in accord with these predictions.

The Effect of the Leaving Group⁸¹

The common leaving groups in aliphatic nucleophilic substitution (halide, sulfate, sulfonate, NR_3^+ , etc.) are also common leaving groups in aromatic nucleophilic substitutions, but the groups NO_2 , OR, OAr, SO_2R ,⁸² and SR, which are not generally lost in aliphatic systems, are leaving groups when attached to aromatic rings. Surprisingly, NO_2 is a particularly good leaving group.⁸³ An approximate order of leaving-group ability is⁸⁴ $\text{F} > \text{NO}_2 > \text{OTs} > \text{SOPh} > \text{Cl}$, Br, I $> \text{N}_3 > \text{NR}_3^+ > \text{OAr}$, OR, SR, NH_2 . However, this depends greatly on the nature of the nucleophile, as illustrated by the fact that $\text{C}_6\text{Cl}_5\text{OCH}_3$ treated with NH_2^- gives mostly $\text{C}_6\text{Cl}_5\text{NH}_2$; that is, one methoxy group is replaced in preference to five chlorines.⁸⁵ As usual, OH can be a leaving group if it is converted to an inorganic ester. Among

the halogens, fluoro is generally a much better leaving group than the other halogens, which have reactivities fairly close together. The order is usually $\text{Cl} > \text{Br} > \text{I}$, but not always.⁸⁶ The leaving-group order is quite different from that for the $\text{S}_{\text{N}}1$ or $\text{S}_{\text{N}}2$ mechanisms. The most likely explanation is that the first step of the $\text{S}_{\text{N}}\text{Ar}$ mechanism is usually rate determining, and this step is promoted by groups with strong $-I$ effects. This would explain why fluoro and nitro are such good leaving groups when this mechanism is operating. Fluoro is the poorest leaving group of the halogens when the second step of the $\text{S}_{\text{N}}\text{Ar}$ mechanism is rate determining or when the benzyne mechanism is operating. The four halogens, as well as SPh , NMe_3^+ , and $\text{OPO}(\text{OEt})_2$, have been shown to be leaving groups in the $\text{S}_{\text{RN}}1$ mechanism.⁵⁵ The only important leaving group in the $\text{S}_{\text{N}}1$ mechanism is N_2^+ .

The Effect of the Attacking Nucleophile⁸⁷

It is not possible to construct an invariant nucleophilicity order because different substrates and different conditions lead to different orders of nucleophilicity, but an overall approximate order is $\text{NH}_2^- > \text{Ph}_3\text{C}^- > \text{PhNH}^-$ (aryne mechanism) $> \text{ArS}^- > \text{RO}^- > \text{R}_2\text{NH} > \text{ArO}^- > \text{OH}^- > \text{ArNH}_2 > \text{NH}_3 > \text{I}^- > \text{Br}^- > \text{Cl}^- > \text{H}_2\text{O} > \text{ROH}$.⁸⁸ As with aliphatic nucleophilic substitution, nucleophilicity is generally dependent on base strength and nucleophilicity increases as the attacking atom moves down a column of the periodic table, but there are some surprising exceptions, for example, OH^- , a stronger base than ArO^- , is a poorer nucleophile.⁸⁹ In a series of similar nucleophiles, such as substituted anilines, nucleophilicity is correlated with base strength. Oddly, the cyanide ion is not a nucleophile for aromatic systems, except for sulfonic acid salts and in the von Richter (13-30) and Rosenmund-von Braun (13-8) reactions, which are special cases.

REACTIONS

In the first part of this section, reactions are classified according to attacking species, with all leaving groups considered together, except for hydrogen and N_2^+ , which are treated subsequently. Finally, a few rearrangement reactions are discussed.

ALL LEAVING GROUPS EXCEPT HYDROGEN AND N₂⁺

A. Oxygen Nucleophiles

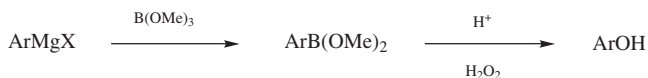

13-1 Hydroxylation of Aromatic Compounds

Hydroxy-de-halogenation

Aryl halides are converted to phenols if activating groups are present or if exceedingly strenuous conditions are employed.⁹⁰ When the reaction is carried out at high temperatures, cine substitution is observed, indicating a benzyne mechanism.⁹¹ The reaction has been done using NaOH on Montmorillonite K10 and AgNO₃ with microwave irradiation.⁹²

A slightly related reaction involves the amino group of naphthylamines can be replaced by a hydroxyl group by treatment with aqueous bisulfite.⁹³ The scope is greatly limited; the amino group (which may be NH₂ or NHR) must be on a naphthalene ring, with very few exceptions. The reaction is reversible (see **13-6**), and both the forward and reverse reactions are called the *Bucherer reaction*.

An indirect method for conversion of an aryl halide to a phenol involves initial conversion to an organometallic, followed by oxidation to the phenol. For the conversion of aryl Grignard reagents to phenols, a good procedure is the use of trimethyl borate followed by oxidation with H₂O₂ in acetic acid⁹⁴ (see **12-31**). Phenols have been obtained from unactivated aryl halides by treatment with borane and a metal such as lithium, followed by oxidation with alkaline H₂O₂.⁹⁵ Arylboronic acids, ArB(OH)₂, are oxidized by aqueous hydrogen peroxide to give the corresponding phenol.⁹⁶ The reaction of an aromatic compound with a borane in the

presence of an iridium catalyst, followed by oxidation with aqueous Oxone[®] gave the corresponding phenol.⁹⁷ Aryllithium reagents have been converted to phenols by treatment with oxygen.⁹⁸ In a related indirect method, arylthallium bis(trifluoroacetates) (prepared by **12-23**) can be converted to phenols by treatment with lead tetraacetate followed by triphenylphosphine and then dilute NaOH.⁹⁹ Diarylthallium trifluoroacetates undergo the same reaction.¹⁰⁰

OS I, 455; II, 451; V, 632. Also see, OS V, 918.

13-2 Alkali Fusion of Sulfonate Salts

Oxido-de-sulfonato-substitution

Aryl sulfonic acids can be converted, through their salts, to phenols, by alkali fusion. In spite of the extreme conditions, the reaction gives fairly good yields, except when the substrate contains other groups that are attacked by alkali at the fusion temperatures. Milder conditions can be used when the substrate contains activating groups, but the presence of deactivating groups hinders the reaction. The mechanism is obscure, but a benzyne intermediate has been ruled out by the finding that cine substitution does not occur.¹⁰¹

OS I, 175; III, 288.

13-3 Replacement by OR or OAr

Alkoxy-de-halogenation

This reaction is similar to **13-1** and, like that one, generally requires activated substrates.^{90,102} With unactivated substrates, side reactions predominate, though aryl methyl ethers have been prepared from unactivated chlorides by treatment with MeO⁻ in HMPA.¹⁰³ This reaction gives better yields than **13-1** and is

used more often. A good solvent is liquid ammonia. Aryl chlorides react with phenol and KOH with microwave irradiation to give the diaryl ether.¹⁰⁴ Potassium phenoxide reacts with iodobenzene in an ionic solvent at 100°C with CuCl.¹⁰⁵ The NaOMe reacted with *o*- and *p*-fluoronitrobenzenes $\sim 10^9$ times faster in NH₃ at -70°C than in MeOH.¹⁰⁶ Phase-transfer catalysis has also been used.¹⁰⁷ Phenols reacted with aryl fluorides with K₂CO₃/DMSO¹⁰⁸ or aryl chlorides with KOH,¹⁰⁹ with microwave irradiation, to give the diaryl ether. Aryl carbonates react with aryl oxides.¹¹⁰ Phenolic compounds react with aryl fluorides in the presence of LiOH in DMF to give the diaryl ether.¹¹¹ Aryl iodides react with phenols in the presence of K₂CO₃, CuI and Raney nickel alloy.¹¹²

In addition to halides, leaving groups can be other OR, and so on, even OH.¹¹³ Acid salts, RCOO⁻, are sometimes used as nucleophiles. Good yields of aryl benzoates can be obtained by the treatment of aryl halides with cuprous benzoate in diglyme or xylene at 140–160°C.¹¹⁴ Unactivated substrates have been converted to carboxylic esters in low-to-moderate yields under oxidizing conditions.¹¹⁵ The following chain mechanism, called the S_{ON}2 mechanism,¹¹⁶ has been suggested:¹¹⁵

For aroxide nucleophiles, the reaction is promoted by copper salts,¹¹⁷ and when these are used, activating groups need not be present. Indeed, unactivated aryl

halides, such as 4-iodoanisole, were coupled to allylic alcohols using a CuI catalyst in the presence of 2% 1,10-phenanthroline and cesium carbonate.¹¹⁸ This method of preparation of diaryl ethers is called the *Ullmann ether synthesis*¹¹⁹ and should not be confused with the Ullmann biaryl synthesis (13-11). The reactivity order is typical of nucleophilic substitutions, despite the presence of the copper salts.¹²⁰ Because aryloxycopper(I) reagents ArOCu react with aryl halides to give ethers, it has been suggested that they are intermediates in the Ullmann ether synthesis.¹²¹ Indeed, high yields of ethers can be obtained by reaction of ROCu or ArOCu with aryl halides.¹²² Alcohols, via the alkoxide, displace the halogen group in aryl halides to give aryl ethers in the presence of a palladium catalyst.¹²³ A palladium catalyzed, intramolecular displacement of an aryl halide with a pendant alkoxide unit leads to dihydrobenzofurans.¹²⁴ Nickel catalysts have also been used.¹²⁵ The reaction has been done by heating aryl iodides and phenols in an ionic liquid.¹²⁶

Unactivated substrates also react with phenoxide ion with electrochemical catalysis in liquid NH₃-Me₂SO, to give diaryl ethers, presumably by the S_{RN}I mechanism.¹²⁷ Diaryl ethers can be prepared from activated aryl halides by treatment with a triaryl phosphate, (ArO)₃PO.¹²⁸

Aryl thiols and thioethers can be prepared by reactions that are similar to **13-1** and **13-3**.¹²⁹ Activated aryl halides generally give good results, but side reactions are occasionally important. Some reagents give the thiol directly. 4-bromonitrobenzene reacts with Na₃SPO₃, in refluxing methanol, to give 4-nitrothiophenol.¹³⁰ Diaryl sulfides can be prepared by the use of ⁻SAr.¹³¹ Even unactivated aryl halides react with ⁻SAr if polar aprotic solvents, for example, DMF,¹³² DMSO¹³³ 1-methyl-2-pyrrolidinone,¹³⁴ or HMPA,¹³⁵ are used, though the mechanisms are still mostly or entirely nucleophilic substitution. 2-Iodothiophene reacts directly with thiophenol to give 2-phenylthiothiophene.¹³⁶ Unactivated aryl halides also give good yields of sulfides on treatment with ArS⁻ or RS⁻ (generated *in situ* from the corresponding thiol) in the presence of a palladium catalyst.¹³⁷ Copper catalysts have also been used.¹³⁸ Thiophenols were coupled to indoles in the presence of a vanadium catalyst.¹³⁹ Aryl iodides react with dialkyl disulfides and a nickel catalyst to give aryl alkyl sulfides.¹⁴⁰ Diaryl sulfides can also be prepared (in high yields) by treatment of unactivated aryl iodides with ArS⁻ in liquid ammonia under irradiation.¹⁴¹ The mechanism in this case is probably S_{RN}1. The reaction (with unactivated halides) has also been carried out electrolytically, with a nickel complex catalyst.¹⁴²

Arylboronic acids, (ArB(OH)₂), react with thiols and copper(II) acetate to give the corresponding alkyl aryl sulfide.¹⁴³ Arylboronic acids also react with *N*-methylthiosuccinimide, with a copper catalyst, to give the aryl methyl sulfide.¹⁴⁴ In the presence of a palladium catalyst, thiophenols react with diaryliodonium salts, Ar₂I⁺ BF₄⁻, to give the unsymmetrical diaryl sulfide.¹⁴⁵

Other sulfur nucleophiles also react with activated aryl halides:

Aryl sulfones have been prepared from sulfinic acid salts, aryl iodides and CuI.¹⁴⁶ Formation of thiocyanates from unactivated aryl halides has been accomplished with charcoal supported copper(I) thiocyanate.¹⁴⁷ The copper catalyzed reaction of NaO₂SMe and aryl iodides give the aryl methyl sulfone.¹⁴⁸ A similar synthesis of diaryl sulfones has been reported using a palladium catalyst.¹⁴⁹

An indirect method for the synthesis of aryl alkyl sulfides involves treatment of an aryl halide with butyllithium and then elemental sulfur. The resulting thiophenoxide anion reacts with an alkyl halide to give the targeted sulfide.¹⁵⁰

Aryl selenides (ArSeAr and ArSeAr') can be prepared by similar methodology. Symmetrical diaryl selenides were prepared by the reaction of iodobenzene with diphenyl diselenide (PhSeSePh), in the presence of Mg and a copper catalyst.¹⁵¹ Aryl halides react with tin selenides (ArSeSnR₃), with a copper catalyst, to give the diaryl selenide.¹⁵²

C. Nitrogen Nucleophiles

13-5 Replacement by NH₂, NHR, or NR₂

Amino-de-halogenation

Amido-de-halogenation

Activated aryl halides react quite well with ammonia and with primary and secondary amines to give the corresponding arylamines. Primary and secondary amines usually give better results than ammonia, with piperidine especially reactive. Picryl chloride (2,4,6-trinitrochlorobenzene) is often used to form amine derivatives. 2,4-Dinitrofluorobenzene is used to tag the amino end of a peptide or protein chain. Other leaving groups in this reaction may be NO₂,¹⁵³ N₃, OSO₂R, OR, SR, N=NAr (where Ar contains electron-withdrawing groups)¹⁵⁴ and even NR₂.¹⁵⁵

Aryl triflates were shown to react directly with secondary amines in *N*-methylpyrrolidine solvent using microwave irradiation.¹⁵⁶ Activated halides can be converted to diethylamino compounds $\text{ArX} \rightarrow \text{ArNMe}_2$ by treatment with HMPA.¹⁵⁷ Aniline derivatives react with activated aromatic rings, in the presence of tetrabutylammonium fluoride and under photolysis conditions, to give a *N,N*-diarylamine.¹⁵⁸ Arylation of amines with aryl halides has also been done in ionic liquids.¹⁵⁹

Unactivated aryl halides can be converted to amines by the use of NaNH_2 , NaNHR , or NaNR_2 .¹⁶⁰ Lithium dialkylamides also react with aryl halides to give the *N*-arylamine.¹⁶¹ With these reagents, the benzyne mechanism generally operates, so cine substitution is often found. The reaction of an amine, an aryl halide, and potassium *tert*-butoxide generates the *N*-aryl amine.¹⁶² *N*-Arylation was accomplished with butyllithium and a secondary amine using Ni/C-diphenylphosphinoferrrocene (dppf).¹⁶³ Ring closure has been effected by this type of reaction,¹⁶⁴ as in the conversion of **16** to the tetrahydroquinoline.

Larger rings can be prepared using this approach: 8 and even 12 membered. Triarylamines have been prepared in a similar manner from ArI and $\text{Ar}'_2\text{NLi}$, even with unactivated ArI .¹⁶⁵ In the *Goldberg reaction*, an aryl bromide reacts with an acetanilide in the presence of K_2CO_3 and CuI to give an *N*-acetyldiarylamine, which can be hydrolyzed to a diarylamine: $\text{ArBr} + \text{Ar}'\text{NHAc} \rightarrow \text{ArAr}'\text{NAC}$.¹⁶⁶ Aryl fluorides react in the presence of KF-alumina and 18-crown-6 in DMSO.¹⁶⁷ Lithium amides have been shown to react directly with aryl halides.¹⁶⁸ Aryl fluorides react

with amines in the presence of potassium carbonate/DMSO and ultrasound,¹⁶⁹ and aryl chlorides react on basic alumina with microwave irradiation.¹⁷⁰ 2-Chloronitrobenzene also reacts with aniline derivatives directly with microwave irradiation.¹⁷¹ 2-Fluoropyridine reacts with R₂NBH₃Li to give the 2-aminoalkylpyridine.¹⁷²

The reaction of amines with unactivated aryl halides requires a catalyst in most cases to initiate the reaction. There are several approaches that result in *N*-aryl amines, but recent work with aryl halides, amines, and palladium catalysts has proven quite useful.¹⁷³ Aryl halides react with amines (including aniline derivatives) in the presence of palladium catalysts to give the *N*-aryl amine.¹⁷⁴ Palladium catalysts have been used with aniline and or triflates¹⁷⁵ to give the secondary amine. Palladium catalysts have been used in conjunction with aryl halides and aliphatic amines–amide bases.¹⁷⁶ A considerable amount of work¹⁷⁷ has been done to vary the nature of the ligand and the palladium catalyst, as well as the base.¹⁷⁸ Aryl halides also react with aliphatic amines,¹⁷⁹ including cyclopropylamines,¹⁸⁰ and an intramolecular version of this reaction generates bicyclic amines (hydroindole derivatives).¹⁸¹ Primary aliphatic amines can be converted to tertiary *N,N*-diarylalkylamines in a two-step procedure using palladium catalysts.¹⁸² Aryl halides are

converted to *N,N*-diaryl tertiary amines by reaction with *N*-alkylaniline derivatives and a palladium catalyst.¹⁸³ Beginning with a primary aromatic amine and two different aryl halides (ArBr and Ar'Cl), a triarylamine with three different aryl groups can be prepared using a palladium catalyst.¹⁸⁴ Polymer-bound phosphine ligands have been used in conjunction with a palladium catalyst,¹⁸⁵ and polymer-bound amines have been *N*-arylated with a palladium catalyst followed by treatment with trifluoroacetic acid to release the aniline derivative.¹⁸⁶ Palladium-catalyzed aminoalkylation of aryl halides has been reported using microwave irradiation.¹⁸⁷ Aryl halides (Ar-X) have also been converted to the aniline derivative (Ar-NH₂) by reaction of the halide with an imine and a palladium catalyst, followed by hydrolysis.¹⁸⁸ Similarly, aniline derivatives have been prepared by the reaction of aryl chlorides with silylamines (Ph₃SiNH₂) using lithium hexamethyldisilazide and a palladium catalyst.¹⁸⁹ Amines react with Ph₂I⁺BF₄⁻, in the presence of palladium catalysts,¹⁹⁰ or a CuI catalyst¹⁹¹ to give the *N*-phenyl amine. These reactions have been done in ionic liquids using a palladium catalyst.¹⁹² Arylation of the amine unit of primary enamino ketones was accomplished using a palladium catalyst.¹⁹³ Mono-arylation of a 1,2-diamine is possible.¹⁹⁴ Aminoalkylation of heteroaromatic rings is possible, as in the reaction of 3-bromothiophene with a primary amine and a palladium catalyst.¹⁹⁵ 2-Halopyridines react to give the 2-aminoalkyl pyridine.¹⁹⁶ Carbazole derivatives were prepared from 2-iodoaniline and 2-trimethylsilylphenol *O*-triflates, using cesium fluoride and then a palladium catalyst.¹⁹⁷

Nickel catalysts have been used in the reaction of aryl halides with *N*-alkyl aniline derivatives.¹⁹⁸ Nickel catalyst also allow the conversion of aryl halides to *N*-arylamines via reaction with aliphatic amines.¹⁹⁹ An intramolecular reaction of a

pendant aminoalkyl unit with an aryl chloride moiety, catalyzed by nickel(0) gave a dihydroindole.²⁰⁰ Copper catalysts allow the reaction of diarylamines and aryl halides to give the corresponding triarylamines,²⁰¹ or with aliphatic amines to give the *N*-arylamines.²⁰² Aniline reacts with aryl iodides in a copper catalyst and potassium *tert*-butoxide to give triphenylamine.²⁰³ A polymer-bound copper catalyst was used in conjunction with aliphatic amines and arylboronic acids.²⁰⁴ Amino alcohols react with aryl iodides and a copper catalyst to give the *N*-arylamino alcohol.²⁰⁵ Treatment of alkylamines with arylboronic acids ArB(OH)₂ and Cu(OAc)₂ gave the *N*-aryl amine in 63% yield.²⁰⁶ Similar reaction with arylamines, such as aniline, gave the diarylamines.²⁰⁷ Arylboronic acids convert aziridines to *N*-arylaziridines,²⁰⁸ and amino esters to *N*-arylated amino esters,²⁰⁹ both reactions using a copper catalyst. An arylbismuth reagent reacts with aliphatic amines, in the presence of copper(II) acetate, to give an *N*-arylamines.²¹⁰ *N*-Arylation of pyrroles was accomplished by the reaction of an arylboronic acid and a copper catalyst.²¹¹ *N*-Arylindoles²¹² and *N*-arylimidazoles²¹³ were prepared from aryl halide using a copper catalyst. Diarylzinc reagents react with *N*-(OBz) amine derivatives, with a copper catalyst, to give the *N*-aryl amine.²¹⁴

In a related reaction, trifluoroarylboronates react with copper(II) acetate and then an aliphatic amine to give the *N*-phenylamine.²¹⁵

The metal catalyzed reaction with ammonia or amines likely proceeds by the S_NAr mechanism.²¹⁶ This reaction, with phase-transfer catalysis, has been used to synthesize triarylamines.²¹⁷ Copper ion catalysts (especially cuprous oxide or iodide) also permit the Gabriel synthesis (10-41) to be applied to aromatic substrates. Aryl bromides or iodides are refluxed with potassium phthalimide and

Cu_2O or CuI in dimethylacetamide to give *N*-aryl phthalimides, which can be hydrolyzed to primary aryl amines.²¹⁸

In certain cases, the $\text{S}_{\text{RN}}1$ mechanism has been found (p. 550). When the substrate is a heterocyclic aromatic nitrogen compound, still a different mechanism [the $\text{S}_{\text{N}}(\text{ANRORC})$ mechanism], involving opening and reclosing of the aromatic ring, has been shown to take place.²¹⁹

There are a number of indirect approaches for the preparation of aryl amines. Activated aromatic compounds can be directly converted to the *N*-aryl amine with hydroxylamine in the presence of strong bases.²²⁰ Conditions are mild and yields are high. Aryl halides can be converted to the corresponding Grignard reagent (**12-38**). Subsequent reaction of arylmagnesium halides with allyl azide ($\text{CH}_2=\text{CHCH}_2\text{N}_3$) followed by hydrolysis leads to the corresponding aniline derivative.²²¹ Aryl halides can be converted to the aryllithium via halogen–lithium exchange or hydrogen–lithium exchange (**12-38**, **12-39**). Molecular nitrogen (N_2) reacts with aryllithium compounds in the presence of compounds of such transition metals as titanium (e.g., TiCl_4), chromium, molybdenum, or vanadium to give (after hydrolysis) primary aromatic amines ($\text{ArLi} + \text{N}_2 + \text{transition metal salts} \rightarrow \text{ArNH}_2$, after hydrolysis).²²² Primary aromatic amines ArNH_2 were converted to diaryl amines ArNHPH by treatment with $\text{Ph}_3\text{Bi}(\text{OAc})_2$ ²²³ and a copper powder catalyst.²²⁴ Aryl Grignard reagents react with nitroaryl compounds to give, after reduction with $\text{FeCl}_3/\text{NaBH}_4$, a diaryl amine.²²⁵

The use of transition-metal catalysts allows aryl halides to react with the nitrogen of amides or carbamates, as well as amines, to give the corresponding *N*-aryl amide or *N*-aryl carbamate. Amides react with aryl halides in the presence of a palladium catalyst²²⁶ or a copper catalyst.²²⁷ *N*-Aryl lactams are prepared by the reaction of a lactam with an aryl halide in the presence of a palladium catalyst.²²⁸

See also, Ferraccioli, R.; Carenzi, D.; Rombolà, O.; Catellani, M. *Org. Lett.* **2004**, *6*, 4759.

β -Lactams also react.²²⁹ The reaction of 2-oxazolidinones with aryl halides in the presence of a palladium catalyst gave the *N*-aryl-2-oxazolidinone.²³⁰ Amides react with PhSi(OMe)₃/Cu(OAc)₂/Bu₄NF to give the *N*-aryl amide.²³¹ *N*-Boc hydrazine derivatives (BocNHNH₂) gave the *N*-phenyl derivative BocN(Ph)NH₂ when reacted with iodobenzene and a catalytic amount of CuI and 10% of 1,10-phenanthroline.²³² 3-Bromothiophene was converted to the 3-amido derivative with an amide and CuI-dimethylethylenediamine,²³³ and *N*-(2-thiophene)-2-pyrrolidinone was similarly prepared from 2-iodothiophene, the lactam and a copper catalyst.²³⁴ *N*-Arylation of urea is also possible using a copper catalyst.²³⁵ The reaction of a vinyl triflate with benzamide and a palladium catalyst gave the corresponding enamide (C=C–NHC=O).²³⁶

The transition-metal catalyzed couplings of primary or secondary phosphines with aryl halides or sulfonate esters to give arylphosphines is known.²³⁷ Palladium catalyzed conversion of aryl halides to aryl phosphines using (trimethylsilyl)diphenylphosphine is known, and tolerates many functional groups (not those that are easily reducible, such as aldehydes because zinc metal²³⁸ is often used as a coreagent), but it is mainly limited to aryl iodides.²³⁹ Diphenylphosphine reacts with aryl iodides and a copper catalyst to give the triarylphosphine.²⁴⁰ Aryl iodides also react with secondary phosphine and 5% Pd/C to give the *P*-arylphosphine.²⁴¹ Tertiary phosphines can also be used via aryl–aryl exchange, as in the reaction of an aryl triflate and triphenylphosphine and a palladium catalyst, for example, gave the arylphosphine (ArPPh₂).²⁴²

Arylsulfonic acid chlorides (ArSO₂Cl) have been shown to react with arylboronic acids, Ar'B(OH)₂, in the presence of a palladium catalyst, to give the corresponding biaryl (Ar–Ar').²⁴³

13-6 Replacement of a Hydroxy Group by an Amino Group Amino-de-hydroxylation

The reaction of naphthols with ammonia and sodium bisulfite⁸¹ is called the *Bucherer reaction*. Primary amines can be used instead of ammonia, in which case *N*-substituted naphthylamines are obtained. In addition, primary naphthylamines can be converted to secondary ($\text{ArNH}_2 + \text{RNH}_2 + \text{NaSO}_3 \rightarrow \text{ArNHR}$), by a transamination reaction. The mechanism of the Bucherer reaction amounts to a kind of overall addition–elimination, via **18** and **19**.²⁴⁴

The first step in either direction consists of addition of NaHSO_3 to one of the double bonds of the ring, which gives an enol from **17** (or enamine from **20**) that tautomerizes to the keto form **18** (or imine form, **19**). The conversion of **18** to **19** (or vice versa) is an example of **16-13** (or **16-2**). Evidence for this mechanism was the isolation of **18**²⁴⁵ and the demonstration that for β -naphthol treated with ammonia and HSO_3^- , the rate of the reaction depends only on the substrate and on

²⁴⁴Rieche, A.; Seeboth, H. *Liebigs Ann. Chem.* **1960**, 638, 66.

HSO₃⁻, indicating that ammonia is not involved in the rate-determining step.²⁴⁶ If the starting compound is a β-naphthol, the intermediate is a 2-keto-4-sulfonic acid compound, so the sulfur of the bisulfite in either case attacks meta to the OH or NH₂.²⁴⁷

Hydroxy groups on benzene rings can be replaced by NH₂ groups if they are first converted to aryl diethyl phosphates. Treatment of these with KNH₂ and potassium metal in liquid ammonia gives the corresponding primary aromatic amines.²⁴⁸ The mechanism of the second step is S_{RN}1.²⁴⁹

OS III, 78.

D. Halogen Nucleophiles

13-7 The Introduction of Halogens

Halo-de-halogenation, and so on.

It is possible to replace a halogen on a ring by another halogen²⁵⁰ if the ring is activated. In such cases there is an equilibrium, but it is usually possible to shift this in the desired direction by the use of an excess of added halide ion.²⁵¹ A phenolic hydroxy group can be replaced by chloro with PCl₅ or POCl₃, but only if activated. Unactivated phenols give phosphates when treated with POCl₃: 3 ArOH + POCl₃ → (ArO)₃PO. Phenols, even unactivated ones, can be converted to aryl bromides by treatment with Ph₃PBr₂²⁵² (see 10-47) and to aryl chlorides by treatment with PhPCl₄.²⁵³

Halide exchange is particularly useful for putting fluorine into a ring, since there are fewer alternate ways of doing this than for the other halogens. Activated aryl chlorides give fluorides when treated with KF in DMF, DMSO, or dimethyl sulfone.²⁵⁴ Reaction of aryl halides with Bu₄PF/HF is also effective for exchanging a halogen with fluorine.²⁵⁵ Halide exchange can also be accomplished with copper halides. Since the leaving-group order in this case is I > Br > Cl ≫ F (which means that iodides cannot normally be made by this method), the S_NAr mechanism is

²⁵⁵Uchibori, Y.; Umeno, M.; Seto, H.; Qian, Z.; Yoshioka, H. *Synlett* **1992**, 345.

probably not operating.²⁵⁶ However, aryl iodides have been prepared from bromides, by the use of Cu supported on charcoal or Al₂O₃,²⁵⁷ with an excess of NaI and a copper catalyst,²⁵⁸ and by treatment with excess KI and a nickel catalyst.²⁵⁹ Interestingly, aryl chlorides have been prepared from aryl iodides using 2 equivalents of NiCl₂ in DMF, with microwave irradiation.²⁶⁰

An indirect halogen exchange treated aryl bromides with *n*-butyllithium and the 5-(iodomethyl)- γ -butyrolactone, giving the aryl iodide and the lithium salt of 4-pentenoic acid.²⁶¹ Aryl iodides²⁶² and fluorides can be prepared from arylthallium bis(trifluoroacetates) (see **12-23**), indirectly achieving the conversions ArH \rightarrow ArI and ArH \rightarrow ArF. The bis(trifluoroacetates) react with KI to give ArI in high yields.²⁶³ Aryllead triacetates ArPb(OAc)₃ can be converted to aryl fluorides by treatment with BF₃-etherate.²⁶⁴ Treatment of PhB(OH)₂ with *N*-iodosuccinimide gives iodobenzene.²⁶⁵ Arylboronic acids (**12-28**) can be converted to the corresponding aryl bromides by reaction with 1,3-dibromo-5,5-dimethylhydantoin and 5 mol % NaOMe.²⁶⁶ Other aryl halides can be prepared using 1,3-dihalo-5,5-dimethylhydantoin.

OS III, 194, 272, 475; V, 142, 478; VIII, 57; **81**, 98.

The reduction of phenols and phenolic esters and ethers is discussed in Chapter 19 (see **19-38** and **19-35**). The reaction ArX \rightarrow ArH is treated in Chapter 11 (reaction **11-39**), although, depending on reagent and conditions, it can be nucleophilic or free-radical substitution, as well as electrophilic.

E. Carbon Nucleophiles²⁶⁷

Some formations of new aryl-carbon bonds formed from aryl substrates have been considered in Chapter 10 (see **10-57**, **10-68**, **10-76**, **10-77**).

13-8 Cyanation of Aromatic Rings

Cyano-de-halogenation

Cyano-de-metalation

The reaction between aryl halides and cuprous cyanide is called the *Rosenmund-von Braun reaction*.²⁶⁸ Reactivity is in the order I > Br > Cl > F, indicating that the S_NAr mechanism does not apply.²⁶⁹ Other cyanides (e.g., KCN and NaCN) do not react with aryl halides, even activated ones. This reaction has been done in ionic liquids using CuCN.²⁷⁰ The reaction has also been done in water using CuCN, a phase transfer catalyst, and microwave irradiation.²⁷¹

Aryl halides reaction with metal cyanides, often with another transition metal catalyst, to give aryl nitriles (aryl cyanides). Aryl halides react with Zn(CN)₂ and a palladium catalyst, for example, to give the aryl nitrile.²⁷² Similarly, aryl iodides react with CuCN and a palladium catalyst to give the aryl nitrile.²⁷³ Potassium cyanide (KCN) reacts in a similar manner with a palladium catalyst.²⁷⁴ Sodium cyanide has been used with a copper catalyst and 20% KI.²⁷⁵ The reaction of aryl iodides and sodium cyanoborohydride/catechol, with a palladium catalyst, generates the aryl nitrile.²⁷⁶ Aryl bromides react with Ni(CN)₂ with microwave irradiation to give ArCN.²⁷⁷ In general, alkali cyanides do convert aryl halides to nitriles²⁷⁸ in dipolar aprotic solvents in the presence of Pd(II) salts²⁷⁹ or copper²⁸⁰ or nickel²⁸¹

complexes. A nickel complex also catalyzes the reaction between aryl triflates and KCN to give aryl nitriles.²⁸²

Arylthallium bis(trifluoroacetates) (see **12-23**) can be converted to aryl nitriles by treatment with copper(I) cyanide in acetonitrile.²⁸³ Another procedure uses excess aqueous KCN followed by photolysis of the resulting complex ion $\text{ArTl}(\text{CN})_3^-$ in the presence of excess KCN.²⁸⁴ Alternatively, arylthallium acetates react with $\text{Cu}(\text{CN})_2$ or CuCN to give aryl nitriles.²⁸⁵ Yields from this procedure are variable, ranging from almost nothing to 90 or 100%. Aromatic ethers ArOR ²⁸⁶ have been photochemically converted to ArCN .

An indirect method involves the reaction of an aromatic ring with *tert*-butyllithium, particularly when there is a directing group (see **13-17**), followed by reaction with PhOCN (phenyl cyanate) to give the aryl nitrile.²⁸⁷ Another indirect method involves the palladium catalyzed reaction of aryl bromides with the cyanohydrin of acetone [$\text{Me}_2\text{C}(\text{OH})\text{CN}$] to give ArCN .²⁸⁸

OS III, 212, 631.

13-9 Coupling of Aryl and Alkyl Organometallic Compounds with Aryl Halides, Ethers, and Carboxylic Esters

Aryl-de-halogenation, and so on

A number of methods involving transition metals have been used to prepare unsymmetrical biaryls (see also, **13-11**). The uncatalyzed coupling of aryl halides and metalated aryls (particularly aryllithium reagents) is also known, including cyclization of organolithium reagents to aromatic rings.²⁸⁹ Noncatalyzed coupling reactions of aryllithium reagents and haloarenes can proceed via the well-known aryl route but in some cases, a novel addition-elimination pathway is possible when substituents facilitate a chelation-driven nucleophilic substitution pathway.²⁹⁰ Such noncatalyzed coupling reactions often proceed with high regioselectivity and high yield.²⁹⁰ Several noncatalyzed alternative routes are available. 2-Bromopyridine reacts with pyrrolidine, at 130°C with microwave irradiation, to give 2-(2-pyrrolidino)pyridine.²⁹¹ Aryl iodides undergo homo-coupling to give the biaryl by

heating with triethylamine in an ionic liquid.²⁹² Arylsiloxanes react with aryl halides, for example, to give the biaryl derivative.²⁹³ The reaction of NaBPh₄ (sodium tetraphenylborate) and a silyl dichloride (Ph₂SiCl₂) gives biphenyl.²⁹⁴

There are many catalytic methods. A homo-coupling type reaction was reported in which PhSnBu₃ was treated with 10% CuCl₂, 0.5 equivalents of iodine and heated in DMF to give biphenyl.²⁹⁵ Arylsulfonyl chlorides also react with ArSnBu₃ with palladium and copper catalysts to give the biaryl.²⁹⁶ Aryl halides undergo homo-coupling to give the biaryl with a palladium catalyst²⁹⁷ or a nickel catalyst.²⁹⁸ In general, aryl tin compounds couple with aryl halides.²⁹⁹ An aryltin-aryl halide coupling has been done in ionic liquids.³⁰⁰ Aryl iodides have been coupled to form symmetric biphenyls using Pd(OAc)₂³⁰¹ and self-coupling occurs with aryl triflates under electrolysis conditions with a palladium catalyst.³⁰² A “double-coupling” reaction involving 2-trimethylsilylphenol *O*-triflate, allyltributyltin and allyl chloride, with CsF and a palladium catalyst, gave 1,2-diallylbenzene.³⁰³ Another homo-coupling reaction of pyridyl bromides was reported using NiBr₂ under electrolytic conditions.³⁰⁴ Thiophene derivatives,³⁰⁵ pyrrole,³⁰⁶ azoles,³⁰⁷ quinoline,³⁰⁸ and indolizine³⁰⁹ have been coupled to aryl halides using a palladium catalyst.

Grignard reagents couple with aryl halides without a palladium catalyst, by the benzyne mechanism,³¹⁰ but an iron catalyzed coupling reaction was reported,³¹¹ as

the presence of palladium(II) acetate³⁵⁰ or a nickel catalyst.³⁵¹ Vinylboronic acids coupled to aryl halides to give the vinyl coupling product.³⁵² Vinylboronic acids have been coupled to aryl diazonium salts (**13-25**) without added base, using a palladium catalyst with an imidazolium ligand.³⁵³

Alkyltrifluoroborates (RBF₃K, see **12-28**) react with aryl triflates³⁵⁴ or aryl halides,³⁵⁵ or aryl iodonium salts³⁵⁶ with a palladium catalyst, to give the arene. The reaction is compatible with sensitive functionality, such as an epoxide unit.

It is possible to couple metalated alkyl compounds to aryl compounds. The lithium enolate anion of an ester was coupled to an aryl halide, for example, using a palladium catalyst.³⁵⁷

Chiral vinyl sulfoxides have been coupled to aryl iodides to give a chiral allylic aryl compounds (C=C-CH₂-Ar), in a three-step procedure with good enantioselectivity.³⁵⁸

The reaction of a cyclic zirconium–diene complex and an aryl diiodide, with CuCl, leads to highly substituted naphthalene derivatives.³⁵⁹

OS VI, 916; VIII, 430, 586; X, 9, 448.

13-10 Arylation and Alkylation of Alkenes

Alkylation or Alkyl-de-hydrogenation, and so on

Arylation of alkenes can also be achieved³⁶⁰ by treatment with an “arylpalladium” reagent, typically generated *in situ* from an aryl halide or other suitably functionalized aromatic compound and a palladium(0) catalyst.³⁶¹ Other methods

are available for this arylation reaction.³⁶² Treatment of an arylmercury compound (either Ar₂Hg or ArHgX) with LiPdCl₃ (ArHgX → “ArPdX”) can generate the appropriate intermediate,³⁶³ and in some cases other noble metal salts have been used. The palladium catalyzed aryl–alkene coupling reaction is known as *the Heck reaction*. The reaction works best with aryl iodides, although conditions have been developed for aryl bromides and aryl chlorides.³⁶⁴ Aryldiazonium salts (**13-25**), rather than aryl halides, have also been used in the Heck reaction.³⁶⁵ When 2,3,4,5,6-pentafluorobromobenzene was used as a substrate, coupling occurred via the bromine, giving the pentafluorophenyl alkene.³⁶⁶ Aryl halides bearing ortho-substituents also under the coupling reaction.³⁶⁷ Heteroaryl halides can be used in the couple reaction.³⁶⁸ Note that acetanilide derivatives reacted with conjugated esters to give the Heck product in acetic acid using a palladium catalyst.³⁶⁹ Other activated aromatic compounds couple in a similar manner using palladium catalysts³⁷⁰ unactivated aromatic compounds using special reaction conditions.³⁷¹

Unlike **13-26**, the Heck reaction is not limited to activated substrates. The substrate can be a simple alkene, or it can contain a variety of functional groups, such as ester, ether,^{372,373} carboxyl, phenolic, or cyano groups.³⁷⁴ Coupling with vinyl ethers has been reported, C=C–OR → C=C(Ar)OR.³⁷⁵ The Heck reaction can be done with heterocyclic compounds,³⁷⁶ and the C–C unit of compounds, such as indene, react with aryl iodides and palladium catalyst without the need for

preparing the halide.³⁷⁷ The Heck reaction has also been performed intramolecularly.³⁷⁸ Asymmetric Heck reactions are known³⁷⁹ and the effects of high pressure have been studied.³⁸⁰

Ethylene is the most reactive alkene. Increasing substitution lowers the reactivity. Substitution therefore takes place at the less highly substituted side of the double bond.³⁸¹ The aryl halide or aryl triflate can be coupled to dienes,³⁸² allenes,³⁸³ allylic silanes,³⁸⁴ allylic amines,³⁸⁵ vinyl phosphonate esters,³⁸⁶ and with terminal alkynes.³⁸⁷ Alkylation can also be accomplished, but only if the alkyl group lacks a β -hydrogen, for example, the reaction is successful for the introduction of methyl, benzyl, and neopentyl groups.³⁸⁸ However, vinylic groups, even those possessing β -hydrogens, have been successfully introduced (to give 1,3-dienes) by the reaction of the alkene with a vinylic halide in the presence of a trialkylamine and a palladium(0) catalyst.³⁸⁹ Aryl iodides can be coupled to 1-methyl-1-vinyl- and 1-methyl-1-(prop-2-enyl)silacyclobutane with desilylation, using a palladium catalyst and Bu_4NF , to give the corresponding styrene derivative.³⁹⁰ Indene reacts with iodobenzene with a palladium catalyst to give the phenylindene (80:20 C3/C2).³⁹¹

Control of regiochemistry is a serious problem in the addition to unsymmetrical alkenes. Some regioselectivity can be obtained by the use of alkenes attached to an

auxiliary coordinating group,³⁹² the use of special ligands and acrylate or styrene as substrates.³⁹³ Steric effects are thought to control regioselectivity,³⁹⁴ but electronic influences have also been proposed.³⁹⁵ It has been shown that the presence of steric effects generally improve 1,2-selectivity, and that electronic effects can be used to favor 1,2- or 2,1-selectivity.³⁹⁶

Phosphine free catalysts³⁹⁷ and halogen-free reactions³⁹⁸ are known for the Heck reaction. Improvements on the palladium catalyst system are constantly being reported,³⁹⁹ including polymer-supported catalysts.⁴⁰⁰ The influence of the ligand has been examined.⁴⁰¹ Efforts have been made to produce a homogeneous catalyst for the Heck reaction.⁴⁰² The Heck reaction can be done in aq. media,⁴⁰³ in perfluorinated solvents,⁴⁰⁴ in polyethylene glycol,⁴⁰⁵ in neat tricaprilmethylammonium

chloride,⁴⁰⁶ and in supercritical CO₂ (see p. 414).⁴⁰⁷ A noncatalytic reaction was reported using supercritical water.⁴⁰⁸ The reaction has been done on solid support,⁴⁰⁹ including Montmorillonite clay,⁴¹⁰ glass beads,⁴¹¹ on a reverse-phase silica support,⁴¹² and using microwave irradiation.⁴¹³ A microwave irradiated Heck coupling was done in water using a palladium catalyst.⁴¹⁴ The Heck reaction has also been in ionic liquids,⁴¹⁵ and it is known that the nature of the halide is important in such reactions.⁴¹⁶

The evidence is in accord with an addition–elimination mechanism (addition of ArPdX followed by elimination of HPdX) in most cases.⁴¹⁷ In the conventionally accepted reaction mechanism,⁴¹⁸ a four-coordinate aryl–Pd(II) intermediate is formed by oxidative addition of the aryl halide to a Pd(0) complex prior to olefin addition. This suggests that cleavage of the dimeric precursor complex, reduction of Pd²⁺, and ligand dissociation combine to give a viable catalytic species.⁴¹⁹ If these processes occur on a time scale comparable to that of the catalytic reaction, non-steady-state catalysis could occur while the active catalyst is forming, and an

analysis of reaction kinetics under dry conditions was reported.⁴¹⁹ In this study, the mechanism requires a first-order dependence on olefin concentration, and anomalous kinetics may be observed when the rate-limiting step is not directly on the catalytic cycle.⁴¹⁹

The reactions are stereospecific, yielding products expected from syn addition followed by syn elimination.⁴²⁰ Because the product is formed by an elimination step, with suitable substrates double bond migration can occur, resulting in allylic rearrangement (as in the reaction of cyclopentene and iodobenzene to give **21**).⁴²¹ Primary and secondary allylic alcohols (and even non-allylic unsaturated alcohols⁴²²) give aldehydes, such as **22** or ketones that are products of double-bond migration.⁴²³ Similarly, dihydrofurans react with aryl triflates and a palladium catalyst that includes a chiral ligand, to give the 5-phenyl-3,4-dihydrofuran with good enantioselectivity.⁴²⁴ A similar reaction was reported for an *N*-carbamoyl dihydropyrrole.⁴²⁵ It has been reported that double bond isomerization can be suppressed in intramolecular Heck reactions done in supercritical CO₂ (see p. 414).⁴²⁶ The mechanistic implications of asymmetric Heck reactions has been examined.⁴²⁷

There are a number of variations of this reaction, including the use of transition metal catalyst other than palladium. A silane-tethered, intramolecular Heck reaction has been reported.⁴²⁸ Arylphosphonic acids, ArP(=O)(OH)₂, couple to aryl alkenes in the presence of a palladium catalyst.⁴²⁹ Aryl halides couple with vinyl

13-11 Homo-Coupling of Aryl Halides: The Ullmann Reaction

De-halogen-coupling

The coupling of aryl halides with copper is called the *Ullmann reaction*.⁴⁵⁵ The reaction is clearly related to **13-9**, but involves aryl copper intermediates. The reaction is of broad scope and has been used to prepare many symmetrical and unsymmetrical biaryls.⁴⁵⁶ When a mixture of two different aryl halides is used, there are three possible products, but often only one is obtained. For example, picryl chloride and iodobenzene gave only 2,4,6-trinitrobiphenyl.⁴⁵⁷ The best leaving group is iodo, and the reaction is most often done on aryl iodides, but bromides, chlorides, and even thiocyanates have been used.

The effects of other groups on the ring are unusual. The nitro group is strongly activating, but only in the ortho (not meta or para) position.⁴⁵⁸ Both R and OR groups activate in all positions. Not only do OH, NH₂, NHR, and NHCOR inhibit

the reaction, as would be expected for aromatic nucleophilic substitution, but so do COOH (but not COOR), SO₂NH₂, and similar groups for which the reaction fails completely. These groups inhibit the coupling reaction by causing side reactions.

The mechanism is not known with certainty. It seems likely that it is basically a two-step process, similar to that of the Wurtz reaction (10-56), which can be represented schematically by

Organocopper compounds have been trapped by coordination with organic bases.⁴⁵⁹ In addition, aryl copper compounds (ArCu) have been independently prepared and shown to give biaryls (Ar-Ar') when treated with aryl iodides Ar'I.⁴⁶⁰ A similar reaction has been used for ring closure:⁴⁶¹

An important alternative to the Ullmann method is the use of certain nickel complexes.⁴⁶² This method has also been used intramolecularly.⁴⁶³ Aryl halides ArX can also be converted to Ar-Ar⁴⁶⁴ by treatment with activated Ni metal,⁴⁶⁵ with Zn and nickel complexes,⁴⁶⁶ with aqueous alkaline sodium formate, Pd-C, and a phase-transfer catalyst,⁴⁶⁷ and in an electrochemical process catalyzed by a nickel complex.⁴⁶⁸

An asymmetric Ullmann reaction has also been reported.⁴⁶⁹

The palladium-catalyzed coupling of aryl halides and other aryl substrates with aromatic rings containing a suitable leaving group is now well established. Other nucleophiles can be coupled to aryl halides.⁴⁷⁰ The reaction has become so significant in organic chemistry that the transformations have been categorized as named reactions, and are discussed in Sections 13-14 and 13-15.

13-12 Coupling of Aryl Compounds With Arylboronic acid Derivatives

Aryl-de-halogenation, and so on **Aryl-de-boronylation**, and so on

Aryl triflates react with arylboronic acids, ArB(OH)₂ (**12-28**),⁴⁷¹ or with organoboranes,⁴⁷² in the presence of a palladium catalyst,⁴⁷³ to give the arene in what is called *Suzuki coupling* (or *Suzuki-Miyaura coupling*).⁴⁷⁴ Aryl halides are commonly used, and aryl sulfonates have been used.⁴⁷⁵ Even hindered boronic acids give good yields of the coupled product.⁴⁷⁶ Homo-coupling of arylboronic acids has been reported.⁴⁷⁷ Coupling of the alkynes to form a diyne (see **14-16**) can be a problem in some cases, although the aryl-alkyne coupling usually predominates.⁴⁷⁸ Some aromatic compounds are so reactive that a catalyst may not be required. Using tetrabutylammonium bromide, phenylboronic acid was coupled to 2-bromofuran without a catalyst.⁴⁷⁹

CO₂⁴⁹² (see p. 414), and in water with microwave irradiation⁴⁹³ or in water with a palladium catalyst, air, and tetrabutylammonium fluoride.⁴⁹⁴ A solvent free (neat) Suzuki reactions have been reported.⁴⁹⁵ A variety of functional groups are compatible with Suzuki coupling, including Ar₂P=O,⁴⁹⁶ CHO,⁴⁹⁷ C=O of a ketone,⁴⁹⁸ CO₂R,⁴⁹⁹ cyclopropyl,⁵⁰⁰ NO₂,⁵⁰¹ CN,⁴⁸⁸ and halogen substituents.⁵⁰²

There are many structural variations of the reaction that give it enormous synthetic potential. Halogenated heteroaromatic compounds react. 2-Halopyridines react with arylboronic acids and a palladium catalyst to give 2-arylpyridines.⁵⁰³ Other heterocycles have been similarly arylated.⁵⁰⁴ 4-Pyridylboronic acids have been used.⁵⁰⁵ The reaction of phenylboronic acid and a diallyl amide which contained a vinyl bromide, led to ring closure as well as incorporation of the phenyl group, give an *N*-tosylpyrrolidine with an exocyclic methylene unit.⁵⁰⁶ Vinyl halides react with arylboronic acids to give alkenyl derivatives (vinyl arenes, C=C-Ar).⁵⁰⁷ Alkylation can accompany arylation if alkyl halides are added, as in the conversion of iodobenzene to 2,6-dibutylbiphenyl.⁵⁰⁸

⁵⁰⁸Catellani, M.; Motti, E.; Minari, M. *Chem. Commun.* **2000** 157. For a different approach using aryl halides having a phosphonate ester group, see Yin, J.; Buchwald, S.L. *J. Am. Chem. Soc.* **2000**, *122*, 12051.

Since many biaryls are chiral due to atropisomerism (see p. 147), the use of a chiral catalyst, and/or a chiral ligand can lead to enantioselectivity in the Suzuki coupling.⁵⁰⁹

Arylsulfonates can be coupled to aryl triflates using a palladium catalyst,⁵¹⁰ and arylboronic acids couple with aryl sulfonate esters.⁵¹¹ Aryl boronic acids are coupled with aryl ammonium salts to give the biaryl, with a nickel catalyst.⁵¹² Allylic acetates have been coupled to arylboronic acids using nickel bis(acetylacetonate) and diisobutylaluminum hydride.⁵¹³ Aryl halides couple with $\text{ArB}(\text{IR}'_2)$ species with a palladium catalyst.⁵¹⁴ Arylboronic acids couple with the phenyl group of Ph_2TeCl_2 with a palladium catalyst.⁵¹⁵ 3-Iodopyridine reacted with NaBPh and palladium acetate, with microwave irradiation, to give 3-phenylpyridine.⁵¹⁶ Tributyltinaryl compounds were coupled to the aryl group of $\text{Ar}_2\text{I}^+\text{BF}_4^-$ with a nickel catalyst.⁵¹⁷ Organoboranes are coupled to aryl halides with a palladium catalyst.⁵¹⁸ Aryl silanes can be coupled to aryl iodides using Ag_2O and a palladium catalyst,⁵¹⁹ and arylsiloxanes $\text{ArSi}(\text{OR})_3$, are coupled to aryl halides with Bu_4NF and a palladium catalyst.⁵²⁰

Arylborates (**12-28**), $\text{ArB}(\text{OR})_2$, can be used in place of the boronic acid. The coupling reaction of aryl iodide **23** with boronate **24**, for example, gave the biaryl.⁵²¹ Aryl and heteroarylboroxines (**25**) can be coupled to aryl halides using a palladium catalyst.⁵²²

For a mechanistic viewpoint,⁵²³ the Suzuki coupling proceeds via oxidative addition of areneboronic acids to give a $\text{Pd}(0)$ species, followed by 1,2 arene migration to an electron-deficient palladium atom, eventually leading to very fast reductive

elimination to afford biaryls.⁵²⁴ Several intermediates of the oxidative coupling process have been identified by electrospray ionization mass spectrometry.⁵²⁵

25

A Suzuki-type coupling reaction has been reported involving acyl halides. When arylboronic acids were reacted with benzoyl chloride and PdCl₂, the product was the diaryl ketone.⁵²⁶ This coupling reaction was also accomplished using a palladium(0) catalyst.⁵²⁷ Cyclopropylboronic acids couple with benzoyl chloride, in the presence of Ag₂O and a palladium catalyst, to give the cyclopropyl ketone.⁵²⁸ A nickel catalyst has been used,⁵²⁹ and Ph₃P/Ni/C–BuLi has also been used.⁵³⁰ Arylboronic acids have also been coupled to anhydrides,⁵³¹ and the methoxy group of anisole derivatives has been replaced with phenyl using phenylboronic acid and a ruthenium catalyst.⁵³²

In a related reaction, aryltrifluoroborates PhBF₃⁺ X[–] (**12-28**), are coupled to aryl halides with a palladium catalyst to give the biaryl.⁵³³

13-13 Aryl–Alkyne Coupling Reactions

Alkynyl-de-halogenation, and so on

When aryl halides react with copper acetylides to give 1-aryl alkynes, the reaction is known as *Stephens–Castro coupling*.⁵³⁴ Both aliphatic and aromatic

substituents can be attached to the alkyne unit, and a variety of aryl iodides has been used. Benzonitrile was shown to react with alkynyl zinc bromides, with a nickel catalyst and after electrolysis to give the diarylalkyne, where the cyano unit was replaced with an alkyne unit.⁵³⁵

A palladium-catalyzed variation is also known in which an aryl halide reacts with a terminal alkyne to give 1-aryl alkynes is called the *Sonogashira coupling*.⁵³⁶ Terminal aryl alkynes react with aryl iodides and palladium(0)⁵³⁷ to give the corresponding diaryl alkyne.⁵³⁸ As with all of the metal-catalyzed reactions in this chapter, work has been done to vary reaction conditions, including the catalyst,⁵³⁹ the ligand, the solvent,⁵⁴⁰ and additives.⁵⁴¹ copper-free palladium/DABCO catalysts have been used.⁵⁴² Aryl iodides are more reactive than aryl fluorides.⁵⁴³ Alkynes can be coupled to heteroaromatic compounds via the heteroaryl halide.⁵⁴⁴ The coupling reaction has been done neat, with microwave irradiation on KF-alumina,⁵⁴⁵ and in aqueous polyethylene glycol.⁵⁴⁶ The aryl-alkyne coupling has also been done in solution with microwave irradiation.⁵⁴⁷ Sonogashira coupling

was reported on microbeads,⁵⁴⁸ with nanoparticulate nickel powder,⁵⁴⁹ and the aryl iodide was tethered to a polymer for a solid-state reaction that included the use of microwave irradiation, and cleavage from the polymer using trifluoroacetic acid.⁵⁵⁰ Polymer supported catalysts are known.⁵⁵¹ Conversion of 1-lithioalkynes to the corresponding alkynyl zinc reagent allows coupling with aryl iodides when a palladium catalyst is used.⁵⁵² Coupling with alkynyl tin compounds is also known.⁵⁵³ The 1-lithioalkyne was directly coupled to aryl bromides in the presence of B(OiPr)₃ and a palladium catalyst,⁵⁵⁴ where an alkynylboronic acid was generated *in situ*.

A variation was reported with environmental importance, where the triphenylphosphine by-product was scavenged by addition of Merrifield resin.⁵⁵⁵ A copper-free Sonogashira coupling has been reported, in triethylamine⁵⁵⁶ and in an ionic liquid.⁵⁵⁷ A copper and amine-free reaction was reported in normal solvents, such as THF.⁵⁵⁸ An interesting example of the versatility of the coupling reaction is the coupling of propargyl bromide and an aryl iodide, in the presence of an amine, giving the aryl aminomethylalkyne.⁵⁵⁹ The coupling of 4-chloroacetophenone with 1-phenylethyne shows that the carbonyl group is compatible with this reaction.⁵⁶⁰

Diaryliodonium salts react with terminal alkynes to give the phenyl alkyne.⁵⁶¹ A variation couples the phenyl group of Ph₂I⁺OTf⁻ with an en-yne using a palladium catalyst.⁵⁶² Aryl sulfonate esters can be coupled to terminal alkynes using a palladium catalyst in polymethylhydrosiloxane.⁵⁶³ Aryl halides are coupled to alkynyl-trifluoroborates (R–C≡C–BF₃K, **12-28**) using a palladium catalyst.⁵⁶⁴ The boron trifluoride induced palladium-catalyzed cross-coupling reaction of 1-aryltriazenes with areneboronic acids has been reported.⁵⁶⁵

A variation of this aryl–alkyne coupling reaction reacted methylthioalkynes (R–C≡C–SMe) with arylboronic acids and a palladium catalyst to give the aryl alkyne (R–C≡C–Ar).⁵⁶⁶ 1-Trialkylsilylalkynes (R₃Si–C≡C–R') were coupled

to aryl iodides using a palladium catalyst.⁵⁶⁷ A triphenylstibine, $\text{Ph}_3\text{Sb}(\text{OAc})_2$, was used to transfer a phenyl group to the alkyne carbon of $\text{PhC}\equiv\text{CSiMe}_3$, using palladium and CuI catalysts.⁵⁶⁸ Aryl iodides were also coupled to lithium alkynyl borate complexes, $\text{Li}[\text{R}-\text{C}\equiv\text{C}-\text{B}(\text{OR}')_3]$, to give the aryl alkyne.⁵⁶⁹ Note that diphenylethyne was prepared from bromobenzene and 2-chloro-1-bromoethane using KOH , 18-crown-6 and a palladium catalyst.⁵⁷⁰

13-14 Arylation at a Carbon Containing an Active Hydrogen

Bis(ethoxycarbonyl)methyl-de-halogenation, and so on

The arylation of compounds of the form $\text{ZCH}_2\text{Z}'$ is analogous to **10-67**, where Z is as defined as an electron withdrawing group (ester, cyano, sulfonyl, etc.). Activated aryl halides generally give good results.⁵⁷¹ Even unactivated aryl halides can be employed if the reaction is carried out in the presence of a strong base, such as NaNH_2 ⁵⁷² or LDA . Compounds of the form $\text{ZCH}_2\text{Z}'$, even simple ketones⁵⁷³ and carboxylic esters have been arylated in this manner. The reaction with unactivated halides proceeds by the benzyne mechanism and represents a method for extending the malonic ester (and similar) syntheses to aromatic compounds. The base performs two functions: it removes a proton from $\text{ZCH}_2\text{Z}'$ and catalyzes the benzyne mechanism. The reaction has been used for ring closure, as in the formation of **26**.⁵⁷⁴

Res.* **1989**, *22*, 275; Hoffmann, R.W. *Dehydrobenzene and Cycloalkynes*, Academic Press, NY, **1967**, pp. 150–164. See also, Kessar, S.V. *Acc. Chem. Res.* **1978**, *11*, 283.

The coupling of active methylene compounds and unactivated aryl halides can also be done with copper halide catalysts⁹³ (the *Hurtley reaction*).⁵⁷⁵ A palladium catalyst can be used for the coupling of malonate esters with unactivated aryl halides.⁵⁷⁶ Bis(sulfones), CH₂(SO₂Ar)₂, react with aryl halides in the presence of a palladium catalyst.⁵⁷⁷ Similar coupling was accomplished with CH₂(CN)₂ and a nickel catalyst.⁵⁷⁸ Malonic and β-keto esters can be arylated at the α-carbon in high yields by treatment with aryllead tricarboxylates [ArPb(OAc)₃],⁵⁷⁹ and with triphenylbismuth carbonate (Ph₃BiCO₃)⁵⁸⁰ and other bismuth reagents.⁵⁸¹ In a related process, manganese(III) acetate was used to convert a mixture of ArH and ZCH₂Z' to ArCHZZ'.⁵⁸²

The reaction of the enolate anions ketones and aldehydes, generated *in situ* by addition of a suitable base, with aryl halides can be accomplished by treatment with a palladium catalyst.⁵⁸³ Formation of an enolate anion of a conjugated ketone (cyclohexenone) via reaction with LDA (see p. 389), in the presence of Ph₃BiCl₂, leads to the α-phenyl conjugated ketone (6-phenylcyclohex-2-enone).⁵⁸⁴ An ester reacted with TiCl₄ and *N,N*-dimethylaniline to give the para-substitution product. (Me₂N—Ar—CHRCO₂Et).⁵⁸⁵ The enolate anion of lactams will react with aryl halides in the presence of a palladium catalyst go via the 3-aryl lactam.⁵⁸⁶ When the enolate anion of a ketone is generated in the presence of a palladium catalyst and a chiral phosphine ligand, the α-aryl ketone is formed with good enantioselectivity.⁵⁸⁷

Compounds of the form CH₃Z can be arylated by treatment with an aryl halide in liquid ammonia containing Na or K, as in the formation of **27** and **28**.⁵⁸⁸

When the solution is irradiated with near-UV light, but Na or K is omitted, the same products are obtained (though in different proportions).⁵⁸⁹ In either case, other leaving groups can be used instead of halogens (e.g., NR_3^+ , SAr) and the mechanism is the $\text{S}_{\text{RN}}1$ mechanism. Iron(II) salts have also been used to initiate this reaction.⁵⁹⁰ The reaction can also take place without an added initiator. The reaction of 2-fluoroanisole and KHMDS, and 4 equivalents of 2-cyanopropane, leads to substitution of the fluorine atom by CMe_2CN .⁵⁹¹ A similar reaction as reported using a palladium catalyst.⁵⁹² Nitroethane was converted to 2-phenylnitroethane using bromobenzene and a palladium catalyst.⁵⁹³

Enolate ions of ketones react with PhI in the dark.⁵⁹⁴ In this case, it has been suggested⁵⁹⁵ that initiation takes place by formation of a radical, such as **29**.

This is an SET mechanism (see p. 444). The photostimulated reaction has also been used for ring closure.⁵⁹⁶ In certain instances of the intermolecular reaction there is evidence that the leaving group exerts an influence on the product ratios, even when it has already departed at the time that product selection takes place.⁵⁹⁷

Alkoxy carbonyl-de-halogenation, and so on

Carbonylation of aryl bromides and iodides with carbon monoxide, an alcohol, a base, and a palladium catalyst, give carboxylic esters. Even very sterically hindered alkoxides can be used to produce the corresponding ester.⁵⁹⁹ The use of H₂O, RNH₂, or an alkali metal or calcium carboxylate⁶⁰⁰ instead of ROH, gives the carboxylic acid,⁶⁰¹ amide,⁶⁰² or mixed anhydride, respectively.⁶⁰³ Heating an aryl iodide, CO in ethanol and DBU, with a palladium catalyst, gave the ethyl ester of the aryl carboxylic acid.⁶⁰⁴ A similar result was obtained when an aryl iodide was heated in ethanol with triethylamine, CO and Pd/C.⁶⁰⁵ Ester formation via carbonylation was done in supercritical CO₂ (see p. 414).⁶⁰⁶ With certain palladium catalysts, aryl chlorides⁶⁰⁷ and aryl triflates⁶⁰⁸ can also be substrates. Aryl carboxylic acids were also prepared from aryl iodides by heating in DMF with lithium formate, LiCl, acetic anhydride and a palladium catalyst.⁶⁰⁹ A silica-supported palladium reagent has been used to convert iodobenzene to butyl benzoate, in the presence of CO and butanol.⁶¹⁰ 2-Chloropyridine was converted the butyl pyridine 2-carboxylate with this procedure.⁶¹¹ Halogenated biaryls can be converted to the tricyclic ketone, 9-fluorenone, by an intramolecular carbonylation reaction with CO and a palladium catalyst.⁶¹² A surrogate reagent used instead of CO is dicobalt octacarbonyl CO₂(CO)₈.⁶¹³ Aryl chlorides have been converted to carboxylic acids by an electrochemical synthesis,⁶¹⁴ and aryl iodides to aldehydes by treatment with

and palladium and copper catalysts, gave the alkynyl ketone $\text{RC}\equiv\text{C}(\text{C}=\text{O})\text{Ar}$.⁶²⁹

Note that seleno esters (ArCOSeAr) were prepared from aryl iodides, CO, PhSeSnBu_3 , and a palladium catalyst.⁶³⁰

13-16 Arylation of Silanes

Silyl and Silyloxy-de-halogenation, and so on

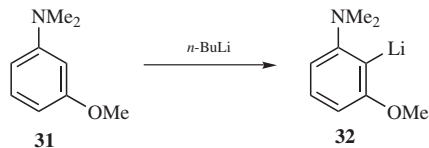

In the presence of transition-metal catalysts, such as palladium, trialkoxysilanes [$\text{HSi}(\text{OR})_3$] react with aryl halides to give the corresponding arylsilane.⁶³¹ This transformation is an alternative to the Suzuki coupling (13-10).⁶³² A similar reaction was reported using a rhodium catalyst.⁶³³ Arylsilanes can be coupled to aryl iodides in aqueous media.⁶³⁴ Arylsilanes react with alkyl halides to give the corresponding arene, in the presence of a palladium catalyst.⁶³⁵ Suzuki-type coupling using $\text{Me}_3\text{SiSiMe}_3$ leads to aryl silanes.⁶³⁶

An alternative approach reacts aryllithium reagents with siloxanes [$\text{Si}(\text{OR})_4$], to give the aryl derivative $\text{ArSi}(\text{OR})_3$.⁶³⁷

The alkylation of aromatic rings was introduced, in part, in section 10-57. The reaction of an aromatic ring with an organolithium reagent can give H–Li exchange to form an aryllithium. This reaction tends to be slow in the absence of diamine additives or if there are activating substituents on the aryl halide.⁶³⁹ When heteroatom substituents are present as in **31**, however, the reaction is facile and the lithium goes into the 2 position (as in **32**).⁶⁴⁰ This regioselectivity can be quite valuable synthetically, and is now known as *directed ortho metalation*⁶⁴¹ (see 10-57). Lithiation reactions do not necessarily rely on a complex-induced proximity effect.⁶⁴² With TMEDA/*n*-butyllithium-mediate arene lithiation reactions, the viability of directive effects (complex-induced proximate effects) has been questioned,⁶⁴³ although it is not clear if this extends to other systems (particularly when there is a strong coordinating group, such as carbamate).⁶⁴⁴ The 2 position is much more acidic than the 3 position (see Table 8.1), but a negative charge at C-3 is in a more favorable position to be stabilized by the Li⁺. Formation of the ortho arylmagnesium compound has been accomplished with bases of the form (R₂N)₂Mg.⁶⁴⁵ Note that H–Li exchange can be faster than Cl–Li exchange. Treatment of 2-chloro-5-phenylpyridine with *tert*-butyllithium leads to lithiation on the phenyl ring rather than Li–Cl exchange, and subsequent treatment with dimethyl sulfate gave 2-chloro-5-(2-methylphenyl)pyridine.⁶⁴⁶ Heteroaromatic rings do react, however. The reaction of 2-chloropyridine with 3 equivalents of butyllithium-Me₂NCH₂CH₂OLi and then iodomethane gave 2-chloro-6-methylpyridine.⁶⁴⁷ The reaction of *N*-triisopropylsilyl indole with *tert*-butyllithium and then iodomethane gave the 3-methyl derivative.⁶⁴⁸ Furfural (furan 2-carboxaldehyde) reacts with aryl iodides in the presence of a palladium catalyst to give the 5-arylfuran 2-carboxaldehyde.⁶⁴⁹

Benzene, naphthalene, and phenanthrene have been alkylated with alkyllithium reagents, though the usual reaction with these reagents is 12-22,⁶⁵⁰ and Grignard reagents have been used to alkylate naphthalene.⁶⁵¹ The addition–elimination

mechanism apparently applies in these cases too. A protected form of benzaldehyde (protected as the benzyl imine) has been similarly alkylated at the *ortho*-position with butyllithium.⁶⁵²

The alkylation of heterocyclic nitrogen compounds⁶⁵³ with alkyl lithium reagents is called *Ziegler alkylation*. Aryllithium reagents give arylation. The reaction occurs by an addition–elimination mechanism and the adduct can be isolated.⁶⁵⁴ Upon heating of the adduct, elimination of LiH occurs and an alkylated product is obtained. With respect to the 2-carbon the first step is the same as that of the S_NAr mechanism. The difference is that the unshared pair of electrons on the nitrogen combines with the lithium, so the extra pair of ring electrons has a place to go: it becomes the new unshared pair on the nitrogen. Heteroaromatic compounds can be alkylated. Pyrrole, for example, reacts with an allylic halide and zinc to give primarily the 3-substituted pyrrole.⁶⁵⁵

Mercuration of aromatic compounds⁶⁵⁶ can be accomplished with mercuric salts, most often $Hg(OAc)_2$ ⁶⁵⁷ to give $ArHgOAc$. This is ordinary electrophilic aromatic substitution and takes place by the arenium ion mechanism (p. 657).⁶⁵⁸ Aromatic compounds can also be converted to arylthallium bis(trifluoroacetates) $ArTl(OOCCF_3)_2$ by treatment with thallium(III) trifluoroacetate⁶⁵⁹ in trifluoroacetic acid.⁶⁶⁰ These arylthallium compounds can be converted to phenols, aryl iodides or fluorides (**12-31**), aryl cyanides (**12-34**), aryl nitro compounds,⁶⁶¹ or aryl esters

(12-33). The mechanism of thallation appears to be complex, with electrophilic and electron-transfer mechanisms both taking place.⁶⁶² Transient metalated aryl complexes can be formed that react with another aromatic compound. Aryl iodides reacted with benzene to form a biaryl in the presence of an iridium catalyst.⁶⁶³ Aniline derivatives reacted with TiCl_4 to give the para-homo coupling product ($\text{R}_2\text{N}-\text{Ar}-\text{Ar}-\text{NR}_2$).⁶⁶⁴

Aromatic nitro compounds can be methylated with dimethyloxosulfonium methylid⁶⁶⁵ or the methylsulfinyl carbanion (obtained by treatment of DMSO with a strong base):⁶⁶⁶

The latter reagent also methylates certain heterocyclic compounds (e.g., quinoline) and certain fused aromatic compounds (e.g., anthracene, phenanthrene).^{666,667} The reactions with the sulfur carbanions are especially useful, since none of these substrates can be methylated by the Friedel–Crafts procedure (11-10). It has been reported⁶⁶⁸ that aromatic nitro compounds can also be alkylated, not only with methyl but with other alkyl and substituted alkyl groups as well, in ortho and para positions, by treatment with an alkyl lithium compound (or, with lower yields, a Grignard reagent), followed by an oxidizing agent, such as Br_2 or DDQ (p. 1710).

A different kind of alkylation of nitro compounds uses carbanion nucleophiles that have a chlorine at the carbanionic carbon. The following process takes place:⁶⁶⁹

⁶⁶⁸Kienzle, F. *Helv. Chim. Acta* **1978**, *61*, 449.

⁶⁶⁹In some cases, the intermediate bearing the CHCl(Z) unit has been isolated: Stahly, G.P.; Stahly, B.C.; Maloney, J.R. *J. Org. Chem.* **1988**, *53*, 690.

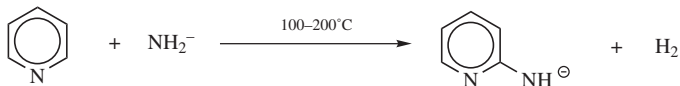

This type of process is called *vicarious nucleophilic substitution of hydrogen*.⁶⁷⁰ The Z group is electron -withdrawing (e.g., SO₂R, SO₂OR, SO₂NR₂, COOR, or CN); it stabilizes the negative charge. The carbanion attacks the activated ring ortho or para to the nitro group.⁶⁷¹ Hydride ion H⁻ is not normally a leaving group, but in this case the presence of the adjacent Cl allows the hydrogen to be replaced. Hence, Cl is a “vicarious” leaving group. Other leaving groups have been used (e.g., OMe, SPh), but Cl is generally the best. Many groups W in ortho, meta, or para positions do not interfere. The reaction is also successful for di- and trinitro compounds, for nitronaphthalenes,⁶⁷² and for many nitro heterocycles. Z⁻CR-Cl may also be used.⁶⁷³ When Br₃C⁻ or Cl₃C⁻ is the nucleophile the product is ArCHX₂, which can easily be hydrolyzed to ArCHO.⁶⁷⁴ This is therefore an indirect way of formylating an aromatic ring containing one or more NO₂ groups, which cannot be done by any of the formylations mentioned in Chapter 11 (11-1–11-18).

Replacement of an amino group is possible. When aniline derivatives were treated with allyl bromide and *tert*-butyl nitrite (*t*-BuONO), the aryl-allyl coupling product was formed (Ar-NH₂ → Ar-CH₂CH=CH₂).⁶⁷⁵

For the introduction of CH₂SR groups into phenols, see 11-23. See also 14-19. OS II, 517.

13-18 Amination of Nitrogen Heterocycles

Amination or Amino-de-hydrogenation

Pyridine and other heterocyclic nitrogen compounds can be aminated with alkali-metal amides in a process called the *Chichibabin reaction*.⁶⁷⁶ The attack is always in the 2 position unless both such positions are filled, in which case the 4 position is attacked. Substituted alkali-metal amides (e.g., RNH⁻ and R₂N⁻) have also been used. The mechanism is probably similar to that of 13-17. The existence of intermediate ions, such as 33

33

(from quinoline) has been demonstrated by NMR spectra.⁶⁷⁷ A pyridyne type of intermediate was ruled out by several observations including the facts that 3-ethylpyridine gave 2-amino-3-ethylpyridine⁶⁷⁸ and that certain heterocycles that cannot form an aryne could nevertheless be successfully aminated. Nitro compounds do not give this reaction,⁶⁷⁹ but they have been aminated ($\text{ArH} \rightarrow \text{ArNH}_2$ or ArNHR) via the vicarious substitution principle (see **13-17**), using 4-amino- or 4-alkylamino-1,2,4-triazoles as nucleophiles.⁶⁸⁰ The vicarious leaving group in this case is the triazole ring. Note, however, that 3-nitropyridine was converted to 6-amino-3-nitropyridine by reaction with KOH, hydroxylamine and ZnCl_2 .⁶⁸¹

Analogous reactions have been carried out with hydrazide ions, R_2NNH^- .⁶⁸² A mixture of NO_2 and O_3 , with excess NaHSO_3 , converted pyridine to 3-aminopyridine.⁶⁸³ For other methods of aminating aromatic rings, see **11-6**.

There are no *Organic Syntheses* references, but see OS **V**, 977, for a related reaction.

NITROGEN AS LEAVING GROUP

The diazonium group can be replaced by a number of groups.⁶⁸⁴ Some of these are nucleophilic substitutions, with $\text{S}_{\text{N}}1$ mechanisms (p. 432), but others are free-radical reactions and are treated in Chapter 14. The solvent in all these reactions is usually water. With other solvents it has been shown that the $\text{S}_{\text{N}}1$ mechanism is favored by solvents of low nucleophilicity, while those of high nucleophilicity favor free-radical mechanisms.⁶⁸⁵ The N_2^+ group⁶⁸⁶ can be replaced by Cl^- , Br^- , and CN^- , by a nucleophilic mechanism (see OS **IV**, 182), but the Sandmeyer reaction is much more useful (**14-20**). Transition metal catalyzed reactions are known involving aryl-diazonium salts, and diazonium variants of the Heck reaction (**13-10**) and Suzuki coupling (**13-12**) were discussed previously. As mentioned on p. 866 it must be

kept in mind that the N_2^+ group can activate the removal of another group on the ring. In a few cases, nitrogen groups, such as nitro or ammonium can be replaced.

13-19 Diazotization

When primary aromatic amines are treated with nitrous acid, diazonium salts are formed.⁶⁸⁷ The reaction also occurs with aliphatic primary amines, but aliphatic diazonium ions are extremely unstable, even in solution (see p. 500). Aromatic diazonium ions are more stable, because of the resonance interaction between the nitrogens and the ring:

Incidentally, **34** contributes more to the hybrid than **35**, as shown by bond-distance measurements.⁶⁸⁸ In benzenediazonium chloride, the C–N distance is $\sim 1.42 \text{ \AA}$, and the N–N distance $\sim 1.08 \text{ \AA}$,⁶⁸⁹ which values fit more closely to a single and a triple bond than to two double bonds (see Table 1.5). Even aromatic diazonium salts are stable only at low temperatures, usually only $< 5^\circ\text{C}$, although more stable ones, such as the diazonium salt obtained from sulfanilic acid, are stable up to 10 or 15°C . Diazonium salts are usually prepared in aqueous solution and used without isolation,⁶⁹⁰ although it is possible to prepare solid diazonium salts if desired (see **13-23**). The stability of aryl diazonium salts can be increased by crown ether complexion.⁶⁹¹

For aromatic amines, the reaction is very general. Halogen, nitro, alkyl, aldehyde, sulfonic acid, and so on, groups do not interfere. Since aliphatic amines do not react with

Macrocyclic Chem.* **1981**, *2*, 1.

nitrous acid below a pH ~ 3 , it is even possible, by working at a pH ~ 1 , to diazotize an aromatic amine without disturbing an aliphatic amino group in the same molecule.⁶⁹²

If an aliphatic amino group is attached to a COOR, CN, CHO, COR, and so on, and has not a hydrogen, treatment with nitrous acid gives not a diazonium salt, but a diazo compound.⁶⁹³ Such diazo compounds can also be prepared, often more conveniently, by treatment of the substrate with isoamyl nitrite and a small amount of acid.⁶⁹⁴ Certain heterocyclic amines also give diazo compounds rather than diazonium salts.⁶⁹⁵

Despite the fact that diazotization takes place in acid solution, the actual species attacked is not the salt of the amine, but the small amount of free amine present.⁶⁹⁶ It is because aliphatic amines are stronger bases than aromatic ones that at pH values < 3 there is not enough free amine present for the former to be diazotized, while the latter still undergo the reaction. In dilute acid the actual attacking species is N_2O_3 , which acts as a carrier of NO^+ . Evidence is that the reaction is second order in nitrous acid and, at sufficiently low acidities, the amine does not appear in the rate expression.⁶⁹⁷ Under these conditions the mechanism is

There exists other evidence for this mechanism.⁶⁹⁸ Other attacking species can be NOCl, H₂NO₂⁺, and at high acidities even NO⁺. Nucleophiles (e.g., Cl⁻, SCN⁻, thiourea) catalyze the reaction by converting the HONO to a better electrophile (e.g., HNO₂ + Cl⁻ + H⁺ → NOCl + H₂O).⁶⁹⁹

N-Aryl ureas are converted to the aryldiazonium nitrate upon treatment with NaNO₂ and H₂SO₄ in dioxane⁷⁰⁰ or with DMF–NO₂ in DMF.⁷⁰¹

There are many preparations of diazonium salts listed in *Organic Syntheses*, but they are always prepared for use in other reactions. We do not list them here, but under reactions in which they are used. The preparation of aliphatic diazo compounds can be found in OS **III**, 392; **IV**, 424. See also, OS **VI**, 840.

13-20 Hydroxylation of Aryldiazonium Salts

Hydroxy-de-diazonation

This reaction is formally analogous to **13-1**, but with a N₂⁺ leaving group rather than a halide. Water is usually present whenever diazonium salts are made, but at these temperatures (0–5°C) the reaction proceeds very slowly. When it is *desired* to have OH replace the diazonium group, the excess nitrous acid is destroyed and the solution is usually boiled. Some diazonium salts require even more vigorous treatment, for example, boiling with aqueous sulfuric acid or with trifluoroacetic acid containing potassium trifluoroacetate.⁷⁰² The reaction can be performed on solutions of any diazonium salts, but hydrogen sulfates are preferred to chlorides or nitrates, since in these cases there is competition from the nucleophiles Cl⁻ or NO₃⁻. A better method, which is faster, avoids side reactions, takes place at room temperature, and gives higher yields consists of adding Cu₂O to a dilute solution of the diazonium salt dissolved in a solution containing a large excess of Cu(NO₃)₂.⁷⁰³ Aryl radicals are intermediates when this method is used. It has been shown that aryl radicals are at least partly involved when ordinary hydroxy-de-diazonation is carried out in weakly alkaline aqueous solution.⁷⁰⁴ Decomposition of arenediazonium tetrafluoroborates in F₃CSO₂OH gives aryl triflates directly, in high yields.⁷⁰⁵

13-21 Replacement by Sulfur-Containing Groups

Mercapto-de-diazoniation, and so on

These reactions are convenient methods for incorporating a sulfur-containing group onto an aromatic ring. With $\text{Ar}'\text{S}^-$, diazosulfides $\text{Ar}-\text{N}=\text{N}-\text{S}-\text{Ar}'$ are intermediates,⁷⁰⁶ which can in some cases be isolated.⁷⁰⁷ Thiophenols can be made as shown above, but more often the diazonium ion is treated with $\text{EtO}-\text{CSS}^-$ or S_2^{2-} , which give the expected products, and these are easily convertible to thiophenols. Aryldiazonium salts are prepared by the reaction of an aniline derivative with an alkyl nitrite (RONO), and when formed in the presence of dimethyl disulfide (MeS-SMe), the product is the thioether, $\text{Ar}-\text{S}-\text{Me}$.⁷⁰⁸ Aryl triflates have been converted to the aryl thiol using NaST(P5) and a palladium catalyst, followed by treatment with tetrabutylammonium fluoride⁷⁰⁹ (see also, 14-22).

OS II, 580; III, 809 (but see OS V, 1050). Also see, OS II, 238.

13-22 Replacement by Iodine

Iodo-de-diazoniation

One of the best methods for the introduction of iodine into aromatic rings (see 13-7) is the reaction of diazonium salts with iodide ions. Analogous reactions with chloride, bromide, and fluoride ions give poorer results, and 14-20 and 13-23 are preferred for the preparation of aryl chlorides, bromides, and fluorides. However, when other diazonium reactions are carried out in the presence of these ions, halides are usually side products. Aniline has also been converted to fluorobenzene by treatment with *t*-BuONO and SiF_4 followed by heating.⁷¹⁰ A related reaction between $\text{PhN}=\text{N}-\text{NC}_4\text{H}_8$ and iodine gave iodobenzene.⁷¹¹

The actual attacking species is probably not only I^- if it is I^- at all. The iodide ion is oxidized (by the diazonium ion, nitrous acid, or some other oxidizing agent)

⁷⁰⁶Abeywickrema, A.N.; Beckwith, A.L.J. *J. Am. Chem. Soc.* **1986**, *108*, 8227, and references cited therein.

to iodine, which in a solution containing iodide ions is converted to I_3^- ; this is the actual attacking species, at least partly. This was shown by isolation of $ArN_2^+ I_3^-$ salts, which, on standing, gave ArI .⁷¹² From this, it can be inferred that the reason the other halide ions give poor results is not that they are poor nucleophiles but that they are poor reducing agents (compared with iodide). There is also evidence for a free-radical mechanism.⁷¹³

The hydroxyl group of a phenol can be replaced with iodine. The reaction of phenol with a boronic ester and a palladium catalyst, followed by reaction with NaI and chloramine-T converts phenol to iodobenzene.⁷¹⁴

OS II, 351, 355, 604; V, 1120.

13-23 The Schiemann Reaction

Fluoro-de-diazonation (overall transformation)

Heating of diazonium fluoroborates (the *Schiemann* or *Balz-Schiemann reaction*) is by far the best way of introducing fluorine into an aromatic ring.⁷¹⁵ In the most common procedure, the fluoroborate salts are prepared by diazotizing as usual with nitrous acid and HCl and then adding a cold aqueous solution of $NaBF_4$, HBF_4 , or NH_4BF_4 . A precipitate forms, which is dried, and the salt is heated in the dry state. These salts are unusually stable for diazonium salts, and the reaction is usually successful. In general, any aromatic amine that can be diazotized will form a BF_4^- salt, usually with high yields. The diazonium fluoroborates can be formed directly from primary aromatic amines with *tert*-butyl nitrite and BF_3 -etherate.⁷¹⁶ The reaction has also been carried out on $ArN_2^+ PF_6^-$, $ArN_2^+ SbF_6^-$, and $ArN_2^+ AsF_6^-$ salts, in many cases with better yields.⁷¹⁷ Aryl chlorides and bromides are more commonly prepared by the Sandmeyer reaction (14-20). In an alternative procedure, aryl fluorides have been prepared by treatment of aryltriazenes $Ar-N=N-NR_2$ with 70% HF in pyridine.⁷¹⁸

The mechanism is of the S_N1 type. That aryl cations are intermediates was shown by the following experiments:⁷¹⁹ Aryl diazonium chlorides are known to

⁷¹⁹See also, Swain, C.G.; Sheats, J.E.; Harbison, K.G. *J. Am. Chem. Soc.* **1975**, 97, 783, 796; Becker, H.G.O.; Israel, G. *J. Prakt. Chem.* **1979**, 321, 579.

arylate other aromatic rings by a free-radical mechanism (see **13-27**). In radical arylation it does not matter whether the other ring contains electron-withdrawing or electron-donating groups; in either case a mixture of isomers is obtained, since the attack is not by a charged species. If an aryl radical were an intermediate in the Schiemann reaction and the reaction were run in the presence of other rings, it should not matter what kinds of groups were on these other rings: Mixtures of biaryls should be obtained in all cases. But if an aryl cation is an intermediate in the Schiemann reaction, compounds containing meta-directing groups, that is, meta directing for *electrophilic* substitutions, should be meta-arylated and those containing ortho-para-directing groups should be ortho- and para aryated, since an aryl cation should behave in this respect like any electrophile (see Chapter 11). Experiments have shown⁷²⁰ that such orientation is observed, demonstrating that the Schiemann reaction has a positively charged intermediate. The attacking species, in at least some instances, is not F^- but BF_4^- .⁷²¹

OS II, 188, 295, 299; V, 133.

13-24 Conversion of Amines to Azo Compounds

N-Arylimino-de-dihydro-bisubstitution

Aromatic nitroso compounds combine with primary arylamines in glacial acetic acid to give symmetrical or unsymmetrical azo compounds (the *Mills reaction*).⁷²² A wide variety of substituents may be present in both aryl groups. Unsymmetrical azo compounds have also been prepared by the reaction between aromatic nitro compounds ArNO_2 and *N*-acyl aromatic amines $\text{Ar}'\text{NHAc}$.⁷²³ The use of phase-transfer catalysis increased the yields.

13-25 Methylation, Vinylation, and Arylation of Diazonium Salts

Methyl-de-diazoniatio, and so on

A methyl group can be introduced into an aromatic ring by treatment of diazonium salts with tetramethyltin and a palladium acetate catalyst.⁷²⁴ The reaction has been performed with Me, Cl, Br, and NO_2 groups on the ring. A vinylic group can

⁷²⁰Makarova, L.G.; Matveeva, M.K. *Bull. Acad. Sci. USSR Div. Chem. Sci.* **1958**, 548; Makarova, L.G.; Matveeva, M.K.; Gribchenko, E.A. *Bull. Acad. Sci. USSR Div. Chem. Sci.* **1958**, 1399.

be introduced with $\text{CH}_2=\text{CHSnBu}_3$. When an aryl amine is treated with *tert*-butyl hyponitrite (*t*-BuONO) and allyl bromide, the nitrogen is displaced to give allyl-aryl compound.⁷²⁵

Aryl diazonium salts can be used coupled with alkenes in a Heck-like reaction (12-15).⁷²⁶ Other reactive aryl species also couple with aryldiazonium salts in the presence of a palladium catalyst.⁷²⁷ A Suzuki type coupling (13-9) has also been reported using arylboronic acids, aryldiazonium salts and a palladium catalyst.⁷²⁸

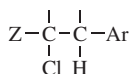

Aryltrifluoroborates (12-28) react with aryldiazonium salts in the presence of a palladium catalyst to give the corresponding biaryl.⁷²⁹ Arylborate esters also react using a palladium catalyst, and the aryl diazonium unit reacts faster than an aryl halide.⁷³⁰

13-26 Arylation of Activated Alkenes by Diazonium Salts: Meerwein Arylation

Arylation or Aryl-de-hydrogenation

Alkenes activated by an electron-withdrawing group (Z may be C=C, halogen, C=O, Ar, CN, etc.) can be arylated by treatment with a diazonium salt and a cupric chloride⁷³¹ catalyst. This is called the *Meerwein*

arylation reaction.⁷³² Addition of ArCl to the double bond (to give) is a side reaction (15-46). In an improved procedure, an arylamine is treated with an alkyl nitrite (generating ArN_2^+ *in situ*) and a copper(II) halide in the presence of the alkene.⁷³³

The mechanism is probably of the free-radical type, with AR^\bullet (36) forming as in 14-20, and then halogen transfer to give 37 or elimination to give 38.⁷³⁴

The radical **36** can react with cupric chloride by two pathways, one of which leads to addition and the other to substitution. Even when the addition pathway is taken, however, the substitution product may still be formed by subsequent elimination of HCl. Note that radical reactions are presented in Chapter 14, but the coupling of an alkene with an aromatic compound containing a leaving group prompted its placement here. Note also the similarity to the Heck reaction in **13-10**.

A variation of this reaction uses a palladium–copper catalyst on Montmorillonite clay. When aniline reacted with methyl acrylate in acetic acid and the Pd–Cu–Montmorillonite K10, PhCH=CHCO₂Me was obtained.⁷³⁵

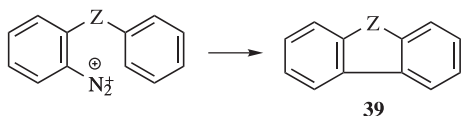

OS IV, 15.

13-27 Arylation of Aromatic Compounds by Diazonium Salts

Arylation or Aryl-de-hydrogenation

When the normally acidic solution of a diazonium salt is made alkaline, the aryl portion of the diazonium salt can couple with another aromatic ring. Known as the *Gomberg* or *Gomberg–Bachmann reaction*,⁷³⁶ it has been performed on several types of aromatic rings and on quinones. Yields are not high (usually <40%) because of the many side reactions undergone by diazonium salts, though higher yields have been obtained under phase-transfer conditions.⁷³⁷ The conditions of the Meerwein reaction (**13-26**), treatment of the solution with a copper-ion catalyst, have also been used, as has the addition of sodium nitrite in Me₂SO (to benzene diazonium fluoroborate in DMSO).⁷³⁸

⁷³⁷Beadle, J.R.; Korzeniowski, S.H.; Rosenberg, D.E.; Garcia-Slanga, B.J.; Gokel, G.W. *J. Org. Chem.* **1984**, *49*, 1594.

⁷³⁸Kamigata, N.; Kurihara, T.; Minato, H.; Kobayashi, M. *Bull. Chem. Soc. Jpn.* **1971**, *44*, 3152.

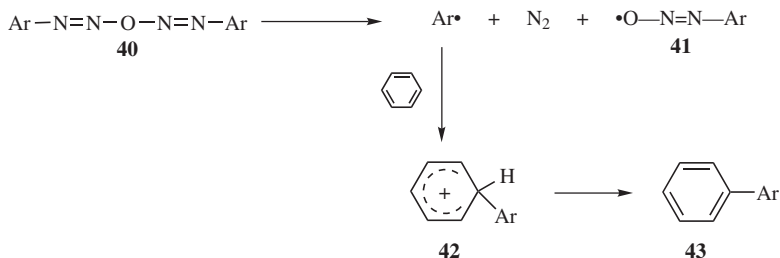

When the Gomberg–Bachmann reaction is performed intramolecularly as in the formation of **39**, either by the alkaline solution or by the copper-ion procedure, it is called the *Pschorr ring closure*⁷³⁹ and yields are usually somewhat higher. Still higher yields have been obtained by carrying out the Pschorr reaction electrochemically.⁷⁴⁰ The Pschorr reaction has been carried out for $Z = \text{CH}=\text{CH}$, CH_2CH_2 , NH , $\text{C}=\text{O}$, CH_2 , and quite a few others. A rapid and convenient way to carry out the Pschorr synthesis is to diazotize the amine substrate with isopropyl nitrite in the presence of sodium iodide, in which case the ring-closed product is formed in one step.⁷⁴¹

Other compounds with nitrogen–nitrogen bonds have been used instead of diazonium salts. Among these are *N*-nitroso amides $[\text{ArN}(\text{NO})\text{COR}]$, triazenes,⁷⁴² and azo compounds. Still another method involves treatment of an aromatic primary amine directly with an alkyl nitrite in an aromatic substrate as solvent.⁷⁴³

In each case, the mechanism involves generation of an aryl radical from a covalent azo compound. In acid solution, diazonium salts are ionic and their reactions are polar. When they cleave, the product is an aryl cation (see p. 856). However, in neutral or basic solution, diazonium ions are converted to covalent compounds, and these cleave to give free radicals (Ar^\bullet and Z^\bullet). Note that radical reactions are presented in Chapter 14, but the coupling of an aromatic ring with an aromatic compound containing a leaving group prompted its placement here. Note the similarity to the Suzuki reaction in **13-12**.

Under Gomberg–Bachmann conditions, the species that cleaves is the anhydride, **40**.⁷⁴⁴

⁷³⁹For a review, see Abramovitch, R.A. *Adv. Free-Radical Chem.* **1966**, 2, 87.

⁷⁴²See, for example, Patrick, T.B.; Willaredt, R.P.; DeGonia, D.J. *J. Org. Chem.* **1985**, 50, 2232; Butler, R.N.; O'Shea, P.D.; Shelly, D.P. *J. Chem. Soc. Perkin Trans. 1*, **1987**, 1039.

⁷⁴³Cadogan, J.I.G. *J. Chem. Soc.* **1962**, 4257; Fillipi, G.; Vernin, G.; Dou, H.J.; Metzger, J.; Perkins, M.J. *Bull. Soc. Chim. Fr.* **1974**, 1075.

⁷⁴⁴Rüchardt, C.; Merz, E. *Tetrahedron Lett.* **1964**, 2431; Eliel, E.L.; Saha, J.G.; Meyerson, S. *J. Org. Chem.* **1965**, 30, 2451.

The aryl radical thus formed attacks the substrate to give the intermediate **42** (see p. 940), from which the radical **41** abstracts hydrogen to give the product, **43**. *N*-Nitroso amides probably rearrange to *N*-acyloxy compounds (**44**), which cleave to give aryl radicals.⁷⁴⁵ There is evidence that the reaction with alkyl nitrites also involves attack by aryl radicals.⁷⁴⁶

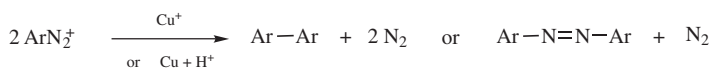

The Pschorr reaction can take place by two different mechanisms, depending on conditions: (1) attack by an aryl radical (as in the Gomberg–Bachmann reaction) or (2) attack by an aryl cation (similar to the S_N1 mechanism discussed on p. 857).⁷⁴⁷ Under certain conditions the ordinary Gomberg–Bachmann reaction can also involve attack by aryl cations.⁷⁴⁸

OS I, 113; IV, 718.

13-28 Aryl Dimerization With Diazonium Salts

De-diazonio-coupling; Arylazo-de-diazonio-substitution

When diazonium salts are treated with cuprous ion (or with copper and acid, in which case it is called the *Gatterman method*), two products are possible. If the ring contains electron-withdrawing groups, the main product is the biaryl, but the presence of electron-donating groups leads mainly to the azo compound. This reaction is different from **13-27** (and from **19-14**) in that *both* aryl groups in the product originate from ArN₂⁺, that is, hydrogen is not a leaving group in this reaction. The mechanism probably involves free radicals.⁷⁴⁹

13-29 Replacement of Nitro

Alkyl-de-nitration, Hydroxy and alkoxy-de-nitration, Halo-de-nitration

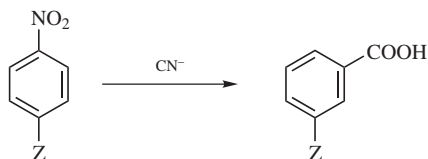

In some cases, the nitrogen group of an aromatic nitro compound can be replaced with an alkyl group. The reaction of 1,4-dinitrobenzene with potassium *tert*-butoxide in the presence of BEt_3 , for example, gave 4-ethylnitrobenzene.⁷⁵⁰

Other nucleophiles can replace a nitrogen-containing group. The reaction of hydroxide with Ar-Y , where $\text{Y} = \text{nitro},^{751} \text{azide}, \text{NR}_3^+$, and so on gives the corresponding phenol. This latter reaction works with alkoxide nucleophiles to give the corresponding aryl ether. The nitro can be replaced with chloro by use of NH_4Cl , PCl_5 , SOCl_2 , HCl , Cl_2 , or CCl_4 . Some of these reagents operate only at high temperatures and the mechanism is not always nucleophilic substitution. Activated aromatic nitro compounds can be converted to fluorides with fluoride ion.⁷⁵²

The reaction of vinyl nitro compounds ($\text{C}=\text{C}-\text{NO}_2$) and aryl iodide to give the styrene compound ($\text{C}=\text{C}-\text{Ar}$) was reported using BEt_3 and exposure to air.⁷⁵³

REARRANGEMENTS

13-30 The von Richter Rearrangement

Hydro-de-nitro-*cine*-substitution

When aromatic nitro compounds are treated with cyanide ion, the nitro group is displaced and a carboxyl group enters with *cine* substitution (p. 860), always ortho to the displaced group, never meta or para. The scope of this reaction, called the *von Richter rearrangement*, is variable.⁷⁵⁴ As with other nucleophilic aromatic substitutions, the reaction gives best results when electron-withdrawing groups are in ortho and para positions, but yields are low, usually <20% and never >50%.

⁷⁵⁴For a review, see Shine, H.J. *Aromatic Rearrangements*, Elsevier, NY, **1967**, pp. 326–335.

At one time it was believed that a nitrile, ArCN , was an intermediate, since cyanide is the reagent and nitriles are hydrolyzable to carboxylic acids under the reaction conditions (16-4). However, a remarkable series of results proved this belief to be in error. Bunnett and Rauhut demonstrated⁷⁵⁵ that α -naphthyl cyanide is *not* hydrolyzable to α -naphthoic acid under conditions at which β -nitronaphthalene undergoes the von Richter rearrangement to give α -naphthoic acid. This proved that the nitrile cannot be an intermediate. It was subsequently demonstrated that N_2 is a major product of the reaction.⁷⁵⁶ It had previously been assumed that all the nitrogen in the reaction was converted to ammonia, which would be compatible with a nitrile intermediate, since ammonia is a hydrolysis product of nitriles. At the same time it was shown that NO_2^- is not a major product. The discovery of nitrogen indicated that a nitrogen–nitrogen bond must be formed during the course of the reaction. A mechanism in accord with all the facts was proposed by Rosenblum.⁷⁵⁶

Note that **46** is a stable compound; hence it should be possible to prepare it independently and to subject it to the conditions of the von Richter rearrangement. This was done and the correct products are obtained.⁷⁵⁷ Further evidence is that when **45** ($\text{Z} = \text{Cl}$ or Br) was treated with cyanide in H_2^{18}O , half the oxygen in the product was labeled, showing that one of the oxygens of the carboxyl group came from the nitro group and one from the solvent, as required by this mechanism.⁷⁵⁸

13-31 The Sommelet–Hauser Rearrangement

Benzylic quaternary ammonium salts, when treated with alkali-metal amides, undergo a rearrangement called the *Sommelet–Hauser rearrangement*.⁷⁵⁹ Since the product is a benzylic tertiary amine, it can be further alkylated and the product again subjected to the rearrangement. This process can be continued around the ring until an ortho position is blocked.⁷⁶⁰

The rearrangement occurs with high yields and can be performed with various groups present in the ring.⁷⁶¹ The reaction is most often carried out with three methyl groups on the nitrogen, but other groups can also be used, though if a β -hydrogen is present, Hofmann elimination (**17-7**) often competes. The *Stevens rearrangement* (**18-21**) is also a competing process.⁷⁶² When both rearrangements are possible, the Stevens is favored at high temperatures and the Sommelet–Hauser at low temperatures.⁷⁶³ The mechanism is

The benzylic hydrogen is most acidic and is the one that first loses a proton to give the ylid **47**. However, **48**, which is present in smaller amount, is the species

⁷⁵⁹For reviews, see Pine, S.H. *Org. React.*, **1970**, *18*, 403; Lopley, A.R.; Giumanini, A.G. *Mech. Mol. Migr.* **1971**, *3*, 297; Wittig, G. *Bull. Soc. Chim. ⁷⁶²For a method that uses nonbasic conditions, and gives high yields of the Sommelet–Hauser product, with little or no Stevens rearrangement, see Nakano, M.; Sato, Y. *J. Org. Chem.* **1987**, *52*, 1844; Shirai, N.; Sato, Y. *J. Org. Chem.* **1988**, *53*, 194.

⁷⁶³Wittig, G.; Streib, H. *Liebigs Ann. Chem.* **1953**, 584, 1.

that undergoes the rearrangement, shifting the equilibrium in its favor. This mechanism is an example of a [2,3] sigmatropic rearrangement (see **18-35**). Another mechanism that might be proposed is one in which a methyl group actually breaks away (in some form) from the nitrogen and then attaches itself to the ring. That this is not so was shown by a product study.⁷⁶⁴ If the second mechanism were true, **49** should give **50**, but the first mechanism predicts the formation of **51**, which is what was actually obtained.⁷⁶⁵

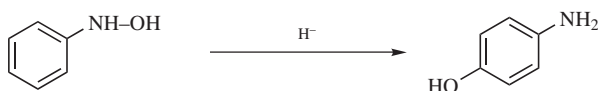

The mechanism as we have pictured it can lead only to an ortho product. However, a small amount of para product has been obtained in some cases.⁷⁶⁶ A mechanism⁷⁶⁷ in which there is a dissociation of the ArC–N bond (similar to the ion-pair mechanism of the Stevens rearrangement, p. 1622) has been invoked to explain the para products that are observed.

Sulfur ylids containing a benzylic group (analogous to **48**) undergo an analogous rearrangement.⁷⁶⁸

OS IV, 585.

13-32 Rearrangement of Aryl Hydroxylamines

1/C-Hydro-5/N-hydroxy-interchange

Aryl hydroxylamines treated with acids rearrange to aminophenols.⁷⁶⁹ Although this reaction (known as the *Bamberger rearrangement*) is similar in appearance to

⁷⁶⁴For other evidence for the mechanism given, see Hauser, C.R.; Van Eenam, D.N. *J. Am. Chem. Soc.* **1957**, *79*, 5512; Jones, F.N.; Hauser, C.R. *J. Org. ⁷⁶⁹For a review, see Shine, H.J. *Aromatic Rearrangements*, Elsevier, NY, **1967**, pp. 182–190.

11-28–11-32, the attack on the ring is not electrophilic but nucleophilic. The rearrangement is intermolecular, with the following mechanism:

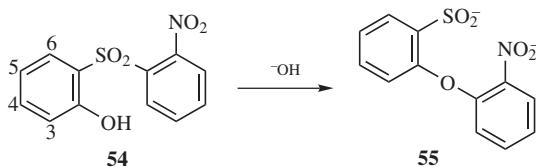

Among the evidence⁷⁷⁰ for this mechanism are the facts that other products are obtained when the reaction is run in the presence of competing nucleophiles, for example, *p*-ethoxyaniline when ethanol is present, and that when the para position is blocked, compounds similar to **53** are isolated. In the case of 2,6-dimethylphenylhydroxylamine, the intermediate nitrenium ion **52** was trapped, and its lifetime in solution was measured.⁷⁷¹ The reaction of **52** with water was found to be diffusion controlled.²⁸⁸

OS IV, 148.

13-33 The Smiles Rearrangement

The *Smiles rearrangement* actually comprises a group of rearrangements that follow the pattern given above.⁷⁷² A specific example is the reaction of **54** with hydroxide to give **55**.

Smiles rearrangements are simply intramolecular nucleophilic substitutions. In the example given, SO_2Ar is the leaving group and ArO^- the nucleophile, and the nitro group serves to activate its ortho position. Halogens also serve as activating

⁷⁷⁰For additional evidence, see Sone, T.; Hamamoto, K.; Seiji, Y.; Shinkai, S.; Manabe, O. *J. Chem. Soc. Perkin Trans. 2* **1981**, 1596; Kohnstam, G.; Petch, W.A.; Williams, D.L.H. *J. Chem. Soc. ⁷⁷¹Fishbein, J.C.; McClelland, R.A. *J. Am. Chem. Soc.* **1987**, *109*, 2824.

⁷⁷²For reviews, see Truce, W.E.; Kreider, E.M.; Brand, W.W. *Org. React.*, **1971**, *18*, 99; Shine, H.J. *Aromatic Rearrangements*, Elsevier, NY, **1967**, pp. 307–316; Stevens, T.S.; Watts, W.E. *Selected Molecular Rearrangements*, Van Nostrand-Reinhold, Princeton, NJ, **1973**, pp. 120–126.

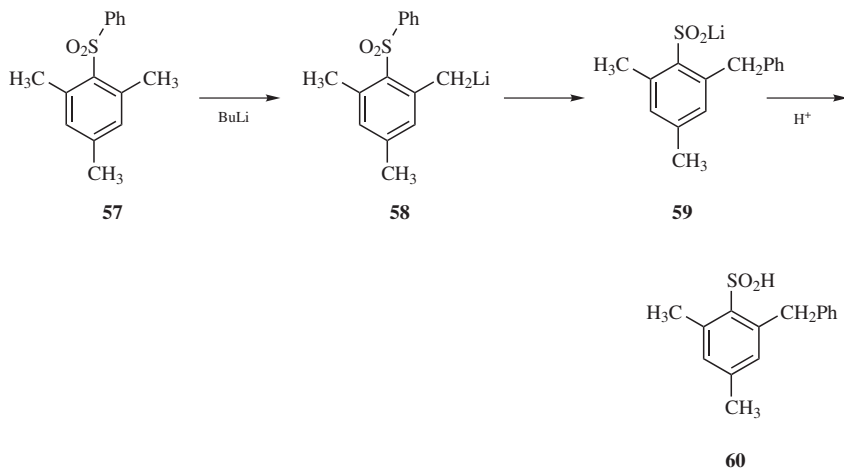

groups.⁷⁷³ The ring at which the substitution takes place is nearly always activated, usually by ortho or para nitro groups. Here X is usually S, SO, SO₂,⁷⁷⁴ O, or COO, and Y is usually the conjugate base of OH, NH₂, NHR, or SH. The reaction has even been carried out with Y = CH₂⁻ (phenyllithium was the base here).⁷⁷⁵

The reaction rate is greatly enhanced by substitution in the 6 position of the attacking ring, for steric reasons. For example, a methyl, chloro, or bromo group in the 6 position of **54** caused the rate to be $\sim 10^5$ times faster than when the same groups were in the 4 position,⁷⁷⁶ though electrical effects should be similar at these positions. The enhanced rate comes about because the most favorable conformation the molecule can adopt to suit the bulk of the 6-substituent is also the conformation required for the rearrangement. Thus, less entropy of activation is required.

Although the Smiles rearrangement is usually carried out on compounds containing two rings, this need not be the case, as in the formation of **56**.⁷⁷⁷

In this case, the sulfenic acid (**56**) is unstable⁷⁷⁸ and the actual products isolated were the corresponding sulfinic acid (RSO₂H) and disulfide (R₂S₂).

⁷⁷⁸For a stable sulfenic acid, see Nakamura, N. *J. Am. Chem. Soc.* **1983**, *105*, 7172.

In the Smiles rearrangement, the nucleophile Y is most often the conjugate base of SH, SO₂NHR, SO₂NH₂, NH₂, NHR, OH, OR. There are few examples where Y is a carbanion, and the most common example is probably the *Truce–Smiles rearrangement*, where L–YH is an *o*-tolyl group.⁷⁷⁹ The prototypical Truce–Smiles rearrangement requires use of a strong base to form the benzylic carbanion that undergoes the rearrangement. When sulfone **57** was treated with butyllithium, for example, deprotonation led to the benzylic lithium compound **58**. Truce–Smiles rearrangement led to **59**, and hydrolysis gave the sulfinic acid, **60**.⁷⁷⁹ Truce–Smiles rearrangements with stabilized benzylic carbanions are known,⁷⁸⁰ and rearrangements of carbanions in general fall under this category.⁷⁸¹ Relatively few examples have been reported, however.⁷⁸² Truce–Smiles rearrangements of sulfones that proceed through a six-membered transition state have been reported.⁷⁸³ In another example, displacement of an activated aryl fluoride with *o*-hydroxyacetophenone gave a product that was *C*-arylated adjacent to the ketone.⁷⁸⁴

Substitution Reactions: Free Radicals

MECHANISMS

Free-Radical Mechanisms in General¹

A free-radical process consists of at least two steps. The first step involves the *formation* of free radicals, usually by homolytic cleavage of bond, that is, a cleavage in which each fragment retains one electron:

This is called an *initiation* step. It may happen spontaneously or may be induced by heat² or light (see the discussion on p. 279), depending on the type of bond.³ Peroxides, including hydrogen peroxide, dialkyl, diacyl, and alkyl acyl peroxides, and peroxyacids are the most common source of free radicals induced spontaneously or by heat, but other organic compounds with low-energy bonds, such as azo compounds, are also used. Molecules that are cleaved by light are most often chlorine, bromine, and various ketones (see Chapter 7). Radicals can also be formed

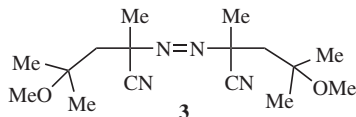

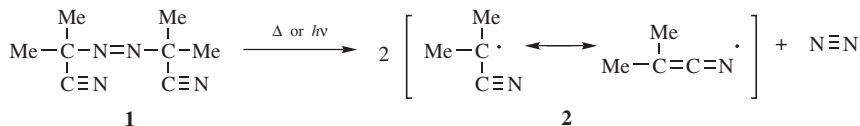

¹For books on free-radical mechanisms, see Nonhebel, D.C.; Tedder, J.M.; Walton, J.C. *Radicals*, Cambridge University Press, Cambridge, **1979**; Nonhebel, D.C.; Walton, J.C. *Free-Radical Chemistry*, Cambridge University Press, London, **1974**; Huyser, E.S. *Free-Radical Chain Reactions*, Wiley, NY, **1970**; Pryor, W.A. *Free Radicals*, McGraw-Hill, NY, **1966**; For reviews, see Huyser, E.S., in McManus, S.P. *Organic Reactive Intermediates*, Academic Press, NY, **1973**, pp. 1–59. in another way, by a one-electron transfer (loss or gain), for example, $A^+ + e^- \rightarrow A^\bullet$. One-electron transfers usually involve inorganic ions or electrochemical processes.

Dialkyl peroxides (ROOR) or alkyl hydroperoxides (ROOH) decompose to hydroxy radicals (HO•) or alkoxy radicals (RO•) when heated.⁴ Cumene hydroperoxide (PhCMe₂OOH), bi-*tert*-butylperoxide (Me₃COOCMe₃),⁵ and benzoyl peroxide [(PhCO)O₂] undergo homolytic cleavage at temperatures compatible with many organic reactions, allowing some control of the reaction, and they are reasonably soluble in organic solvents. In general, when a peroxide decomposes, the oxygen radical remains in a “cage” for $\sim 10^{-11}$ s before diffusing away. The radical can recombine (dimerize), or react with other molecules. Azo compounds, characterized by a $-N=N-$ bond, are free-radical precursors that liberate nitrogen gas (N₂) upon decomposition. azobis(isobutyronitrile) (AIBN, **1**) is a well-known example, which decomposes to give nitrogen and the cyano stabilized radical, **2**.⁶ Homolytic dissociation of symmetrical diazo compounds may be stepwise.⁷ A derivative has been developed that decomposes to initiate radical reactions at room temperature, 2,2'-azobis(2,4-dimethyl-4-methoxyvaleronitrile), **3**.⁸ Water soluble azo compounds are known, and can be used as radical initiators.⁹ Other sources of useful radicals are available. Alkyl hypochlorites (R-O-Cl) generate chlorine radicals (Cl•) and alkoxy radicals (RO•) when heated.¹⁰ Heating *N*-alkoxydithiocarbamates is another useful source of alkoxy radicals, RO•.¹¹

Note that aldehydes can also be a source of acyl radicals ($\bullet\text{C}=\text{O}$) via reaction with transition metal salts such as Mn(III) acetate or Fe(II) compounds.¹² Another useful variation employs imidoyl radicals as synthons for unstable aryl radicals.¹³

The second step involves the *destruction* of free radicals. This usually happens by a process opposite to the first, namely, a combination of two like or unlike radicals to form a new bond:¹⁴

This type of step is called *termination*, and it ends the reaction as far as these particular radicals are concerned.¹⁵ However, it is not often that termination follows *directly* upon initiation. The reason is that most radicals are very reactive and will react with the first available species with which they come in contact. In the usual situation, in which the concentration of radicals is low, this is much more likely to be a molecule than another radical. When a radical (which has an odd number of electrons) reacts with a molecule (which has an even number), the total number of electrons in the products must be odd. The product in a particular step of this kind may be one particle, as in the addition of a radical to a π -bond, which in this case is

another free radical, **4**; or abstraction of an atom such as hydrogen to give two particles, $\text{R}-\text{H}$ and the new radical $\text{R}'\cdot$.

In this latter case, one particle must be a neutral molecule and one a free radical. In both of these examples, a *new radical is generated*. This type of step is called *propagation*, since the newly formed radical can now react with another molecule and produce another radical, and so on, until two radicals do meet each other and terminate the sequence. The process just described is called a *chain reaction*,¹⁶ and there may be hundreds or thousands of propagation steps between an initiation and a termination. Two other types of propagation reactions do not involve a

¹⁴For a review of the stereochemistry of this type of combination reaction, see Porter, N.A.; Krebs, P.J. *Top. Stereochem.* **1988**, *18*, 97.

¹⁵Another type of termination is disproportionation (see p. 280).

¹⁶For a discussion of radical chain reactions from a synthetic point of view, see Walling, C. *Tetrahedron* **1985**, *41*, 3887.

molecule at all. These are (1) cleavage of a radical into, necessarily, a radical and a molecule and (2) rearrangement of one radical to another (see Chapter 18). When radicals are highly reactive, for example, alkyl radicals, chains are long, since reactions occur with many molecules; but with radicals of low reactivity, for example, aryl radicals, the radical may be unable to react with anything until it meets another radical, so that chains are short, or the reaction may be a nonchain process. In any particular chain process, there is usually a wide variety of propagation and termination steps. Because of this, these reactions lead to many products and are often difficult to treat kinetically.¹⁷

A useful variation of propagation and termination combines the two processes. When a carbon radical (R•) is generated in the presence of tributyltin hydride (*n*-Bu₃SnH), a hydrogen atom is transferred to the radical to give R-H and a new radical, *n*-Bu₃Sn•. The tin radical reacts with a second tin radical to give *n*-Bu₃Sn-Sn-*n*-Bu₃. The net result is that the carbon radical is reduced to give the desired product and the tin dimer can be removed from the reaction. Tin hydride transfers a hydrogen atom in a chain propagation sequence that produces a new radical, but terminates the carbon radical sequence. Dimerization of the tin radical then terminates that radical process. Silanes, such as triethylsilane (Et₃SiH), has also been used as an effective radical reducing agent.¹⁸ The rate constants for the reaction of both tributyltin hydride and (Me₃Si)₃Si-H with acyl radical has been measured and the silane quenches the radical faster than the tin hydride.¹⁹ bis(Tri-*n*-butylstannyl)benzopinacolate has also been used as a thermal source of *n*-Bu₃Sn•, used to mediate radical reactions.²⁰

The following are some general characteristics of free-radical reactions:²¹

1. Reactions are fairly similar whether they are occurring in the vapor or liquid phase, though solvation of free radicals in solution does cause some differences.²²
2. They are largely unaffected by the presence of acids or bases or by changes in the polarity of solvents, except that nonpolar solvents may suppress competing ionic reactions.

3. They are initiated or accelerated by typical free-radical sources, such as the peroxides, referred to, or by light. In the latter case, the concept of quantum yield applies (p. 349). Quantum yields can be quite high, for example, 1000, if each quantum generates a long chain, or low, in the case of nonchain processes.
4. Their rates are decreased or the reactions are suppressed entirely by substances that scavenge free radicals, for example, nitric oxide, molecular oxygen, or benzoquinone. These substances are called *inhibitors*.²³

This chapter discusses free-radical substitution reactions. Free-radical additions to unsaturated compounds and rearrangements are discussed in Chapters 15 and 18, respectively. Fragmentation reactions are covered, in part, in Chapter 17. In addition, many of the oxidation–reduction reactions considered in Chapter 19 involve free-radical mechanisms. Several important types of free-radical reactions do not usually lead to reasonable yields of pure products and are not generally treated in this book. Among these are polymerizations and high-temperature pyrolyses.

Free-Radical Substitution Mechanisms²⁴

In a free-radical substitution reaction

there must first be a cleavage of the substrate RX so that R• radicals are produced. This can happen by a spontaneous cleavage

or it can be caused by light or heat, or, more often, there is no actual cleavage, but R• is produced by an *abstraction* of another atom, X but the radical W•

The radical W• is produced by adding a compound, such as a peroxide, that spontaneously forms free radicals. Such a compound is called an *initiator* (see above). Once R• is formed, it can go to product in two ways, by another atom abstraction, such as the reaction with A–B to form R–A and a new radical B•

Another reaction is coupling with another radical to form the neutral product R–Y.

²³For a review of the action of inhibitors, see Denisov, E.T.; Khudyakov, I.V. *Chem. Rev.* **1987**, *87*, 1313.

²⁴For a review, see Poutsma, M.L., in Kochi, J.K. *Free Radicals*, Vol. 2, Wiley, NY, **1973**, pp. 113–158.

In a reaction with a moderately long chain, much more of the product will be produced by abstraction (4) than by coupling (5). Cleavage steps like (2) have been called S_{H1} (H for homolytic), and abstraction steps like (3) and (4) have been called S_{H2} ; reactions can be classified as S_{H1} or S_{H2} on the basis of whether RX is converted to R by (2) or (3).²⁵ Most chain substitution mechanisms follow the pattern (3), (4), (3), (4)••• Chains are long and reactions go well where both (3) and (4) are energetically favored (no worse than slightly endothermic (see pp. 944, 959). The IUPAC designation of a chain reaction that follows the pattern (3),(4)••• is $A_rD_r + A_rD_r$ (R stands for radical).

With certain radicals the transition state in an abstraction reaction has some polar character. For example, consider the abstraction of hydrogen from the methyl group of toluene by a bromine atom. Since bromine is more electronegative than carbon, it is reasonable to assume that in the transition state there is a separation of charge, with a partial negative charge on the halogen and a partial positive charge on the carbon:

Evidence for the polar character of the transition state is that electron-withdrawing groups in the para position of toluene (which would destabilize a positive charge) decrease the rate of hydrogen abstraction by bromine while electron-donating groups increase it.²⁶ However, substituents have a smaller effect here ($\rho \sim -1.4$) than they do in reactions where a completely ionic intermediate is involved, for example, the S_N1 mechanism (see p. 487). Other evidence for polar transition states in radical abstraction reactions is mentioned on p. 948. For abstraction by radicals such as methyl or phenyl, polar effects are very small or completely absent. For example, rates of hydrogen abstraction from ring-substituted toluenes by the methyl radical were relatively unaffected by the presence of electron-donating or electron-withdrawing substituents.²⁷ Those radicals (e.g., $\text{Br}\cdot$) that have a tendency to abstract electron-rich hydrogen atoms are called *electrophilic radicals*.

When the reaction step $R-X \rightarrow R\cdot$ takes place at a chiral carbon, racemization is almost always observed because free radicals do not retain configuration. Exceptions to this rule are found at cyclopropyl substrates, where both inversion²⁸ and retention²⁹ of configuration have been reported, and in the reactions mentioned on p. 942. Enantioselective radical processes have been reviewed.³⁰

Mechanisms at an Aromatic Substrate³¹

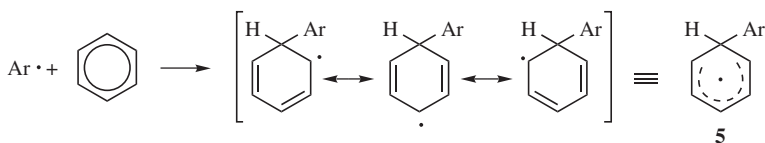

When R in reaction (1) is aromatic, the simple abstraction mechanism just discussed may be operating, especially in gas-phase reactions. However, mechanisms of this type cannot account for all reactions of aromatic substrates. In processes, such as the following (see **13-27**, **14-17**, and **14-18**):

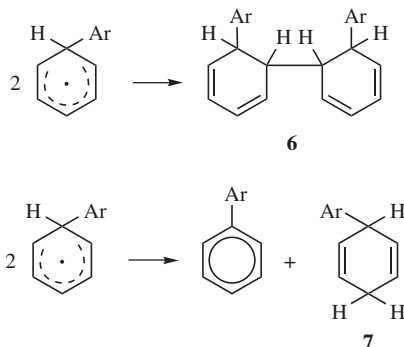

which occur in solution, the coupling of two rings cannot be explained on the basis of a simple abstraction

since, as discussed on p. 944, abstraction of an entire group, such as phenyl, by a free radical is very unlikely. The products can be explained by a mechanism similar to that of electrophilic and nucleophilic aromatic substitution. In the first step, the radical attacks the ring in much the same way as would an electrophile or a nucleophile:

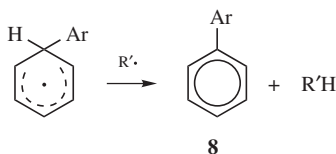

The intermediate radical **5** is relatively stable because of the resonance. The reaction can terminate in three ways: by simple coupling to give **6**, by disproportionation to give **7**,

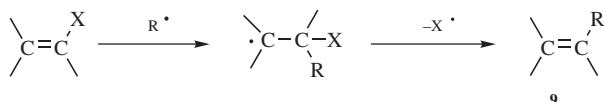

³¹For reviews, see Kobrina, L.S. *Russ. Chem. Rev.* **1977**, *46*, 348; Perkins, M.J., in Kochi, J.K. *Free Radicals*, Vol. 2, Wiley, NY, **1973**, pp. 231–271; Bolton, R.; Williams, G.H. *Adv. Free-Radical Chem.* **1975**, *5*, 1; Nonhebel, D.C.; Walton, J.C. *Free-Radical Chemistry*, Cambridge University Press, London, **1974**, pp. 417–469; Minisci, F.; Porta, O. *Adv. Heterocycl. Chem.* **1974**, *16*, 123; Bass, K.C.; Nababsing, P. *Adv. Free-Radical Chem.* **1972**, *4*, 1; Hey, D.H. *Bull. Soc. Chim. Fr.* **1968**, 1591.

or, if a species ($R'\cdot$) is present that abstracts hydrogen, by abstraction to give **8**.³²

Coupling product **6** is a partially hydrogenated quaterphenyl. Of course, the coupling need not be ortho–ortho, and other isomers can also be formed. Among the evidence for steps (9) and (10) was isolation of compounds of types **6** and **7**,³³ though normally under the reaction conditions dihydrobiphenyls like **7** are oxidized to the corresponding biphenyls. Other evidence for this mechanism is the detection of the intermediate **5** by CIDNP³⁴ and the absence of isotope effects, which would be expected if the rate-determining step were (7), which involves cleavage of the Ar–H bond. In the mechanism just given, the rate-determining step (8) does not involve loss of hydrogen. The reaction between aromatic rings and the HO• radical takes place by the same mechanism. Intramolecular hydrogen-transfer reactions of aryl radicals are known.³⁵ A similar mechanism has been shown for substitution at some vinylic³⁶ and acetylenic substrates, giving the substituted alkene **9**.³⁷ The kinetics of radical heterolysis reactions that form alkene radical cations has been studied.³⁸

This is reminiscent of the nucleophilic tetrahedral mechanism at a vinylic carbon (p. 477).

There are a number of transition-metal mediated coupling reaction of aromatic substrates that probably proceed by radical coupling. It is also likely that many of these reactions do not proceed by free radicals, but rather by metal-mediated radicals or by ligand transfer on the metal. Reactions in these categories were presented

³²Compound **5** can also be oxidized to the arene ArPh by atmospheric O₂. For a discussion of the mechanism of this oxidation, see Narita, N.; Tezuka, T. *J. Am. Chem. Soc.* **1982**, *104*, 7316.

³⁶The reaction of vinyl chloride with Cl[−] favors the σ-route (nucleophilic attack at the σ-bond) over the π-route (nucleophilic attack at the π-bond), but vinyl chloride is not an experimentally viable substrate and cannot be considered as representative for the vinyl S_N2 reaction. The π-route is anticipated in substituted vinylic halide reactions, where electron-withdrawing groups are attached to the vinylic carbon. See Bach, R. D.; Baboul, A. G.; Schlegel, H. B. *J. Am. Chem. Soc.* **2001**, *123*, 5787.

in Chapter 13 for convenient correlation with other displacement reactions of aryl halides, aryl diazonium salts, and so on.

Neighboring-Group Assistance in Free-Radical Reactions

In a few cases, it has been shown that cleavage steps (2) and abstraction steps (3) have been accelerated by the presence of neighboring groups. Photolytic halogenation (**14-1**) is a process that normally leads to mixtures of many products. However, bromination of carbon chains containing a bromine atom occurs with high regioselectivity. Bromination of alkyl bromides gave 84–94% substitution at the carbon adjacent to the bromine already in the molecule.³⁹ This result is especially surprising because, as we will see (p. 947), positions close to a polar group, such as bromine, should actually be *deactivated* by the electron-withdrawing field effect of the bromine. The unusual regioselectivity is explained by a mechanism in which abstraction (3) is assisted by a neighboring bromine atom, as in **10**.⁴⁰

In the normal mechanism, $\text{Br}\cdot$ abstracts a hydrogen from RH , leaving $\text{R}\cdot$. When a bromine is present in the proper position, it assists this process, giving a cyclic intermediate (a *bridged free radical*, **11**).⁴¹ In the final step (very similar to $\text{R}\cdot + \text{Br}_2 \rightarrow \text{RBr} + \text{Br}\cdot$), the ring is broken. If this mechanism is correct, the configuration at the substituted carbon (marked *) should be retained. This has been shown to be the case: optically active 1-bromo-2-methylbutane gave 1,2-dibromo-2-methylbutane with retention of configuration.⁴⁰ Furthermore, when this reaction was carried out in the presence of DBr , the “recovered” 1-bromo-2-methylbutane was found to be deuterated in the 2 position, and its configuration was retained.⁴² This is just what would be predicted if some of the **11** present abstracted D from DBr . There is evidence that Cl can form bridged radicals,⁴³

though ESR spectra show that the bridging is not necessarily symmetrical.⁴⁴ Still more evidence for bridging by Br has been found in isotope effect and other studies.⁴⁵ However, evidence from CIDNP shows that the methylene protons of the β -bromoethyl radical are not equivalent, at least while the radical is present in the radical pair $[\text{PhCOO}\cdot\cdot\text{CH}_2\text{CH}_2\text{Br}]$ within a solvent cage.⁴⁶ This evidence indicates that under these conditions $\text{BrCH}_2\text{CH}_2\cdot$ is not a symmetrically bridged radical, but it could be unsymmetrically bridged. A bridged intermediate has also been invoked, when a bromo group is in the proper position, in the Hunsdiecker reaction⁴⁷ (**14-30**), and in abstraction of iodine atoms by the phenyl radical.⁴⁸ Participation by other neighboring groups (e.g. SR, SiR₃, SnR₃) has also been reported.⁴⁹

REACTIVITY

Reactivity for Aliphatic Substrates⁵⁰

In a chain reaction, the step that determines what the product will be is most often an abstraction step. What is abstracted by a free radical is almost never a tetra-⁵¹ or tervalent atom⁵² (except in strained systems, see p. 1027)⁵³ and seldom a divalent one.⁵⁴ Nearly always it is univalent, and so, for organic compounds, it is hydrogen or halogen. For example, a reaction between a chlorine atom and ethane gives an

ethyl radical, not a hydrogen atom:

The principal reason for this is steric. A univalent atom is much more exposed to attack by the incoming radical than an atom with a higher valence. Another reason is that in many cases abstraction of a univalent atom is energetically more favored. For example, in the reaction given above, a C₂H₅—H bond is broken ($D = 100 \text{ kcal mol}^{-1}$, 419 kJ mol^{-1} , from Table 5.3) whichever pathway is taken, but in the former case an H—Cl bond is formed ($D = 103 \text{ kcal mol}^{-1}$, 432 kJ mol^{-1}) while in the latter case it is a C₂H₅—Cl bond ($D = 82 \text{ kcal mol}^{-1}$, 343 kJ mol^{-1}). Thus the first reaction is favored because it is exothermic by 3 kcal mol^{-1} ($100-103$) [13 kJ mol^{-1} ($419-432$)], while the latter is endothermic by 18 kcal mol^{-1} ($100-82$) [76 kJ mol^{-1} ($419-343$)].⁵⁵ However, the steric reason is clearly more important, because even in cases where ΔH is not very different for the two possibilities, the univalent atom is chosen.⁵⁶ *Ab initio* studies have probed the transition structures for radical hydrogen abstractions.⁵⁷

Most studies of aliphatic reactivity have been made with hydrogen as the leaving atom and chlorine atoms as the abstracting species.⁵⁸ In these reactions, every hydrogen in the substrate is potentially replaceable and mixtures are usually obtained. However, the abstracting radical is not totally unselective, and some positions on a molecule lose hydrogen more easily than others. *Ab initio* studies have studied the factors controlling hydrogen abstraction by radicals.⁵⁹ For hydrogen abstraction by the *tert*-butoxy radical (*t*-Bu—O•) the factors that influence rate in their order of importance are structure of the radical > substituent effects⁶⁰ > solvent effects.⁶¹ We discuss the position of attack under several headings:⁶²

⁵⁵The parameter ΔH for a free-radical abstraction reaction can be regarded simply as the difference in D values for the bond being broken and the one formed.

TABLE 14.1. Relative Susceptibility to Attack by Cl• of Primary, Secondary, and Tertiary Positions at 100 and 600°C in the Gas Phase⁶³

Temperature, °C	Primary	Secondary	Tertiary
100	1	4.3	7.0
600	1	2.1	2.6

1. *Alkanes*. The tertiary hydrogens of an alkane are the ones preferentially abstracted by almost any radical, with secondary hydrogens being next preferred. This is in the same order as *D* values for these types of C–H bonds (Table 5.3). The extent of the preference depends on the selectivity of the abstracting radical and on the temperature. Table 14.1 shows⁶³ that at high temperatures selectivity decreases, as might be expected.⁶⁴ An example of the effect of radical selectivity may be noted in a comparison of fluorine atoms with bromine atoms. For the former, the ratio of primary to tertiary abstraction (of hydrogen) is 1:1.4, while for the less reactive bromine atom this ratio is 1:1600. With certain large radicals there is a steric factor that may change the selectivity pattern. For example, in the photochemical chlorination of isopentane in H₂SO₄ with *N*-chloro-di-*tert*-butylamine and *N*-chloro-*tert*-butyl-*tert*-pentylamine, the primary hydrogens are abstracted 1.7 times *faster* than the tertiary hydrogen.⁶⁵ In this case, the attacking radicals (the radical ions R₂NH•⁺, see p. 958) are bulky enough for steric hindrance to become a major factor.

Cyclopropylcarbinyl radicals (**12**) are alkyl radicals, but they undergo rapid ring opening to give butenyl radicals.⁶⁶ The rate constant for this process has been measured by picosecond radical kinetic techniques to be in the range of $10^7 M^{-1} s^{-1}$ for the parent⁶⁷ to $10^{10} M^{-1} s^{-1}$ for substituted derivatives.⁶⁸ Cyclobutylcarbinyl radicals undergo the cyclobutylcarbinyl to

4-pentenyl radical process,⁶⁹ but examples are generally limited to the parent system and phenyl-substituted derivatives.⁷⁰ Cyclization of the 4-pentenyl radical is usually limited to systems where a stabilized radical can be formed.⁷¹ The effect of substituents has been studied.⁷² This process has been observed in bicyclo[4.1.0]heptan-4-ones.⁷³

The rate of the ring-opening reaction of **5**,⁷⁴ and other substrates have been determined using an indirect method for the calibration⁷⁵ of fast radical reactions, applicable for radicals with lifetimes as short as 1 ps.⁷⁶ This 'radical clock'⁷⁷ method is based on the use of Barton's use of pyridine-2-thione-*N*-oxycarbonyl esters as radical precursors and radical trapping by the highly reactive thiophenol and benzeneselenol.⁷⁸ A number of radical clock substrates are known.⁷⁹ Other radical clock processes include: racemization of radicals with chiral conformations,⁸⁰ one-carbon ring expansion in cyclopentanones,⁸¹ norcarane and spiro[2,5]octane,⁸² α - and β -thujone radical rearrangements,⁸³ and cyclopropylcarbinyl radicals or alkoxy carbonyl radicals containing stabilizing substituents.⁸⁴

2. *Alkenes*. When the substrate molecule contains a double bond, treatment with chlorine or bromine usually leads to addition rather than substitution. However, for other radicals (and even for chlorine or bromine atoms when they do abstract a hydrogen) the position of attack is perfectly clear. Vinylic hydrogens are practically never abstracted, and allylic hydrogens are greatly preferred to other positions of the molecule. Allylic hydrogen abstraction from a cyclic alkenes is usually faster than abstraction from an acyclic alkene.⁸⁵ This is generally attributed⁸⁶ to resonance stabilization of the allylic radical, **13**. As might be expected, allylic rearrangements (see p. 469) are common in these cases.⁸⁷

3. *Alkyl Side Chains of Aromatic Rings*. The preferential position of attack on a side chain is usually the one to the ring. Both for active radicals, such as chlorine and phenyl, and for more selective ones, such as bromine, such attack is faster than that at a primary carbon, but for the active radicals benzylic attack is slower than for tertiary positions, while for the selective ones it is faster. Two or three aryl groups on a carbon activate its hydrogens even more, as would be expected from the resonance involved. These statements can be illustrated by the following abstraction ratios:⁸⁸

	Me-H	MeCH ₂ -H	Me ₂ CH-H	Me ₃ C-H	PhCH ₂ -H	Ph ₂ CH-H	Ph ₃ C-H
Br	0.0007	1	220	19,400	64,000	1.1 × 10 ⁶	6.4 × 10 ⁶
Cl	0.004	1	4.3	6.0	1.3	2.6	9.5

However, many anomalous results have been reported for these substrates. The benzylic position is not always the most favored. One thing certain is that *aromatic* hydrogens are seldom abstracted if there are aliphatic ones to compete (note from Table 5.3, that *D* for Ph-H is higher than that for any alkyl H bond). Several $\sigma\cdot$ scales (similar to the σ , σ^+ , and σ^- scales discussed in Chapter 9) have been developed for benzylic radicals.⁸⁹

Chem.* **1990**, *55*, 1040.

4. *Compounds Containing Electron-Withdrawing Substituents.* In halogenations, electron-withdrawing groups greatly deactivate adjacent positions. Compounds of the type $Z-CH_2-CH_3$ are attacked predominantly or exclusively at the β position when Z is $COOH$, $COCl$, $COOR$, SO_2Cl , or CX_3 . Such compounds as acetic acid and acetyl chloride are not attacked at all. This is in sharp contrast to electrophilic halogenations (12-4–12-6), where *only* the α position is substituted. This deactivation of a positions is also at variance with the expected stability of the resulting radicals, since they would be expected to be stabilized by resonance similar to that for allylic and benzylic radicals. This behavior is a result of the polar transition states discussed on p. 939. Halogen atoms are electrophilic radicals and look for positions of high electron density. Hydrogens on carbon atoms next to electron-withdrawing groups have low electron densities (because of the field effect of Z) and are therefore shunned. Radicals that are not electrophilic do not display this behavior. For example, the methyl radical is essentially nonpolar and does not avoid positions next to electron-withdrawing groups; relative rates of abstraction at the α and β carbons of propionic acid are:⁹⁰

	CH ₃ -CH ₂ -COOH	
Me•	1	7.8
Cl•	1	0.02

It is possible to generate radicals adjacent to electron-withdrawing groups. Radical **14** can be generated and it undergoes coupling reactions with little selectivity. When **15** is generated, however, it rapidly disproportionates rather than couples, giving the corresponding alkene and alkane.⁹¹ Such radicals have also been shown to have a conformational preference for orientation of the orbital containing the single electron. In such cases, hydrogen abstraction proceeds with good stereoselectivity.⁹²

Some radicals, for example, *tert*-butyl,⁹³ benzyl,⁹⁴ and cyclopropyl,⁹⁵ are *nucleophilic* (they tend to abstract electron-poor hydrogen atoms). The

phenyl radical appears to have a very small degree of nucleophilic character.⁹⁶ For longer chains, the field effect continues, and the β position is also deactivated to attack by halogen, though much less so than the α position. We have already mentioned (p. 939) that abstraction of an α hydrogen atom from ring-substituted toluenes can be correlated by the Hammett equation.

5. *Stereoelectronic Effects.* On p. 1258, we will see an example of a stereoelectronic effect. It has been shown that such effects are important where a hydrogen is abstracted from a carbon adjacent to a C—O or C—N bond. In such cases, hydrogen is abstracted from C—H bonds that have a relatively small dihedral angle ($\sim 30^\circ$) with the unshared orbitals of the O or N much more easily than from those with a large angle ($\sim 90^\circ$). For example, the starred hydrogen of **16** was abstracted ~ 8 times faster than the starred hydrogen of **17**.⁹⁷

The presence of an OR or SiR₃ substituent β - to the carbon bearing the radical accelerates the rate of halogen abstraction.⁹⁸

Abstraction of a halogen has been studied much less,⁹⁹ but the order of reactivity is RI > RBr > RCl \gg RF.

There are now many cases where free-radical reactions are promoted by transition metals.¹⁰⁰

Reactivity at a Bridgehead¹⁰¹

Many free-radical reactions have been observed at bridgehead carbons, as in formation of bromide **18** (see **14-30**),¹⁰² demonstrating that the free radical need not be planar. However, treatment of norbornane with sulfonyl chloride and benzoyl

peroxide gave mostly 2-chloronorbornane, though the bridgehead position is tertiary.¹⁰³ So, while bridgehead free-radical substitution is possible, it is not preferred, presumably because of the strain involved.¹⁰⁴

Reactivity in Aromatic Substrates

Free-radical substitution at an aromatic carbon seldom takes place by a mechanism in which a hydrogen is abstracted to give an aryl radical. Reactivity considerations here are similar to those in Chapters 11 and 13; that is, we need to know which position on the ring will be attacked to give the intermediate, **19**.

The obvious way to obtain this information is to carry out reactions with various Z groups and to analyze the products for percent ortho, meta, and para isomers, as has so often been done for electrophilic substitution. However, this procedure is much less accurate in the case of free-radical substitutions because of the many side reactions. It may be, for example, that in a given case the ortho position is more reactive than the para, but the intermediate from the para attack may go on to product while that from ortho attack gives a side reaction. In such a case, analysis of the three products does not give a true picture of which position is most susceptible to attack. The following generalizations can nevertheless be drawn, though there has been much controversy over just how meaningful such conclusions are¹⁰⁵

1. All substituents increase reactivity at ortho and para positions over that of benzene. There is no great difference between electron-donating and electron-withdrawing groups.
2. Reactivity at meta positions is usually similar to that of benzene, perhaps slightly higher or lower. This fact, coupled with the preceding one, means that all substituents are activating and ortho–para directing; none are deactivating or (chiefly) meta directing.

TABLE 14.2. Partial Rate Factors for Attack of Substituted Benzenes by Phenyl Radicals Generated from Bz_2O_2 ¹⁰⁸

Z	Partial Rate Factor		
	<i>o</i>	<i>m</i>	<i>p</i>
H	1	1	1
NO ₂	5.50	0.86	4.90
CH ₃	4.70	1.24	3.55
CMe ₃	0.70	1.64	1.81
Cl	3.90	1.65	2.12
Br	3.05	1.70	1.92
MeO	5.6	1.23	2.31

3. Reactivity at ortho positions is usually somewhat greater than at para positions, except where a large group decreases ortho reactivity for steric reasons.
4. In direct competition, electron-withdrawing groups exert a somewhat greater influence than electron-donating groups. Arylation of para-disubstituted compounds $\text{XC}_6\text{H}_4\text{Y}$ showed that substitution ortho to the group X became increasingly preferred as the electron-withdrawing character of X increases (with Y held constant).¹⁰⁶ The increase could be correlated with the Hammett σ_p values for X.
5. Substituents have a much smaller effect than in electrophilic or nucleophilic substitution; hence the partial rate factors (see p. 677) are not great.¹⁰⁷ Partial rate factors for a few groups are given in Table 14.2.¹⁰⁸
6. Although hydrogen is the leaving group in most free-radical aromatic substitutions, ipso attack (p. 671) and ipso substitution (e.g., with Br, NO₂, or CH₃CO as the leaving group) have been found in certain cases.¹⁰⁹

Reactivity in the Attacking Radical¹¹⁰

We have already seen that some radicals are much more selective than others (p. 944). The bromine atom is so selective that when only primary hydrogens are available, as in neopentane or *tert*-butylbenzene, the reaction is slow or nonexistent; and isobutane can be selectively brominated to give *tert*-butyl bromide in high yields.

TABLE 14.3. Some Common Free Radicals in Decreasing Order of Activity^a

Radical	E		Radical	E	
	kcal mol ⁻¹ e	kJ mol ⁻¹ e		kcal mol ⁻¹	kJ mol ⁻¹
F•	0.3	1.3	H•	9.0	38
Cl•	1.0	4.2	Me•	11.8	49.4
MeO•	7.1	30	Br•	13.2	55.2
CF ₃ •	7.5	31			

^aThe *E* values represent activation energies for the reaction

i-Pr• is less active than Me• and *t*-Bu• still less so.¹¹³

However, toluene reacts with bromine atoms instantly. Bromination of other alkylbenzenes, for example, ethylbenzene and cumene, takes place exclusively at the α position,¹¹¹ emphasizing the selectivity of Br•. The dissociation energy *D* of the C–H bond is more important for radicals of low reactivity than for highly reactive radicals, since bond breaking in the transition state is greater. Thus, bromine shows a greater tendency than chlorine to attack α to an electron-withdrawing group because the energy of the C–H bond there is lower than in other places in the molecule.

Some radicals, for example, triphenylmethyl, are so unreactive that they abstract hydrogens very poorly if at all. Table 14.3 lists some common free radicals in approximate order of reactivity.¹¹²

It has been mentioned that some free radicals (e.g., chloro) are electrophilic and some (e.g., *tert*-butyl) are nucleophilic. It must be borne in mind that these tendencies are relatively slight compared with the electrophilicity of a positive ion or the nucleophilicity of a negative ion. The predominant character of a free radical is neutral, whether it has slight electrophilic or nucleophilic tendencies.

The Effect of Solvent on Reactivity¹¹⁴

As noted earlier, the solvent usually has little effect on free-radical substitutions in contrast to ionic ones: indeed, reactions in solution are often quite similar in character to those in the gas phase, where there is no solvent at all. However, in certain cases the solvent *can* make an appreciable difference. Chlorination of 2,3-dimethylbutane in aliphatic solvents gave about 60% (CH₃)₂CHCH(CH₃)CH₂Cl

and 40% $(\text{CH}_3)_2\text{CHCCl}(\text{CH}_3)_2$, while in aromatic solvents the ratio became $\sim 10:90$.¹¹⁵ This result is attributed to complex formation between the aromatic solvent and the

20

chlorine atom that makes the chlorine more selective.¹¹⁶ This type of effect is not found in cases where the differences in ability to abstract the atom are caused by field effects of electron-withdrawing groups (p. 948). In such cases, aromatic solvents make little difference.¹¹⁷ The complex **20** has been detected¹¹⁸ as a very short-lived species by observation of its visible spectrum in the pulse radiolysis of a solution of benzene in CCl_4 .¹¹⁹ Differences caused by solvents have also been reported in reactions of other radicals.¹²⁰ Some of the anomalous results obtained in the chlorination of aromatic side chains (p. 947) can also be explained by this type of complexing, in this case not with the solvent but with the reacting species.¹²¹ Much smaller, though real, differences in selectivity have been found when the solvent in the chlorination of 2,3-dimethylbutane is changed from an alkane to CCl_4 .¹²² However, these differences are not caused by formation of a complex between $\text{Cl}\cdot$ and the solvent. There are cases,

¹¹⁸It has been contended that another species, a chlorocyclohexadienyl radical (the structure of which is the same as **5**, except that Cl replaces Ar), can also be attacking when the solvent is benzene: Skell, P.S.; Baxter III, H.N.; Taylor, C.K. *J. Am. Chem. Soc.* **1983**, *105*, 120; Skell, P.S.; Baxter III, H.N.; Tanko, J.M.; Chebolu, V. *J. Am. Chem. Soc.* **1986**, *108*, 6300. however, where the rate of reaction for trapping a radical depends on the polarity of the solvent, particularly in water.¹²³

REACTIONS

The reactions in this chapter are classified according to leaving group. The most common leaving groups are hydrogen and nitrogen (from the diazonium ion); these are considered first.

HYDROGEN AS LEAVING GROUP

A. Substitution by Halogen

14-1 Halogenation at an Alkyl Carbon¹²⁴

Halogenation or Halo-de-hydrogenation

Alkanes can be chlorinated or brominated by treatment with chlorine or bromine in the presence of visible or UV light.¹²⁵ These reactions require a radical chain initiator, light, or higher temperatures.¹²⁶ The reaction can also be applied to alkyl chains containing many functional groups. The chlorination reaction is usually not useful for preparative purposes precisely because it is so general: Not only does substitution take place at virtually every alkyl carbon in the molecule, but di- and polychloro substitution almost invariably occur even if there is a large molar ratio of substrate to halogen.

When functional groups are present, the principles are those outlined on p. 945; favored positions are those α to aromatic rings, while positions α to electron-withdrawing groups are least likely to be substituted. Tertiary carbons are most likely to be attacked and primary least. Positions α to an OR group are very readily attacked. Nevertheless, mixtures are nearly always obtained. This can be contrasted to the regioselectivity of electrophilic halogenation (12-4-12-6), which always takes place α to a carbonyl group (except when the reaction is catalyzed by AgSbF_6 ; see following). Of course, if a *mixture* of chlorides is wanted, the reaction is usually

¹²³Tronche, C.; Martinez, F.N.; Horner, J.H.; Newcomb, M.; Senn, M.; Giese, B. *Tetrahedron Lett.* **1996**, 37, 5845.

¹²⁶Hill, C.L. *Activation and Functionalization of Alkanes*, Wiley, NY, **1989**.

quite satisfactory. For obtaining pure compounds, the chlorination reaction is essentially limited to substrates with only one type of replaceable hydrogen (e.g., ethane, cyclohexane, neopentane). The most common are methylbenzenes and other substrates with methyl groups on aromatic rings, since few cases are known where halogen atoms substitute at an aromatic position.¹²⁷ Of course, ring substitution *does* take place in the presence of a positive-ion-forming catalyst (11-10). In addition to mixtures of various alkyl halides, traces of other products are obtained. These include H₂, alkenes, higher alkanes, lower alkanes, and halogen derivatives of these compounds. Solvent plays an important role in this process.¹²⁸

The bromine atom is much more selective than the chlorine atom. As indicated on p. 952, it is often possible to brominate tertiary and benzylic positions selectively. High regioselectivity can also be obtained where the neighboring-group mechanism (p. 942) can operate.

As already mentioned, halogenation can be performed with chlorine or bromine. Fluorine has also been used,¹²⁹ but seldom, because it is too reactive and hard to control.¹³⁰ It often breaks carbon chains down into smaller units, a side reaction that sometimes becomes troublesome in chlorinations too. Fluorination¹³¹ has been achieved by the use of chlorine trifluoride ClF₃ at -75°C.¹³² For example, cyclohexane gave 41% fluorocyclohexane and methylcyclohexane gave 47% 1-fluoro-1-methylcyclohexane. Fluoroxytrifluoromethane CF₃OF fluorinates tertiary positions of certain molecules in good yields with high regioselectivity.¹³³ For example, adamantane gave 75% 1-fluoroadamantane. Fluorine at -70°C, diluted with N₂,¹³⁴ and bromine trifluoride at 25–35°C¹³⁵ are also highly regioselective for

tertiary positions. These reactions probably have electrophilic,¹³⁶ not free-radical mechanisms. In fact, the success of the F₂ reactions depends on the suppression of free radical pathways, by dilution with an inert gas, by working at low temperatures, and/or by the use of radical scavengers.

Iodine can be used if the activating light has a wavelength of 184.9 nm,¹³⁷ but iodinations using I₂ alone are seldom attempted, largely because the HI formed reduces the alkyl iodide. The direct free-radical halogenation of aliphatic hydrocarbons with iodine is significantly endothermic relative to the other halogens, and the requisite chain reaction does not occur.¹³⁸ On the other hand, when iodine, CCl₄·2 AlI₃ react with an alkane in dibromomethane at -20°C, good yields of the iodoalkane are obtained.¹³⁹ The reaction of an alkane with *tert*-butylhypoiodite (*t*-BuOI) at 40°C gave the iodoalkane in good yield.¹⁴⁰ The reaction of alkanes with iodine and PhI(OAc)₂ generates the iodoalkane.¹⁴¹ A radical protocol was developed using Cl₄ with base. Cyclohexane could be iodinated, for example, with Cl₄ in the presence of powdered NaOH.¹⁴² The reaction led to the use of iodoform on solid NaOH as the iodination reagent of choice. α -Iodo ethers and α -iodolactones have been prepared from the parent ether or lactone via treatment with Et₄N⁺·4 HF under electrolytic conditions.¹⁴³

Many other halogenation agents have been employed, the most common of which is sulfuryl chloride SO₂Cl₂.¹⁴⁴ A mixture of Br₂ and HgO is a more active brominating agent than bromine alone.¹⁴⁵ The actual brominating agent in this case is believed to be bromine monoxide Br₂O. Among other agents used have been *N*-bromosuccinimide (NBS, see **14-3**), CCl₄,¹⁴⁶ BrCCl₃,¹⁴⁷ PCl₅,¹⁴⁸ and *N*-haloamines and sulfuric acid.¹⁴⁹ In all these cases, a chain-initiating catalyst is required, usually peroxides or UV light.

A base-induced bromination has been reported. 2-Methyl butane reacts with 50% aq. NaOH and CBr₄, in a phase-transfer catalyst, to give a modest yields of 2-bromo-2-methylbutane.¹⁵⁰

When chlorination is carried out with *N*-haloamines and sulfuric acid (catalyzed by either uv light or metal ions), selectivity is much greater than with other reagents.¹⁴⁹ In particular, alkyl chains are chlorinated with high regioselectivity at the position next to the end of the chain (the ω - 1 position).¹⁵¹ Some typical selectivity values are¹⁵²

CH ₃ -CH ₂ -CH ₂ -CH ₂ -CH ₂ -CH ₂ -CH ₃	Ref. 153
1 56 29 14	
CH ₃ -CH ₂ -CH ₂ -CH ₂ -CH ₂ -CH ₂ -CH ₂ -CH ₂ -OH	Ref. 154
1 92 3 1 1 2 0 0	
CH ₃ -CH ₂ -CH ₂ -CH ₂ -CH ₂ -CH ₂ -COOMe	Ref. 155
3 72 20 4 1 0	

Furthermore, di- and polychlorination are much less prevalent. Dicarboxylic acids are predominantly chlorinated in the middle of the chain,¹⁵⁶ and adamantane and bicyclo[2.2.2]octane at the bridgeheads¹⁵⁷ by this procedure. The reasons for the high ω - 1 specificity are not clearly understood.¹⁵⁸ Alkyl bromides can be regioselectively chlorinated one carbon away from the bromine (to give *vic*-bromochlorides) by treatment with PCl₅.¹⁵⁹ Alkyl chlorides can be converted to *vic*-dichlorides by treatment with MoCl₅.¹⁶⁰ Enhanced selectivity at a terminal position of *n*-alkanes has been achieved by absorbing the substrate onto a pentasil zeolite.¹⁶¹ In another regioselective chlorination, alkanesulfonamides

¹⁵⁰Schreiner, P.R.; Lauenstein, O.; Kolomitsyn, I.V.; Nadi, S.; Kokin, A.A. *Angew. Chem. Int. Ed.* **1998**, *37*, 1895.

¹⁵¹The ω - 1 regioselectivity diminishes when the chains are >10 carbons; see Deno, N.C.; Jedziniak, E.J. *Tetrahedron Lett.* **1976**, 1259; Konen, D.A.; Maxwell, R.J.; Silbert, L.S. *J. Org. Chem.* **1979**, *44*, 3594.

¹⁵²The ω - 1 selectivity values shown here may actually be lower than the true values because of selective solvolysis of the ω - 1 chlorides in concentrated H₂SO₄; see Deno, N.C.; Pohl, D.G. *J. Org. Chem.* **1975**, *40*, 380.

$\text{RCH}_2\text{-CH}_2\text{CH}_2\text{SO}_2\text{NHR}'$ are converted primarily to $\text{RCHClCH}_2\text{CH}_2\text{SO}_2\text{NHR}'$ by sodium peroxydisulfate $\text{Na}_2\text{S}_2\text{O}_8$ and CuCl_2 .¹⁶² For regioselective chlorination at certain positions of the steroid nucleus, see **19-2**.

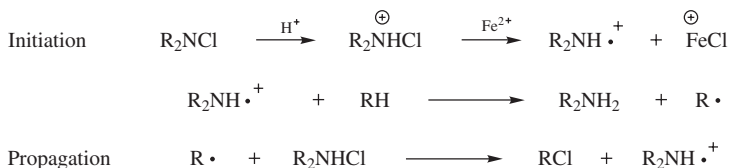

In almost all cases, the mechanism involves a free-radical chain:

When the reagent is halogen, initiation occurs as shown above.¹⁶³ When it is another reagent, a similar cleavage occurs (catalyzed by light or, more commonly, peroxides), followed by propagation steps that do not necessarily involve abstraction by halogen. For example, the propagation steps for chlorination by *tert*-butyl hypochlorite (*t*-BuOCl) have been formulated as¹⁶⁴

and the abstracting radicals in the case of *N*-haloamines are the aminium radical cations $\text{R}_2\text{NH}\cdot^+$ (p. 693), with the following mechanism (in the case of initiation by Fe^{2+}):¹⁴⁹

This mechanism is similar to that of the Hofmann–Löffler reaction (**18-40**).

The two propagation steps shown above for X_2 are those that lead directly to the principal products (RX and HX), but many other propagation steps are possible and many occur. Similarly, the only termination step shown is the one that leads to RX, but any two radicals may combine ($\cdot\text{H}$, $\cdot\text{CH}_3$, $\cdot\text{Cl}$, $\cdot\text{CH}_2\text{CH}_3$ in all combinations).

¹⁶²Nikishin, G.I.; Troyansky, E.I.; Lazareva, M.I. *Tetrahedron Lett.* **1985**, 26, 3743.

¹⁶³There is evidence (unusually high amounts of multiply chlorinated products) that under certain conditions in the reaction of RH with Cl_2 , the products of the second propagation step ($\text{RX} + \text{X}\cdot$) are enclosed within a solvent cage. See Skell, P.S.; Baxter III, H.N. *J. Am. Chem. Soc.* **1985**, 107, 2823; Raner, K.D.; Luszyk, J.; Ingold, K.U. *J. Am. Chem. Soc.* **1988**, 110, 3519; Tanko, J.M.; Anderson III, F.E. *J. Am. Chem. Soc.* **1988**, 110, 3525.

Thus, products like H₂, higher alkanes, and higher alkyl halides can be accounted for. When methane is the substrate, the rate-determining step is

since an isotope effect of 12.1 was observed at 0°C.¹⁶⁵ For chlorinations, chains are very long, typically 10⁴–10⁶ propagations before a termination step takes place.

The order of reactivity of the halogens can be explained by energy considerations. For the substrate methane, ΔH values for the two principal propagation steps are

Reaction	kcal mol ⁻¹				kJ mol ⁻¹			
	F ₂	Cl ₂	Br ₂	I ₂	F ₂	Cl ₂	Br ₂	I ₂
CH ₄ + X• → CH ₃ • + HX	-31	+2	+17	+34	-132	+6	+72	+140
CH ₄ + X ₂ → CH ₃ X + X•	-70	-26	-24	-21	-293	-113	-100	-87

In each case, D for CH₃–H is 105 kcal mol⁻¹ (438 kJ mol⁻¹), while D values for the other bonds involved are given in Table 14.4.¹⁶⁶ Fluorine is so reactive¹⁶⁷ that neither uv light nor any other initiation is needed (total $\Delta H = -101$ kcal mol⁻¹; -425 kJ mol⁻¹);¹⁶⁸ while Br₂ and I₂ essentially do not react with methane. The second step is exothermic in all four cases, but it cannot take place before the first, and it is this step that is very unfavorable for Br₂ and I₂. It is apparent that the most important single factor causing the order of halogen reactivity to be F₂ > Cl₂ > Br₂ > I₂ is the decreasing strength of the HX bond in the order HF > HCl > HBr > HI. The increased reactivity of secondary and tertiary positions is in accord with the decrease in D values for R–H in the order primary > secondary > tertiary (Table 5.3). (Note that for chlorination step 1 is exothermic for practically all substrates other than CH₄, since most other aliphatic C–H bonds are weaker than those in CH₄.)

Bromination and chlorination of alkanes and cycloalkanes can also take place by an electrophilic mechanism if the reaction is catalyzed by AgSbF₆.¹⁶⁹ Direct

¹⁶⁶Kerr, J.A., in Weast, R.C. *Handbook of Chemistry and Physics*, 69th ed., CRC Press, Boca Raton, FL, **1988**, pp. F174–F189.

¹⁶⁷It has been reported that the reaction of F atoms with CH₄ at 25 K takes place with practically zero activation energy: Johnson, G.L.; Andrews, L. *J. Am. Chem. Soc.* **1980**, *102*, 5736.

¹⁶⁸For F₂, the following initiation step is possible: F₂ + RH → R• + F• + HF [first demonstrated by Miller, Jr, W.T.; Koch, Jr, S.D.; McLafferty, F.W. *J. Am. Chem. Soc.* **1956**, *78*, 4992]. ΔH for this reaction is equal to the small positive value of 5 kcal mol⁻¹ (21 kJ mol⁻¹). The possibility of this reaction (which does not require an initiator) explains why fluorination can take place without UV light [which would otherwise be needed to furnish the 38 kcal mol⁻¹ (159 kJ mol⁻¹) necessary to break the F–F bond]. Once the reaction has been initiated, the large amount of energy given off by the propagation steps is ample to cleave additional F₂ molecules. Indeed, it is the magnitude of this energy that is responsible for the cleavage of carbon chains by F₂.

CH ₃ -Br	70	293
CH ₃ -I	57	238

chlorination at a vinylic position by an electrophilic mechanism has been achieved with benzeneselenenyl chloride PhSe(O)Cl and AlCl₃ or AlBr₃.¹⁷⁰ However, while some substituted alkenes give high yields of chloro substitution products, others (e.g., styrene) undergo addition of Cl₂ to the double bond (**15-39**).¹³¹ Electrophilic fluorination has already been mentioned (p. 956).

14-2 Halogenation at Silicon

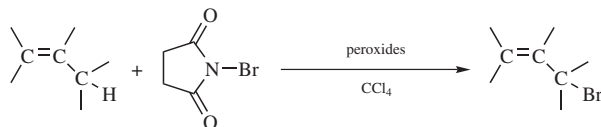

Halogenation or Halo-de-hydrogenation

Just as free-radical halogenation occurs at the carbon of an alkane, via hydrogen abstraction to form the radical, a similar reaction occurs at silicon. When triisopropylsilane (*i*Pr₃Si-H) reacts with *tert*-butyl hypochlorite at -10°C, the product is triisopropylchlorosilane (*i*Pr₃Si-Cl).¹⁷¹

14-3 Allylic and Benzylic Halogenation

Halogenation or Halo-de-hydrogenation

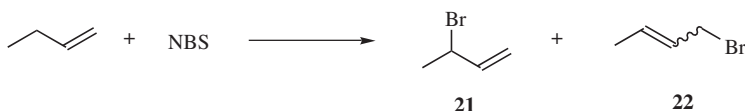

¹⁷⁰Kamigata, N.; Satoh, T.; Yoshida, M. *Bull. Chem. Soc. Jpn.* **1988**, *44*, 449.

¹⁷¹Chawla, R.; Larson, G.L. *Synth. Commun.* **1999**, *29*, 3499.

This reaction is a special case of **14-1**, but is important enough to be treated separately.¹⁷² Alkenes can be halogenated in the allylic position and also a benzylic position by a number of reagents, of which NBS¹⁷³ is by far the most common. When this reagent is used, the reaction is known as *Wohl-Ziegler bromination*. A nonpolar solvent is used, most often CCl₄, but the reaction has been done in an ionic liquid.¹⁷⁴ A variation in the reaction used NBS with 5% Yb(OTf)₃ and 5% ClSiMe₃.¹⁷⁵ Other *N*-bromo amides have also been used. Allylic chlorination has been carried out, with *N*-chlorosuccinimide, *tert*-butyl hypochlorite,¹⁷⁶ or with NaClO/CeCl₃·7 H₂O.¹⁷⁷ With any reagent an initiator is needed; this is usually AIBN (**1**), a peroxide, such as di-*tert*-butyl peroxide or benzoyl peroxide or, less often, UV light.

The reaction is usually quite specific at an allylic or benzylic position and good yields are obtained. However, when the allylic radical intermediate is unsymmetrical, allylic rearrangements can take place, so that mixtures of both possible products are obtained, **21** and **22**.

When a double bond has two different allylic positions (e.g., CH₃CH=CHCH₂CH₃), a secondary position is substituted more readily than a primary. The relative reactivity of tertiary hydrogen is not clear, though many substitutions at allylic tertiary positions have been performed.¹⁷⁸ It is possible to brominate both sides of the double bond.¹⁷⁹ Because of the electron-withdrawing nature of bromine, the second bromine substitutes on the other side of the double bond rather than α to the first bromine. Molecules with a benzylic hydrogen, such as toluene, react rapidly to give α -bromomethyl benzene (e.g., PhCH₃ \rightarrow PhCH₂Br).

N-Bromosuccinimide is also a highly regioselective brominating agent at other positions, including positions α to a carbonyl group, to a C \equiv C triple bond, and to an aromatic ring (benzylic position). When both a double and a triple bond are in the same molecule, the preferred position is α to the triple bond.¹⁸⁰

Dauben and McCoy demonstrated that the mechanism of allylic bromination is of the free-radical type,¹⁸¹ showing that the reaction is very sensitive to free-radical

initiators and inhibitors and indeed does not proceed at all unless at least a trace of initiator is present. Subsequent work indicated that the species that actually abstracts hydrogen from the substrate is the bromine atom. The reaction is initiated by small amounts of $\text{Br}\cdot$. Once it is formed, the main propagation steps are

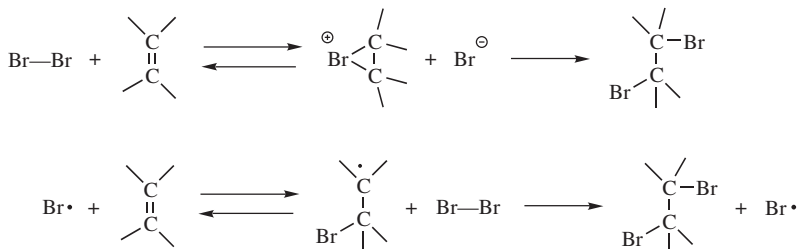

The source of the Br_2 is a fast ionic reaction between NBS and the HBr liberated in step 1:

The function of the NBS is therefore to provide a source of Br_2 in a low, steady-state concentration and to use up the HBr liberated in step 1.¹⁸² The main evidence for this mechanism is that NBS and Br_2 show similar selectivity¹⁸³ and that the various *N*-bromo amides also show similar selectivity,¹⁸⁴ which is consistent with the hypothesis that the same species is abstracting in each case.¹⁸⁵

It may be asked why, if Br_2 is the reacting species, it does not add to the double bond, either by an ionic or by a free-radical mechanism (see **15-39**). Apparently the concentration is too low. In bromination of a double bond, only one atom of an attacking bromine molecule becomes attached to the substrate, whether the addition is electrophilic or free radical:

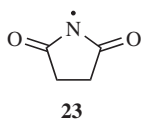

¹⁸²This mechanism was originally suggested by Adam, J.; Gosselain, P.A.; Goldfinger, P. *Nature (London)*, **1953**, 171, 704; *Bull. Soc. Chim. Belg.* **1956**, 65, 533.

¹⁸⁴Walling, C.; Rieger, A.L. *J. Am. Chem. Soc.* **1963**, 85, 3134; Pearson, R.; Martin, J.C. *J. Am. Chem. Soc.* **1963**, 85, 3142; Incremona, J.H.; Martin, J.C. *J. Am. Chem. Soc.* **1970**, 92, 627.

¹⁸⁵For other evidence, see Day, J.C.; Lindstrom, M.J.; Skell, P.S. *J. Am. Chem. Soc.* **1974**, 96, 5616.

The other bromine atom comes from another bromine-containing molecule or ion. This is clearly not a problem in reactions with benzylic species since the benzene ring is not prone to such addition reactions. If the concentration is sufficiently low, there is a low probability that the proper species will be in the vicinity once the intermediate forms. The intermediate in either case reverts to the initial species and the allylic substitution competes successfully. If this is true, it should be possible to brominate an alkene in the allylic position without competition from addition, even in the absence of NBS or a similar compound, if a very low concentration of bromine is used and if the HBr is removed as it is formed so that it is not available to complete the addition step. This has indeed been demonstrated.¹⁸⁶

When NBS is used to brominate non-alkenyl substrates, such as alkanes, another mechanism, involving abstraction of the hydrogen of the substrate by the succinimidyl radical¹⁸⁷ **23** can operate.¹⁸⁸ This mechanism is facilitated by solvents (e.g., CH₂Cl₂, CHCl₃, or MeCN) in which NBS is more soluble, and by the presence of small amounts of an alkene that lacks an allylic hydrogen (e.g., ethene). The alkene serves to scavenge any Br• that forms from the reagent. Among the evidence for the mechanism involving **23** are abstraction selectivities similar to those of Cl• atoms and the isolation of β-bromopropionyl isocyanate (BrCH₂CH₂CONCO) which is formed by ring opening of **23**.

Allylic chlorination has also been carried out¹⁸⁹ with *N*-chlorosuccinimide (NCS) and either arylselenyl chlorides (ArSeCl), aryl diselenides (ArSeSeAr), or TsNSO as catalysts. Use of the selenium catalysts produces almost entirely the allylically rearranged chlorides in high yields. With TsNSO the products are the unrearranged chlorides in lower yields. Dichlorine monoxide Cl₂O, with no catalyst, also gives allylically rearranged chlorides in high yields.¹⁹⁰ A free-radical mechanism is unlikely in these reactions.

Allyl silanes react with transition metals bearing chlorine ligands to give allyl chlorides, where a chlorine replaces a Me₃Si unit.¹⁹¹

14-4 Halogenation of Aldehydes**Halogenation or Halo-de-hydrogenation**

The α -halogenation reaction of carbonyl compounds was mentioned in Section 14-2. A different halogenation reaction is possible in which aldehydes can be directly converted to acyl chlorides by treatment with chlorine, but the reaction operates only when the aldehyde does not contain an α hydrogen and even then it is not very useful. When there is an α hydrogen, α halogenation (14-2, 12-4) occurs instead. Other sources of chlorine have also been used, among them SO_2Cl_2 ¹⁹² and *t*-BOCl.¹⁹³ The mechanisms are probably of the free-radical type. *N*-Bromosuccinimide, with AIBN (p. 935) as a catalyst, has been used to convert aldehydes to acyl bromides.¹⁹⁴

14-6 Formation of Cyclic Ethers

(5)OC-cyclo-Alkoxy-de-hydro-substitution

Alcohols with a hydrogen in the δ position can be cyclized with lead tetraacetate.²⁰⁶ The reaction is usually carried out at $\sim 80^\circ\text{C}$ (most often in refluxing benzene), but can also be done at room temperature if the reaction mixture is irradiated with uv light. Tetrahydrofurans are formed in high yields. Little or no four- and six-membered cyclic ethers (oxetanes and tetrahydropyrans, respectively) are obtained even when γ and ϵ hydrogens are present. The reaction has also been carried out with a mixture of halogen (Br₂ or I₂) and a salt or oxide of silver or mercury (especially HgO or AgOAc),²⁰⁷ with iodosobenzene diacetate and I₂,²⁰⁸ and with ceric

ammonium nitrate (CAN).²⁰⁹ The following mechanism is likely for the lead tetraacetate reaction:²¹⁰

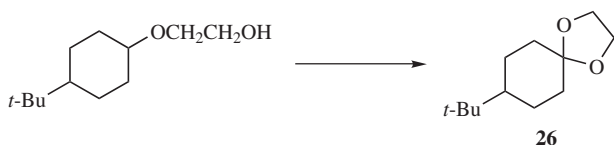

though **24** has never been isolated. The step marked **A** is a 1,5 internal hydrogen abstraction. Such abstractions are well known (see **18-40**) and are greatly favored over 1,4 or 1,6 abstractions (the small amounts of tetrahydropyran formed result from 1,6 abstractions).²¹¹

Reactions that sometimes compete are oxidation to the aldehyde or acid (**19-3** and **19-22**) and fragmentation of the substrate. When the OH group is on a ring of at least seven members, a transannular product can be formed, as in the cyclization reaction of 1-octanol to **25**.²¹²

β -Hydroxy ethers can give cyclic acetals, such as **26**.²¹³

14-7 Formation of Hydroperoxides

Hydroperoxy-de-hydrogenation

The slow atmospheric oxidation (*slow* meaning without combustion) of C—H to C—O—O—H is called *autoxidation*.²¹⁴ The reaction occurs when compounds are allowed to stand in air and is catalyzed by light, so unwanted autoxidations can be greatly slowed by keeping the compounds in dark places. Most autoxidations proceed by free-radical chain processes that involve peroxy radicals.²¹⁵ To suppress autoxidation, an antioxidant can be added that will prevent or retard the reaction with atmospheric oxygen.²¹⁶ Although some lactone compounds are sold as antioxidants, many radicals derived from lactones show poor or no reactivity toward oxygen.²¹⁶ The hydroperoxides produced often react further to give alcohols, ketones, and more complicated products, so the reaction is not often used for preparative purposes, although in some cases hydroperoxides have been prepared in good yield.²¹⁷ It is because of autoxidation that foods, rubber, paint, lubricating oils, and so on deteriorate on exposure to the atmosphere over periods of time. On the other hand, a useful application of autoxidation is the atmospheric drying of paints and varnishes. As with other free-radical reactions of C—H bonds, some bonds are attacked more readily than others,²¹⁸ and these are the ones we have seen before (pp. 943–949), though the selectivity is very low at high temperatures and in the gas phase. The reaction can be carried out successfully at tertiary (to a lesser extent, secondary), benzylic,²¹⁹ and allylic (though allylic rearrangements are common) R.²²⁰ 2-Phenylpropane reacted with oxygen to give PhMe₂C—OOH, for example. Another susceptible position is aldehydic C—H,

²¹⁴The term autoxidation actually applies to any slow oxidation with atmospheric oxygen. See Goosen, A.; Morgan, D.H. *J. Chem. Soc. Perkin Trans. 2* **1994**, 557. but the peroxyacids so produced are not easily isolated²²¹ since they are converted to the corresponding carboxylic acids (**19-23**). The α positions of ethers are also easily attacked by oxygen [RO-C-H \rightarrow RO-C-OOH], but the resulting hydroperoxides are seldom isolated. However, this reaction constitutes a hazard in the storage of ethers since solutions of these hydroperoxides and their rearrangement products in ethers are potential spontaneous explosives.²²²

Oxygen itself (a diradical) is not reactive enough to be the species that actually abstracts the hydrogen. But if a trace of free radical (say R'•) is produced by some initiating process, it reacts with oxygen²²³ to give R'-O-O•; since this type of radical *does* abstract hydrogen, the chain is

In at least some cases (in alkaline media)²²⁴ the radical R• can be produced by formation of a carbanion and its oxidation (by O₂) to a radical, such as allylic radical **27**.²²⁵

Autoxidations in alkaline media can also proceed by a different mechanism: R-H + base \rightarrow R⁻ + O₂ \rightarrow ROO⁻.²²⁶

When alkenes are treated with oxygen that has been photosensitized (p. 341), they are substituted by OOH in the allylic position in a synthetically useful reaction.²²⁷ Although superficially similar to autoxidation, this reaction is clearly different because 100% allylic rearrangement always takes place. The reagent here is not

the ground-state oxygen (a triplet), but an excited singlet state²²⁸ (in which all electrons are paired), and the function of the photosensitization is to promote the oxygen to this singlet state. Singlet oxygen can also be produced by nonphotochemical means,²²⁹ for example, by the reaction between H_2O_2 and NaOCl ²³⁰ or sodium molybdate,²³¹ or between ozone and triphenyl phosphite.²³² Calcium peroxide diperoxohydrate ($\text{CaO}_2 \cdot 2\text{H}_2\text{O}_2$) has been reported as a storable compound used for the chemical generation of singlet oxygen.²³³ The oxygen generated by either photochemical or nonphotochemical methods reacts with alkenes in the same way;²³⁴ this is evidence that singlet oxygen is the reacting species in the photochemical reaction and not some hypothetical complex between triplet oxygen and the photosensitizer, as had previously been suggested. The fact that 100% allylic rearrangement always takes place is incompatible with a free-radical mechanism, and

further evidence that free radicals are not involved comes from the treatment of optically active limonene (**28**) with singlet oxygen. Among other products is the optically active hydroperoxide **29**, though if **30** were an intermediate, it could not give an optically active product since it possesses a plane of symmetry.²³⁵ In contrast, autoxidation of **28** gave optically inactive **29** (a mixture of four diastereomers in which the two pairs of enantiomers are present as racemic mixtures). As this example shows, singlet oxygen reacts faster with more-highly substituted than with less-highly substituted alkenes. The order of alkene reactivity is

tetrasubstituted > trisubstituted > disubstituted. Electron-withdrawing substituents deactivate the alkene.²³⁶ In simple trisubstituted alkenes, there is a general preference for the hydrogen to be removed from the more highly congested side of the double bond.²³⁷ With *cis*-alkenes of the form RCH=CHR', the hydrogen is removed from the larger R group.²³⁸ Many functional groups in an allylic position cause the hydrogen to be removed from that side rather than the other (geminal selectivity).²³⁹ Also, in alkyl-substituted alkenes, the hydrogen that is preferentially removed is the one geminal to the larger substituent on the double bond.²⁴⁰

Several mechanisms have been proposed for the reaction with singlet oxygen.²⁴¹ One of these is a pericyclic mechanism, similar to that of the ene synthesis (**15-23**) and to the first step of the reaction between alkenes and SeO₂ (**19-14**). However, there is strong evidence against this mechanism,²⁴² and a more likely mechanism involves addition of singlet oxygen to the double bond to give a perepoxide (**31**),²⁴³ followed by internal proton transfer.²⁴⁴

Still other proposed mechanisms involve diradicals or dipolar intermediates.²⁴⁵

14-8 Formation of Peroxides

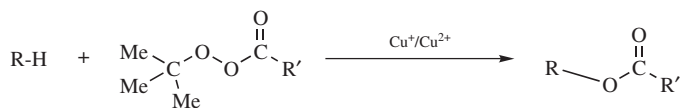

Alkyldioxy-de-hydrogenation

Peroxy groups (ROO) can be introduced into susceptible organic molecules by treatment with a hydroperoxide in the presence of cuprous chloride or other catalysts, for example, cobalt and manganese salts.²⁴⁶ Very high yields can be obtained. The type of hydrogen replaced is similar to that with NBS (**14-3**), that is, mainly benzylic, allylic, and tertiary. The mechanism is therefore of the free-radical type, involving ROO• formed from ROOH and the metal ion. The reaction can be used to demethylate tertiary amines of the form R₂NCH₃, since the product R₂NHCH₂OOR' can easily be hydrolyzed by acid (**10-6**) to give R₂NH.²⁴⁷

14-9 Acyloxylation

Acyloxylation or Acyloxy-de-hydrogenation

Susceptible positions of organic compounds can be directly acyloxyated²⁴⁸ by *tert*-butyl peroxyesters, the most frequently used being acetic and benzoic (R' = Me or Ph).²⁴⁹ The reaction requires a catalyst (cuprous ion is the actual catalyst, but a trace is all that is necessary, and such traces are usually present in cupric compounds, so that these are often used) and without it is not selective. Susceptible positions are similar to those in **14-6**: benzylic, allylic, and the a position of ethers and sulfides. Terminal alkenes are substituted almost entirely in the 3 position, that is, with only a small amount of allylic rearrangement, but internal alkenes generally give mixtures containing a large amount of allylic-shift product. If the reaction with alkenes is carried out in an excess of

another acid $R''\text{COOH}$, the ester produced is of *that* acid ROCOR'' . Aldehydes give anhydrides:

Acyloxylation has also been achieved with metallic acetates, such as lead tetraacetate,²⁵⁰ mercuric acetate,²⁵¹ and palladium(II) acetate.²⁵² In the case of the lead and mercuric acetates, not only does the reaction take place at allylic and benzylic positions and at those α to an OR or SR group, but also at positions α to the carbonyl groups of aldehydes, ketones, or esters and at those α to two carbonyl groups ($\text{ZCH}_2\text{Z}'$). It is likely that in the latter cases it is the enol forms that react. Ketones can be α -acyloxylation indirectly by treatment of various enol derivatives with metallic acetates, for example, silyl enol ethers with silver carboxylates-iodine,²⁵³ enol thioethers with lead tetraacetate,²⁵⁴ and enamines²⁵⁵ with lead tetraacetate²⁵⁶ or thallium triacetate.²⁵⁷ α,β -Unsaturated ketones can be acyloxylation in good yields in the α' position with manganese triacetate.²⁵⁸ Palladium acetate converts alkenes to vinylic and/or allylic acetates.²⁵⁹ Lead tetraacetate even acyloxylation alkanes, in a slow reaction (10 days to 2 weeks), with tertiary and secondary positions greatly favored over primary ones.²⁶⁰ Yields are as high as 50%. Acyloxylation of certain alkanes has also been reported with palladium(II) acetate.²⁶¹

²⁶¹This was done in trifluoroacetic acid, and the products were trifluoroacetates: Sen, A.; Gretz, E.; Oliver, T.F.; Jiang, Z. *New J. Chem.* **1989**, *13*, 755.

Studies of the mechanism of the cuprous-catalyzed reaction show that the most common mechanism is the following:²⁶²

This mechanism, involving a free radical $\text{R}\cdot$, is compatible with the allylic rearrangements found.²⁶³ The finding that *tert*-butyl peroxyesters labeled with ^{18}O in the carbonyl oxygen gave ester with 50% of the label in each oxygen²⁶⁴ is in accord with a combination of $\text{R}\cdot$ with the intermediate **32**, in which the copper is ionically bound, so that the oxygens are essentially equivalent. Other evidence is that *tert*-butoxy radicals have been trapped with dienes.²⁶⁵ Much less is known about the mechanisms of the reactions with metal acetates.²⁶⁶

Free-radical acyloxylation of aromatic substrates²⁶⁷ has been accomplished with a number of reagents including copper(II) acetate,²⁶⁸ benzoyl peroxide-iodine,²⁶⁹ silver(II) complexes,²⁷⁰ and cobalt(III) trifluoroacetate.²⁷¹

The chlorosulfonation of organic molecules with chlorine and sulfur dioxide is called the *Reed reaction*.²⁷² In scope and range of products obtained, the reaction is similar to **14-1**. The mechanism is also similar, except that there are two additional main propagation steps:

*Chlorosulfenation*²⁷³ can be accomplished by treatment with SOCl_2 and UV light: $\text{RH} + \text{SOCl}_2 \xrightarrow{h\nu} \text{RSOCl}$.

D. Substitution by Nitrogen

14-11 The Direct Conversion of Aldehydes to Amides

Amination or Amino-de-hydrogenation

Aliphatic and aromatic aldehydes have been converted to the corresponding amides with ammonia or a primary or secondary amine, NBS, and a catalytic amount of AIBN (p. 935).²⁷⁴ In a reaction of more limited scope, amides are obtained from aromatic and α,β -unsaturated aldehydes by treatment with dry ammonia gas and nickel peroxide.²⁷⁵ Best yields (80–90%) are obtained at -25 to -20°C . In the nickel peroxide reaction the corresponding alcohols (ArCH_2OH) have also been used as substrates.

The reaction has also been performed with MnO_2 and NaCN along with ammonia or an amine at 0°C in isopropyl alcohol.²⁷⁶ Aldehydes were also shown to react with hydroxylamine hydrochloride at 140°C in the presence of aluminum oxide and methanesulfonic acid.²⁷⁷ Treatment of an aldehyde with iodine in aqueous ammonia, followed by oxidation with aqueous hydrogen peroxide generates a primary amide.²⁷⁸ Secondary amines react with aldehydes to form an amide in using a palladium catalyst²⁷⁹ or a rhodium catalyst.²⁸⁰ For an indirect way of converting aldehydes to amides, see **12-32**. Thioamides RCSNR'_2 have been prepared in good yield

from thioaldehydes (produced *in situ* from phosphoranes and sulfur) and secondary amines.²⁸¹

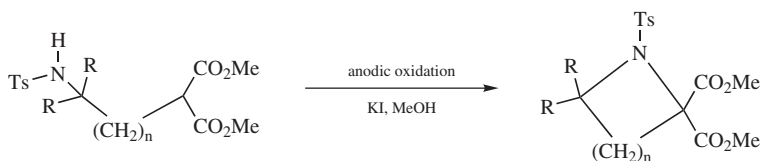

14-12 Amidation and Amination at an Alkyl Carbon

Acylamino-de-hydrogenation

When alkanes bearing a tertiary hydrogen are exposed to UV light in acetonitrile containing a heteropolytungstic acid, they are amidated.²⁸² The oxygen in the product comes from the tungstic acid. When the substrate bears two adjacent tertiary hydrogens, alkenes are formed (by loss of two hydrogens), rather than amides (**19-2**). Amidyl radicals can be generated by other means.²⁸³

An electrochemical method for amination has been reported by Shono and co-workers.²⁸⁴ Derivatives of malonic esters containing an *N*-tosyl group were cyclized in high yields by anodic oxidation:

Three-, four-, and five-membered rings were synthesized by this procedure.

14-13 Substitution by Nitro

Nitro-de-carboxylation

In a reaction termed a “nitro-Hunsdiecker” (see **14-30**), vinyl carboxylic acids (conjugated acids) are treated with nitric acid and a catalytic amount of AIBN (p. 935). The product is the vinyl nitro compound, generated via decarboxylation of a radical intermediate.²⁸⁵

E. Substitution by Carbon

In these reactions, a new carbon-carbon bond is formed and they may be given the collective title *coupling reactions*. In each case, an alkyl or aryl radical is generated and then combines with another radical (a termination process) or attacks an aromatic ring or alkene to give the coupling product.²⁸⁶

14-14 Simple Coupling at a Susceptible Position

De-hydrogen-coupling

Alkane and alkyl substrates RH are treated with peroxides, which decompose to give a radical that abstracts a hydrogen from RH to give R•, which dimerizes. Dialkyl and diacyl peroxides have been used, as well as Fenton's reagent (p. 964). This reaction is far from general, though in certain cases respectable yields have been obtained. Among susceptible positions are those at a tertiary carbon,²⁸⁷ as well as those α to a phenyl group (especially if there is also an α -alkyl or α -chloro group),²⁸⁸ an ether group,²⁸⁹ a carbonyl group,²⁹⁰ a cyano group,²⁹¹ a dialkylamino group,²⁹² or a carboxylic ester group, either the acid or alcohol side.²⁹³ Cross-coupling is possible in some cases. When toluene was heated with allyl bromide, in the presence of di-*tert*-butyl peroxide, 4-phenyl-1-butene was formed quantitatively.²⁹⁴

Conjugated amide were coupled via the γ -carbon to give good yields of the dimeric diamide, with an excess of samarium (II) iodide, and with modest enantioselectivity using a chiral additive.²⁹⁵

Alkanes can be dimerized by vapor-phase mercury photosensitization²⁹⁶ in a synthetically useful process. Best results are obtained for coupling at tertiary positions, but compounds lacking tertiary hydrogens (e.g., cyclohexane) also give good yields. Dimerization of *n*-alkanes gives secondary-secondary coupling in a nearly statistical distribution, with primary positions essentially unaffected. Alcohols and ethers dimerize at the position α to the oxygen [e.g., 2 EtOH \rightarrow MeCH(OH)CH(OH)Me].

When a mixture of compounds is treated, cross-dimerization (to give **33**) and homodimerization take place statistically.

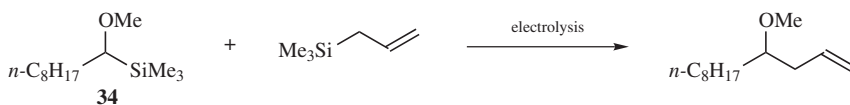

Even with the limitation on yield implied by the statistical process, cross-dimerization is still useful when one of the reactants is an alkane, because the products are easy to separate, and because of the few other ways to functionalize an alkane. The cross-coupling of an alkane with trioxane is especially valuable, because hydrolysis of the product (**10-6**) gives an aldehyde, thus achieving the conversion $\text{RH} \rightarrow \text{RCHO}$. The mechanism probably involves abstraction of H by the excited Hg atom, and coupling of the resulting radicals.

The reaction has been extended to ketones, carboxylic acids and esters (all of which couple α to the C=O group), and amides (which couple α to the nitrogen) by running it in the presence of H_2 .²⁹⁷ Under these conditions it is likely that the excited Hg abstracts $\text{H}\cdot$ from H_2 , and that the remaining $\text{H}\cdot$ abstracts H from the substrate. Radicals have also been generated at benzylic positions and shown to couple with epoxides, forming an alcohol.²⁹⁸

OS IV, 367; V, 1026; VII, 482.

14-15 Coupling at a Susceptible Position Via Silanes

De-silyl-coupling

Under electrochemical conditions it is possible to couple two silanes. The reaction of **34** and allyltrimethylsilane, for example, gave the corresponding homoallylic ether.²⁹⁹

14-16 Coupling of Alkynes³⁰⁰

De-hydrogen-coupling

Terminal alkynes can be coupled by heating with stoichiometric amounts of cupric salts in pyridine or a similar base. This reaction, which produces symmetrical diynes in high yields, is called the *Eglinton reaction*.³⁰¹ The large-ring annulenes of Sondheimer et al. (see p. 71) were prepared by rearrangement and hydrogenation of cyclic polyynes,³⁰² prepared by the Eglinton reaction with terminal diynes to give **35**, a cyclic trimer of 1,5-hexadiyne.³⁰³ The corresponding tetramers (C₂₄), pentamers (C₃₀), and hexamers (C₃₆) were also formed. The Eglinton reaction is of wide scope. Many functional groups can be present on the alkyne. The oxidation is usually quite specific for triple-bond hydrogen.

Another common procedure is the use of catalytic amounts of cuprous salts in the presence of ammonia or ammonium chloride (this method is called the *Glaser reaction*). Atmospheric oxygen or some other oxidizing agent, such as permanganate or hydrogen peroxide is required in the latter procedure. This method is not satisfactory for cyclic coupling. Hydrogen peroxide, potassium permanganate, potassium ferricyanide, iodine or Cu(II) can be used instead of oxygen as oxidants.³⁰⁴ Isolation of copper acetylide during the reaction can be avoided by doing the reaction in pyridine or cyclohexylamine, in the presence of catalytic amount of

CuCl_3 .³⁰⁵ If the Glaser reaction is done with a N,N,N',N' -tetramethylethylenediamine– CuCl complex, the reaction proceeds in good yield in virtually any organic solvent.³⁰⁶ When molecular oxygen is the oxidant, this modification of Glaser condensation is known as the *Hay reaction*. A variation couples terminal alkynes using CuCl_2 in supercritical CO_2 (see p. 414),³⁰⁷ and in ionic liquids.³⁰⁸ Coupling was also achieved using CuCl_2 on $\text{KF–Al}_2\text{O}_3$ with microwave irradiation.³⁰⁹ Homocoupling of alkynyl amines $\text{R}_2\text{N–C}\equiv\text{CH}$ to give the diyne $\text{R}_2\text{N–C}\equiv\text{C–C}\equiv\text{C–NR}_2$ was reported in aerated acetone with 10% CuI and 20% TMEDA.³¹⁰

Unsymmetrical diynes can be prepared by *Cadiot–Chodkiewicz* coupling:³¹¹

This may be regarded as a variation of **10-74**, but it must have a different mechanism since acetylenic halides give the reaction but ordinary alkyl halides do not, which is hardly compatible with a nucleophilic mechanism. However, the mechanism is not fully understood. One version of this reaction binds the alkynyl bromide unit to a polymer, and the di-yne is released from the polymer after the solid state transformation.³¹² Alkynes have also been coupled using CuI and a palladium catalyst.³¹³ Propargyl halides also give the reaction,³¹⁴ as do 1-bromo propargylic alcohols ($\text{Br–C}\equiv\text{C–CH}_2\text{OH}$).³¹⁵ A variation of the Cadiot–Chodkiewicz method consists of treating a haloalkyne ($\text{R}'\text{C}\equiv\text{CX}$) with a copper acetylide ($\text{RC}\equiv\text{CCu}$).³¹⁶ The Cadiot–Chodkiewicz procedure can be adapted to the preparation of diynes in which $\text{R}' = \text{H}$ by the use of $\text{BrC}\equiv\text{CSiEt}_3$ and subsequent cleavage of the SiEt_3 group.³¹⁷ This protecting group can also be used in the Eglinton or Glaser methods.³¹⁸

The mechanism of the Eglinton and Glaser reactions probably begins with loss of a proton

since there is a base present and acetylenic protons are acidic. It is known, of course, that cuprous ion can form complexes with triple bonds. The last step is probably the coupling of two radicals:

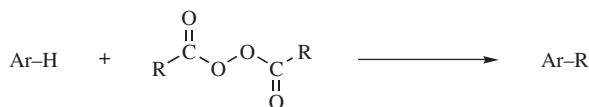

but just how the carbanion becomes oxidized to the radical and what part the cuprous ion plays (other than forming the acetylide salt) are matters of considerable speculation,³¹⁹ and depend on the oxidizing agent. One proposed mechanism postulated Cu(II) as the oxidant.³²⁰ It has been shown that molecular oxygen forms adducts with Cu(I) supported by tertiary amines, which might be the intermediates in the Glaser reaction where molecular oxygen is the oxidant.³²¹ For the Hay reaction, the mechanism involves a Cu^I/Cu^{III}/Cu^{II}/Cu^I catalytic cycle, and the key step for this reaction is the dioxygen activation during complexation of two molecules of acetylide with molecular oxygen, giving a Cu(III) complex.³²² This mechanism is supported by isolation and characterization of Cu(III) complexes formed under the conditions of the Glaser coupling.

Terminal alkynes are not the only reaction partners. 1-Trimethylsilyl alkynes (R-C≡C-SiMe₃) give the diyne R-C≡C-C≡C-R upon reaction with CuCl³²³ or Cu(OAc)₂/Bu₄NF.³²⁴

14-17 Alkylation and Arylation of Aromatic Compounds by Peroxides

Alkylation or Alkyl-de-hydrogenation

This reaction is most often carried out with R = aryl, so the net result is the same as in **13-27**, though the reagent is different.³²⁵ It is used less often than **13-27**, but

³¹⁹See the discussions, in Nigh, W.G., in Trahanovsky, W.S. *Oxidation in Organic Chemistry*, pt. B, Academic Press, NY, **1973**, pp. 27–31; Fedenok, L.G.; Berdnikov, V.M.; Shvartsberg, M.S. *J. Org. Chem. USSR* **1973**, 9, 1806; Clifford, A.A.; Waters, W.A. *J. Chem. Soc.* **1963**, 3056.

³²⁵For reviews, see Bolton, R.; Williams, G.H. *Chem. Soc. Rev.* **1986**, 15, 261; Hey, D.H. *Adv. Free-Radical Chem.* **1966**, 2, 47.

the scope is similar. When R = alkyl, the scope is more limited.³²⁶ Only certain aromatic compounds, particularly benzene rings with two or more nitro groups, and fused ring systems, can be alkylated by this procedure. 1,4-Quinones can be alkylated with diacyl peroxides or with lead tetraacetate (methylation occurs with this reagent).

The mechanism is as shown on p. 940 (CIDNP has been observed³²⁷); the radicals are produced by

Since no relatively stable free radical is present (such as $\bullet\text{O}-\text{N}=\text{N}-\text{Ar}$ in **13-27**), most of the product arises from dimerization and disproportionation.³²⁸ The addition of a small amount of nitrobenzene increases the yield of arylation product because the nitrobenzene is converted to diphenyl nitroxide, which abstracts the hydrogen from **5** and reduces the extent of side reactions.³²⁹

Aromatic compounds can also be arylated by aryllead tricarboxylates.³³⁰ Best yields (~70–85%) are obtained when the substrate contains alkyl groups; an electrophilic mechanism is likely. Phenols are phenylated ortho to the OH group (and enols are a phenylated) by triphenylbismuth dichloride or by certain other Bi(V) reagents.³³¹ *O*-Phenylation is a possible side reaction. As with the aryllead tricarboxylate reactions, a free-radical mechanism is unlikely.³³²

³³²Barton, D.H.R.; Finet, J.; Giannotti, C.; Halley, F. *J. Chem. Soc. Perkin Trans. 1* **1987**, 241.

Another free-radical arylation method consists of the photolysis of aryl iodides in an aromatic solvent.³³³ Yields are generally higher than in **13-27** or **14-17**. The aryl iodide may contain OH or COOH groups. The coupling reaction of iodobenzene and azulene to give a phenylazulene was reported (41% conversion and 85% yield).³³⁴ The mechanism is similar to that of **13-27**. The aryl radicals are generated by the photolytic cleavage $\text{ArI} \rightarrow \text{AR}\cdot + \text{I}\cdot$. The reaction has been applied to intramolecular arylation (analogous to the Pschorr reaction).³³⁵ A similar reaction is photolysis of an arylthallium bis(trifluoroacetate) (**12-23**) in an aromatic solvent. Here too, an unsymmetrical biaryl is produced in good yields.³³⁶ In this case, it is the C—Tl bond that is cleaved to give aryl radicals.

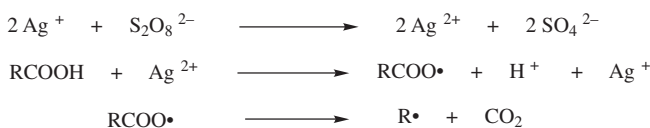

14-19 Alkylation, Acylation, and Carbalkoxylation of Nitrogen Heterocycles³³⁷

Alkylation or Alkyl-de-hydrogenation, and so on

Alkylation of protonated nitrogen heterocycles (e.g., pyridines, quinolines) can be accomplished by treatment with a carboxylic acid, silver nitrate, sulfuric acid, and ammonium peroxydisulfate.³³⁸ The R group can be primary, secondary, or tertiary. The attacking species is $\text{R}\cdot$, formed by³³⁹

³³⁹Anderson, J.M.; Kochi, J.K. *J. Am. Chem. Soc.* **1970**, *92*, 1651.

A hydroxymethyl group can be introduced ($\text{ArH} \rightarrow \text{ArCH}_2\text{OH}$) by several variations of this method.³⁴⁰ Alkylation of these substrates can also be accomplished by generating the alkyl radicals in other ways: from hydroperoxides and FeSO_4 ,³⁴¹ from alkyl iodides and $\text{H}_2\text{O}_2\text{-Fe(II)}$,³⁴² from carboxylic acids and lead tetraacetate, or from the photochemically induced decarboxylation of carboxylic acids by iodosobenzene diacetate.³⁴³

Protonated nitrogen heterocycles, such as quinoxaline (**36**), can be acylated by treatment with an aldehyde, *tert*-butyl hydroperoxide, sulfuric acid, and ferrous sulfate, in this case giving **37**.³⁴⁴

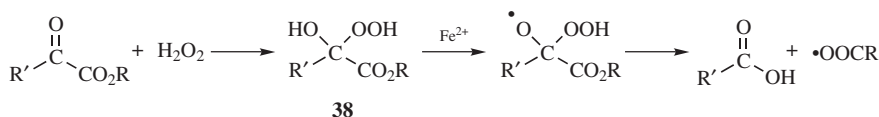

Photochemical alkylation of protonated quinoline occurred with $\text{Ph}_2\text{Se}(\text{O}_2\text{C}-\text{C}_6\text{H}_{11})_2$.³⁴⁵

Other positively charged heterocycles react as well. When *N*-fluoropyridinium triflate was treated with the enolate anion of acetone, 2-(2-oxopropyl)pyridine was formed in modest yield.³⁴⁶

These alkylation and acylation reactions are important because Friedel–Crafts alkylation and acylation (**11-11**, **11-17**) cannot be applied to most nitrogen heterocycles (see also **13-17**).

Protonated nitrogen heterocycles can be carbalkoxylated³⁴⁷ by treatment with esters of α -keto acids and Fenton's reagent. Pyridine is carbalkoxylated at C-2 and C-4, for example. The attack is by $\bullet\text{COOR}$ radicals generated from the esters via a hydroperoxide (**38**).

³⁴⁰See Citterio, A.; Gentile, A.; Minisci, F.; Serravalle, M.; Ventura, S. *Tetrahedron* **1985**, *41*, 617; Katz, R.B.; Mistry, J.; Mitchell, M.B. *Synth. Commun.* **1989**, *19*, 317.

Similarly, a carbamoyl group can be introduced³⁴⁸ by the use of the radicals $\text{H}_2\text{N}-\overset{\text{O}}{\parallel}{\text{C}}\cdot$ or $\text{Me}_2\text{N}-\overset{\text{O}}{\parallel}{\text{C}}\cdot$ generated from formamide or DMF and H_2SO_4 , H_2O_2 , and FeSO_4 or other oxidants.

N₂ AS LEAVING GROUP³⁴⁹

In these reactions diazonium salts are cleaved to aryl radicals,³⁵⁰ in most cases with the assistance of copper salts. Reactions **13-27** and **13-26** may also be regarded as belonging to this category with respect to the attacking compound. For nucleophilic substitutions of diazonium salts (see **13-20–13-23**). Removal of nitrogen and replacement with a hydrogen atom is a reduction, found in Chapter 19.

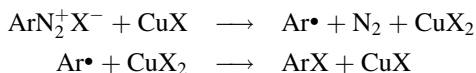

14-20 Replacement of the Diazonium Group by Chlorine or Bromine

Chloro-de-diazoniation, and so on

Treatment of diazonium salts with cuprous chloride or bromide leads to aryl chlorides or bromides, respectively. In either case, the reaction is called the *Sandmeyer reaction*.³⁵¹ The reaction can also be carried out with copper and HBr or HCl, in which case it is called the *Gatterman reaction* (not to be confused with **11-18**). The Sandmeyer reaction is not useful for the preparation of fluorides or iodides, but for bromides and chlorides it is of wide scope and is probably the best way of introducing bromine or chlorine into an aromatic ring. The yields are usually high.

The mechanism is not known with certainty, but is believed to take the following course:³⁵²

³⁵¹Rate constants for this reaction have been determined. See Hanson, P.; Hammond, R.C.; Goodacre, P.R.; Purcell, J.; Timms, A.W. *J. Chem. Soc. Perkin Trans. 2* **1994**, 691.

³⁵²Dickerman, S.C.; Weiss, K.; Ingberman, A.K. *J. Am. Chem. Soc.* **1958**, *80*, 1904; Kochi, J.K. *J. Am. Chem. Soc.* **1957**, *79*, 2942; Dickerman, S.C.; DeSouza, D.J.; Jacobson, N. *J. Org. Chem.* **1969**, *34*, 710; Galli, C. *J. Chem. Soc. Perkin Trans. 2* **1981**, 1459; **1982**, 1139; **1984**, 897. See also, Hanson, P.; Jones, J.R.; Gilbert, B.C.; Timms, A.W. *J. Chem. Soc. Perkin Trans. 2* **1991**, 1009.

The first step involves a reduction of the diazonium ion by the cuprous ion, which results in the formation of an aryl radical. In the second step, the aryl radical abstracts halogen from cupric chloride, reducing it. The CuX is regenerated and is thus a true catalyst.

Aryl bromides and chlorides can be prepared from primary aromatic amines in one step by several procedures,³⁵³ including treatment of the amine (1) with *tert*-butyl nitrite and anhydrous CuCl₂ or CuBr₂ at 65°C,³⁵⁴ and (2) with *tert*-butyl thionitrite or *tert*-butyl thionitrate and CuCl₂ or CuBr₂ at room temperature.³⁵⁵ These procedures are, in effect, a combination of **13-19** and the Sandmeyer reaction. A further advantage is that cooling to 0°C is not needed. A mixture of Me₃SiCl and NaNO₂ was used to convert aniline to chlorobenzene in a related reaction.³⁵⁶

For the preparation of fluorides and iodides from diazonium salts (see **13-32** and **13-31**).

It is noted that the reaction of aryl diazonium salts with CuCN to give benzonitrile derivatives is also called the *Sandmeyer reaction*. It is usually conducted in neutral solution to avoid liberation of HCN.

OS **I**, 135, 136, 162, 170; **II**, 130; **III**, 185; **IV**, 160. Also see, OS **III**, 136; **IV**, 182. For the reaction with CuCN, see OS **I**, 514.

14-21 Replacement of the Diazonium Group by Nitro

Nitro-de-diazonation

Nitro compounds can be formed in good yields by treatment of diazonium salts with sodium nitrite in the presence of cuprous ion. The reaction occurs only in neutral or alkaline solution. This is not usually called the Sandmeyer reaction, although, like **14-20**, it was discovered by Sandmeyer. Tetrafluoroborate (BF₄⁻) is often used as the negative ion since the diminished nucleophilicity avoids competition from the chloride ion. The mechanism is probably like that of **14-20**.³⁵⁷ If electron-withdrawing groups are present, the catalyst is not needed; NaNO₂ alone gives nitro compounds in high yields.³⁵⁸

³⁵³For other procedures, see Brackman, W.; Smit, P.J. *Recl. Trav. Chim. Pays-Bas*, **1966**, 85, 857; Cadogan, J.I.G.; Roy, D.A.; Smith, D.M. *J. Chem. Soc. C* **1966**, 1249.

An alternative procedure used electrolysis, in 60% HNO₃ to convert 1-amino-naphthalene to naphthalene.³⁵⁹

OS II, 225; III, 341.

14-22 Replacement of the Diazonium Group by Sulfur-Containing Groups

Chlorosulfo-de-diazoniatio

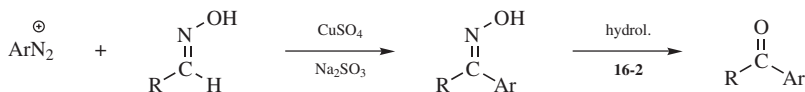

Diazonium salts can be converted to sulfonyl chlorides by treatment with sulfur dioxide in the presence of cupric chloride.³⁶⁰ The use of FeSO₄ and copper metal instead of CuCl₂ gives sulfonic acids (ArSO₂H)³⁶¹ (see also, **13-21**).

OS V, 60; VII, 508.

14-23 Conversion of Diazonium Salts to Aldehydes, Ketones, or Carboxylic Acids

Acyl-de-diazoniatio, and so on

Diazonium salts react with oximes to give aryl oximes, which are easily hydrolyzed to aldehydes (R = H) or ketones.³⁶² A copper sulfate-sodium sulfite catalyst is essential. In most cases higher yields (40–60%) are obtained when the reaction is used for aldehydes than for ketones. In another method³⁶³ for achieving the conversion ArN₂⁺ → ArCOR, diazonium salts are treated with R₄Sn and CO with palladium acetate as catalyst.³⁶⁴ In a different kind of reaction, silyl enol ethers of aryl ketones Ar'C(OSiMe₃)=CHR react with solid diazonium fluoroborates (ArN₂⁺BF₄⁻) to give ketones (ArCHRCOAr').³⁶⁵ This is, in effect, an arylation of the aryl ketone.

Carboxylic acids can be prepared in moderate-to-high yields by treatment of diazonium fluoroborates with carbon monoxide and palladium acetate³⁶⁶ or

copper(II) chloride.³⁶⁷ The mixed anhydride ArCOOCOMe is an intermediate that can be isolated. Other mixed anhydrides can be prepared by the use of other salts instead of sodium acetate.³⁶⁸ An arylpalladium compound is probably an intermediate.³⁶⁸

OS V, 139.

METALS AS LEAVING GROUPS

14-24 Coupling of Grignard Reagents

De-metallo-coupling

This organometallic coupling reaction is clearly related to the Wurtz coupling, discussed in **10-56**, and the coupling of other organometallic compounds is discussed in **14-25**. Grignard reagents can be coupled to give symmetrical dimers³⁶⁹ by treatment with either thallium(I) bromide³⁷⁰ or with a transition-metal halide, such as CrCl₂, CrCl₃, CoCl₂, CoBr₂, or CuCl₂.³⁷¹ The metallic halide is an oxidizing agent and becomes reduced. Both aryl and alkyl Grignard reagents can be dimerized by either procedure, though the TlBr method cannot be applied to R = primary alkyl or to aryl groups with ortho substituents. Aryl Grignard reagents can also be dimerized by treatment with 1,4-dichloro-2-butene, 1,4-dichloro-2-butyne, or 2,3-dichloropropene.³⁷² Vinylic and alkynyl Grignard reagents can be coupled (to give 1,3-dienes and 1,3-diyne, respectively) by treatment with thionyl chloride.³⁷³ Primary alkyl, vinylic, aryl, and benzylic Grignard reagents give symmetrical dimers in high yield (~90%) when treated with a silver(I) salt (e.g., AgNO₃, AgBr, AgClO₄) in the presence of a nitrogen-containing oxidizing agent, such as lithium nitrate, methyl nitrate, or NO₂.³⁷⁴ This method has been used to close rings of four, five, and six members.³⁷⁵

The mechanisms of the reactions with metal halides, at least in some cases, probably begin with conversion of RMgX to the corresponding RM (**12-36**), followed by its decomposition to free radicals.³⁷⁶

OS VI, 488.

14-25 Coupling of Other Organometallic Reagents³³²

De-metallo-coupling

Lithium dialkylcopper reagents can be oxidized to symmetrical dimers by O_2 at -78°C in THF.³⁷⁷ The reaction is successful for R = primary and secondary alkyl, vinylic, or aryl. Other oxidizing agents, for example, nitrobenzene, can be used instead of O_2 . Vinylic copper reagents dimerize on treatment with oxygen, or simply on standing at 0°C for several days or at 25°C for several hours, to yield 1,3-dienes.³⁷⁸ The finding of retention of configuration for this reaction demonstrates that free-radical intermediates are not involved.

The coupling reaction of Grignard reagents was discussed in **14-24**. Lithium organoaluminates (LiAlR_4) are dimerized to RR by treatment with $\text{Cu}(\text{OAc})_2$.³⁷⁹ Terminal vinylic alanes (prepared by **15-17**) can be dimerized to 1,3-dienes with CuCl in THF.³⁸⁰ Symmetrical 1,3-dienes can also be prepared in high yields by treatment of vinylic mercury chlorides³⁸¹ with LiCl and a rhodium catalyst³⁸² and by treatment of vinylic tin compounds with a palladium catalyst.³⁸³ Arylmercuric salts are converted to biaryls by treatment with copper and a catalytic amount of PdCl_2 .³⁸⁴ Vinylic, alkynyl, and aryl tin compounds were dimerized with

$\text{Cu}(\text{NO}_3)_2$.³⁸⁵ Alkyl- and aryllithium compounds can be dimerized by transition-metal halides in a reaction similar to **14-24**.³⁸⁶ Triarylbismuth compounds Ar_3Bi react with palladium(0) complexes to give biaryls ArAr .³⁸⁷ Diethylzinc reacted with $\text{Ph}_2\text{I}^+ \text{BF}_4^-$ in the presence of palladium acetate, to give biphenyl.³⁸⁸

Unsymmetrical coupling of vinylic, alkynyl, and arylmercury compounds was achieved in moderate-to-good yields by treatment with alkyl and vinylic dialkylcopper reagents, for example, $\text{PhCH}=\text{CHHgCl} + \text{Me}_2\text{CuLi} \rightarrow \text{PhCH}=\text{CHMe}$.³⁸⁹ Unsymmetrical biaryls were prepared by treating a cyanocuprate ($\text{ArCu}(\text{CN})\text{Li}$, prepared from ArLi and CuCN) with an aryllithium ($\text{Ar}'\text{Li}$).³⁹⁰

A radical coupling reaction has been reported, in which an aryl halide reacted with Bu_3SnH , AIBN, and benzene, followed by treatment with methyllithium to give the biaryl.³⁹¹

14-26 Coupling of Boranes

Alkyl-de-dialkylboration

Alkylboranes can be coupled by treatment with silver nitrate and base.³⁹² Since alkylboranes are easily prepared from alkenes (**15-16**), this is essentially a way of coupling and reducing alkenes; in fact, alkenes can be hydroborated and coupled in the same flask. For symmetrical coupling ($\text{R} = \text{R}'$) yields range from 60 to 80% for terminal alkenes and from 35 to 50% for internal ones. Unsymmetrical coupling has also been carried out,³⁹³ but with lower yields. Arylboranes react similarly, yielding biaryls.³⁹⁴ The mechanism is probably of the free-radical type.

Dimerization of two vinylborane units to give a conjugated diene can be achieved by treatment of divinylchloroboranes (prepared by addition of BH_2Cl to alkynes; see **15-16**) with methylcopper. (*E,E*)-1,3-Dienes are prepared in high

yields.³⁹⁵

In a similar reaction, symmetrical conjugated diynes $\text{RC}\equiv\text{C}-\text{C}\equiv\text{CR}$ can be prepared by reaction of lithium dialkyldialkynylborates, $\text{Li}^+ [\text{R}'_2\text{B}(\text{C}\equiv\text{CR})_2]^-$, with iodine.³⁹⁶

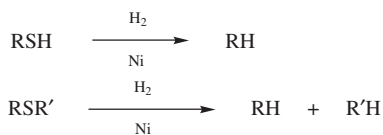

HALOGEN AS LEAVING GROUP

The conversion of RX to RH can occur by a free-radical mechanism but is treated at **19-53**.

SULFUR AS LEAVING GROUP

14-27 Desulfurization

Hydro-de-thio-substitution, and so on

Thiols and thioethers,³⁹⁷ both alkyl and aryl, can be desulfurized by hydrogenolysis with Raney nickel.³⁹⁸ The hydrogen is usually not applied externally, since Raney nickel already contains enough hydrogen for the reaction. Other sulfur compounds can be similarly desulfurized, among them disulfides (RSSR),

³⁹⁵Yamamoto, Y.; Yatagai, H.; Maruyama, K.; Sonoda, A.; Murahashi, S. *J. Am. Chem. Soc.* **1977**, *99*, 5652; *Bull. Chem. Soc. Jpn.* **1977**, *50*, 3427. thiono esters (RCSOR'),³⁹⁹ thioamides (RCDNHR'), sulfoxides, and dithioacetals. The last reaction, which is an indirect way of accomplishing reduction of a carbonyl to a methylene group (see **19-61**), can also give the alkene if an a hydrogen is present.⁴⁰⁰ In most of the examples given, R can also be aryl. Other reagents⁴⁰¹ have also been used,⁴⁰² including samarium in acetic acid for desulfurization of vinyl sulfones.⁴⁰³

An important special case of RSR reduction is desulfurization of thiophene derivatives. This proceeds with concomitant reduction of the double bonds. Many compounds have been made by alkylation of thiophene (see **39**), followed by reduction to the corresponding alkane.

Thiophenes can also be desulfurized to alkenes (RCH₂CH=CHCH₂R' from **39**) with a nickel boride catalyst prepared from nickel(II) chloride and NaBH₄ in methanol.⁴⁰⁴ It is possible to reduce just one SR group of a dithioacetal by treatment with borane-pyridine in trifluoroacetic acid or in CH₂Cl₂ in the presence of AlCl₃.⁴⁰⁵ Phenyl selenides RSePh can be reduced to RH with Ph₃SnH⁴⁰⁶ and with nickel boride.⁴⁰⁷

The exact mechanisms of the Raney nickel reactions are still in doubt, though they are probably of the free-radical type.⁴⁰⁸ It has been shown that reduction of thiophene proceeds through butadiene and butene, not through 1-butanethiol or other sulfur compounds, that is, the sulfur is removed before the double bonds

14-28 Conversion of Sulfides to Organolithium Compounds

Lithio-de-phenylthio-substitution

Sulfides can be cleaved, with a phenylthio group replaced by a lithium,⁴¹⁰ by treatment with lithium or lithium naphthalenide in THF.⁴¹¹ Good yields have been obtained with R = primary, secondary, or tertiary alkyl, or allylic,⁴¹² and containing groups, such as double bonds or halogens. Dilithio compounds can be made from compounds containing two separated SPh groups, but it is also possible to replace just one SPh from a compound with two such groups on a single carbon, to give an α -lithio sulfide.⁴¹³ The reaction has also been used to prepare α -lithio ethers and α -lithio organosilanes.⁴¹⁰ For some of these compounds lithium 1-(dimethylamino)naphthalenide is a better reagent than either Li or lithium naphthalenide.⁴¹⁴ The mechanism is presumably of the free-radical type.

CARBON AS LEAVING GROUP

14-29 Decarboxylative Dimerization: The Kolbe Reaction

De-carboxylic-coupling

Electrolysis of carboxylate ions, results in decarboxylation and combination of the resulting radicals to give the coupling product R–R. This coupling

reaction is called the *Kolbe reaction* or the *Kolbe electrosynthesis*.⁴¹⁵ It is used to prepare symmetrical R–R, where R is straight chained, since little or no yield is obtained when there is a branching. The reaction is not successful for R = aryl. Many functional groups may be present, though many others inhibit the reaction.⁴¹⁵ Unsymmetrical RR' have been made by coupling mixtures of acid salts.

A free-radical mechanism is involved:

There is much evidence⁴¹⁶ for this mechanism, including side products (RH, alkenes) characteristic of free-radical intermediates and the fact that electrolysis of acetate ion in the presence of styrene caused some of the styrene to polymerize to polystyrene (such polymerizations can be initiated by free radicals, see p. 1015). Other side products (ROH, RCOOR) are sometimes found, stemming from further oxidation of the radical R• to a carbocation R⁺.⁴¹⁷

When the reaction is conducted in the presence of 1,3-dienes, additive dimerization can occur:⁴¹⁸

The radical R• adds to the conjugated system to give RCH₂CH=CHCH₂•, which dimerizes. Another possible product is RCH₂CH=CHCH₂R, from coupling of the two kinds of radicals.⁴¹⁹

In a nonelectrolytic reaction, which is limited to R = primary alkyl, the thiohydroxamic esters **40** give dimers when irradiated at –64°C in an argon

atmosphere:⁴²⁰

In another nonelectrolytic process, aryl acetic acids are converted to *vic*-diaryl compounds $2\text{ArCR}_2\text{COOH} \rightarrow \text{ArCR}_2\text{CR}_2\text{Ar}$ by treatment with sodium persulfate $\text{Na}_2\text{S}_2\text{O}_8$ and a catalytic amount of AgNO_3 .⁴²¹ Photolysis of carboxylic acids in the presence of Hg_2F_2 leads to the dimeric alkane via decarboxylation.⁴²² Both of these reactions involve dimerization of free radicals. In still another process, electron-deficient aromatic acyl chlorides are dimerized to biaryls ($2\text{ArCOCl} \rightarrow \text{Ar}-\text{Ar}$) by treatment with a disilane R_3SiSiR_3 and a palladium catalyst.⁴²³

14-30 The Hunsdiecker Reaction

Bromo-de-carboxylation

Reaction of a silver salt of a carboxylic acid with bromine is called the *Hunsdiecker reaction*⁴²⁴ and is a way of decreasing the length of a carbon chain by one unit.⁴²⁵ The reaction is of wide scope, giving good results for *n*-alkyl R from 2 to 18 carbons and for many branched R too, producing primary, secondary, and tertiary bromides. Many functional groups may be present as long as they are not a substituted. The group R may also be aryl. However, if R contains unsaturation, the reaction seldom gives good results. Although bromine is the most often used halogen, chlorine and iodine have also been used. Catalytic Hunsdiecker reactions are known.⁴²⁶

When iodine is the reagent, the ratio between the reactants is very important and determines the products. A 1:1 ratio of salt/iodine gives the alkyl halide, as above.

⁴²³Krafft, T.E.; Rich, J.D.; McDermott, P.J. *J. Org. Chem.* **1990**, *55*, 5430.

⁴²⁴This reaction was first reported by the Russian composer-chemist Alexander Borodin: *Liebigs Ann. Chem.* **1861**, *119*, 121.

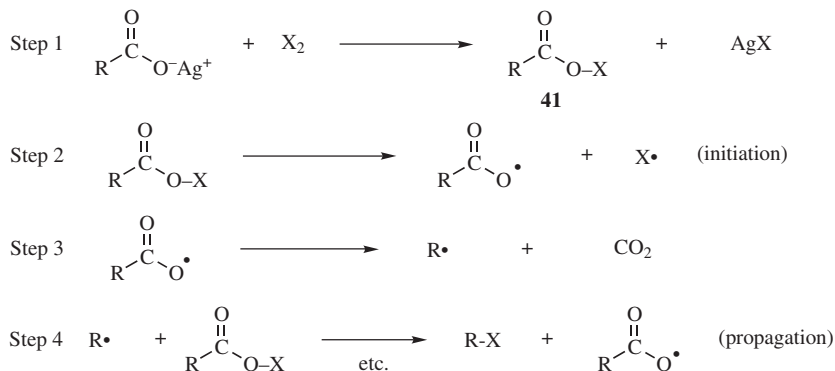

⁴²⁵For reviews, see Wilson, C.V. *Org. React.* **1957**, *9*, 332; Johnson, R.G.; Ingham, R.K. *Chem. Rev.* **1956**, *56*, 219. Also see, Naskar, D.; Chowdhury, S.; Roy, S. *Tetrahedron Lett.* **1998**, *39*, 699.

⁴²⁶Das, J.P.; Roy, S. *J. Org. Chem.* **2002**, *67*, 7861.

A 2:1 ratio, however, gives the ester RCOOR. This is called the *Simonini reaction* and is sometimes used to prepare carboxylic esters. The Simonini reaction can also be carried out with lead salts of acids.⁴²⁷ A more convenient way to perform the Hunsdiecker reaction is by use of a mixture of the acid and mercuric oxide instead of the salt, since the silver salt must be very pure and dry and such pure silver salts are often not easy to prepare.⁴²⁸

Other methods for accomplishing the conversion $\text{RCOOH} \rightarrow \text{RX}$ are⁴²⁹ (1) treatment of thallium(I) carboxylates⁴³⁰ with bromine;⁴³¹ (2) treatment of carboxylic acids with lead tetraacetate and halide ions (Cl^- , Br^- , or I^-);⁴³² (3) reaction of the acids with lead tetraacetate and NCS, which gives tertiary and secondary chlorides in good yields, but is not good for R = primary alkyl or phenyl;⁴³³ (4) treatment of thiohydroxamic esters with CCl_4 , BrCCl_3 (which gives bromination), CHI_3 , or CH_2I_2 in the presence of a radical initiator;⁴³⁴ (5) photolysis of benzophenone oxime esters of carboxylic acids in CCl_4 ($\text{RCON}=\text{CPh}_2 \rightarrow \text{RCl}$).⁴³⁵ Alkyl fluorides can be prepared in moderate to good yields by treating carboxylic acids RCOOH with XeF_2 .⁴³⁶ This method works best for R = primary and tertiary alkyl, and benzylic. Aromatic and vinylic acids do not react.

The mechanism of the Hunsdiecker reaction is believed to be as follows:

⁴³⁶Patrick, T.B.; Johri, K.K.; White, D.H.; Bertrand, W.S.; Mokhtar, R.; Kilbourn, M.R.; Welch, M.J. *Can. J. Chem.* **1986**, *64*, 138. For another method, see Grakauskas, V. *J. Org. Chem.* **1969**, *34*, 2446.

The first step is not a free-radical process, and its actual mechanism is not known.⁴³⁷ Compound **41** is an acyl hypohalite and is presumed to be an intermediate, though it has never been isolated from the reaction mixture. Among the evidence for the mechanism is that optical activity at R is lost (except when a neighboring bromine atom is present, see p. 942); if R is neopentyl, there is no rearrangement, which would certainly happen with a carbocation; and the side products, notably RR, are consistent with a free-radical mechanism. There is evidence that the Simonini reaction involves the same mechanism as the Hunsdiecker reaction, but that the alkyl halide formed then reacts with excess RCOOAg (**10-17**) to give the ester⁴³⁸ (see also **19-12**).

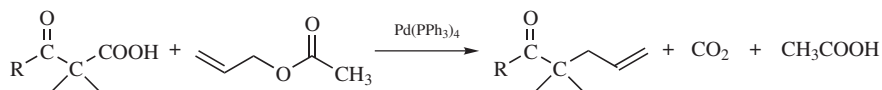

Vinyl carboxylic acids (conjugated acids) were shown to react with NBS and lithium acetate in aqueous acetonitrile, to give the corresponding vinyl bromide ($C=C-COOH \rightarrow C=C-Br$), using microwave irradiation.⁴³⁹ A similar reaction was reported using Na_2MoO_4 , KBr and aqueous hydrogen peroxide.⁴⁴⁰

A related reaction reacts the sodium salt of an alkylsulfonic acid with thionyl chloride at $100^\circ C$, to give the alkyl chloride.⁴⁴¹

14-31 Decarboxylative Allylation

Allyl-de-carboxylation

The COOH group of a β -keto acid is replaced by an allylic group when the acid is treated with an allylic acetate and a palladium catalyst at room temperature.⁴⁴² The reaction is successful for various substituted allylic groups. The less highly substituted end of the allylic group forms the new bond. Thus, both $\text{CH}_2=\text{CHCHMeOAc}$ and $\text{MeCH}=\text{CHCH}_2\text{OAc}$ gave $\text{O}=\text{C}(\text{R})-\overset{\overset{|}{\text{---}}}{\text{C}}-\text{CH}_2\text{CH}=\text{CHMe}$ as the product.

⁴³⁷When Br_2 reacts with aryl R, at low temperature in inert solvents, it is possible to isolate a complex containing both Br_2 and the silver carboxylate: see Bryce-Smith, D.; Isaacs, N.S.; Tumi, S.O. *Chem. Lett.* **1984**, 1471.

14-32 Decarbonylation of Aldehydes and Acyl Halides

Carbonyl-Extrusion

Aldehydes, both aliphatic and aromatic, can be decarbonylated⁴⁴³ by heating with a rhodium catalyst⁴⁴⁴ or other catalysts, such as palladium.⁴⁴⁵ $\text{RhCl(Ph}_3\text{P)}_3$ is often called *Wilkinson's catalyst*.⁴⁴⁶ In an older reaction, aliphatic (but not aromatic) aldehydes are decarbonylated by heating with di-*tert*-butyl peroxide or other peroxides,⁴⁴⁷ usually in a solution containing a hydrogen donor, such as a thiol. The reaction has also been initiated with light, and thermally (without an initiator) by heating at $\sim 500^\circ\text{C}$.

Wilkinson's catalyst has also been reported to decarbonylate aromatic acyl halides at 180°C ($\text{ArCOX} \rightarrow \text{ArX}$).⁴⁴⁸ This reaction has been carried out with acyl iodides,⁴⁴⁹ bromides, and chlorides. Aliphatic acyl halides that lack an α hydrogen also give this reaction,⁴⁵⁰ but if an α hydrogen is present, elimination takes place instead (17-17). Aromatic acyl cyanides give aryl cyanides ($\text{ArCOCN} \rightarrow \text{ArCN}$).⁴⁵¹ Aromatic acyl chlorides and cyanides can also be decarbonylated with palladium catalysts.⁴⁵²

It is possible to decarbonylate acyl halides in another way, to give alkanes ($\text{RCOCl} \rightarrow \text{RH}$). This is done by heating the substrate with tripropylsilane Pr_3SiH

in the presence of *tert*-butyl peroxide.⁴⁵³ Yields are good for R = primary or secondary alkyl and poor for R = tertiary alkyl or benzylic. There is no reaction when R = aryl. (See also the decarbonylation $\text{ArCOCl} \rightarrow \text{ArAr}$ mentioned in **14-29**.)

The mechanism of the peroxide- or light-induced reaction seems to be as follows (in the presence of thiols):⁴⁵⁴

The reaction of aldehydes with Wilkinson's catalyst goes through complexes of the form **42** and **43**, which have been trapped.⁴⁵⁵ The reaction has been shown to give retention of configuration at a chiral R;⁴⁵⁶ and deuterium labeling demonstrates that the reaction is intramolecular: RCO_D give RD.⁴⁵⁷ Free radicals are not involved.⁴⁵⁸ The mechanism with acyl halides appears to be more complicated.⁴⁵⁹

Addition to Carbon–Carbon Multiple Bonds

There are four fundamental ways in which addition to a double or triple bond can take place. Three of these are two-step processes, with initial attack by a nucleophile, or attack upon an electrophile or a free radical. The second step consists of combination of the resulting intermediate with, respectively, a positive species, a negative species, or a neutral entity. In the fourth type of mechanism, attack at the two carbon atoms of the double or triple bond is simultaneous (concerted). Which of the four mechanisms is operating in any given case is determined by the nature of the substrate, the reagent, and the reaction conditions. Some of the reactions in this chapter can take place by all four mechanistic types.

MECHANISMS

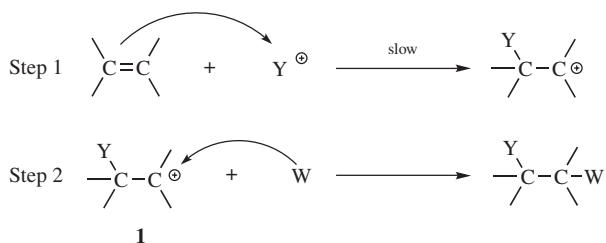

Electrophilic Addition¹

In this mechanism, a positive species approaches the double or triple bond and in the first step forms a bond by donation of the π pair of electrons² to the electrophilic

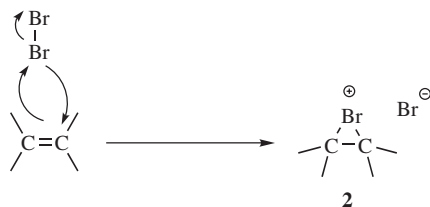

¹For a monograph, see de la Mare, P.B.D.; Bolton, R. *Electrophilic Additions to Unsaturated Systems*, 2nd ed.; Elsevier, NY, **1982**. For reviews, see Schmid, G.H., in Patai, S. *Supplement A: The Chemistry of Double-bonded Functional Groups*, Vol. 2, pt. 1, Wiley, NY, **1989**, pp. 679–731; Smit, W.A. *Sov. Sci. Rev. Sect. B* **1985**, 7, 155; V'yunov, K.A.; Ginak, A.I. *Russ. Chem. Rev.* **1981**, 50, 151; Schmid, G.H.; Garratt, D.G., in Patai, S. *Supplement A: The Chemistry of Double-bonded Functional Groups*, Vol. 1, pt. 2, Wiley, NY, **1977**, pp. 725–912; Freeman, F. *Chem. Rev.* **1975**, 75, 439; Bolton, R., in Bamford, C.H.; Tipper, C.F.H. *Comprehensive Chemical Kinetics*, Vol. 9, Elsevier, NY, **1973**, pp. 1–86; Dolbier, Jr., W.R. *J. Chem. Educ.* **1969**, 46, 342.

²For a review of the π -nucleophilicity in carbon–carbon bond-forming reactions, see Mayr, H.; Kempf, B.; Ofial, A.R. *Acc. Chem. Res.* **2003**, 36, 66.

species to form a σ pair:

The IUPAC designation for this mechanism is $A_E + A_N$ (or $A_H + A_N$ if $Y^+ = H^+$). As in electrophilic substitution (p. 658), Y need not actually be a positive ion but can be the positive end of a dipole or an induced dipole, with the negative part breaking off either during the first step or shortly after. The second step is a combination of **1** with a species carrying an electron pair and often bearing a negative charge. This step is the same as the second step of the S_N1 mechanism. Not all electrophilic additions follow the simple mechanism given above. In many brominations it is fairly certain that **1**, if formed at all, very rapidly cyclizes to a bromonium ion (**2**):

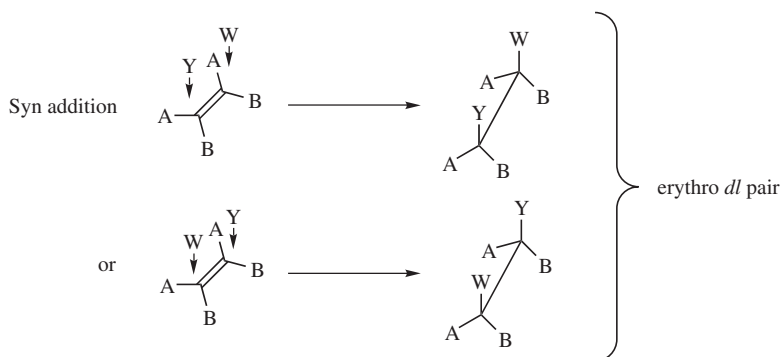

This intermediate is similar to those encountered in the neighboring-group mechanism of nucleophilic substitution (see p. 446). The attack of \bar{w} on an intermediate like **2** is an S_N2 step. Whether the intermediate is **1** or **2**, the mechanism is called Ad_E2 (electrophilic addition, bimolecular).

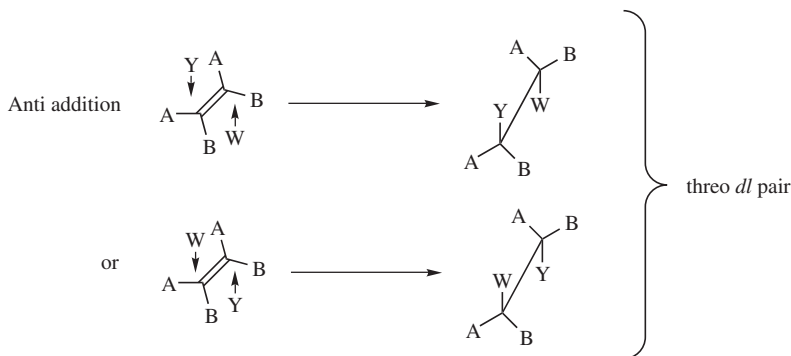

In investigating the mechanism of addition to a double bond, perhaps the most useful type of information is the stereochemistry of the reaction.³ The two carbons of the double bond and the four atoms immediately attached to them are all in a plane (p. 9); there are thus three possibilities. Both Y and W may enter from the same side of the plane, in which case the addition is stereospecific and syn; they may enter from opposite sides for stereospecific anti addition; or the reaction may be nonstereospecific. In order to determine which of these possibilities is occurring in a given reaction, the following type of experiment is often done: YW is added to the cis and trans isomers of an alkene of the form $ABC=CBA$. We may use the cis alkene as an example. If the addition is syn, the product

³For a review of the stereochemistry of electrophilic additions to double and triple bonds, see Fahey, R.C. *Top. Stereochem.* **1968**, 3, 237. For a review of the synthetic uses of stereoselective additions, see Bartlett, P.A. *Tetrahedron* **1980**, 36, 2, pp. 3–15.

will be the erythro *dl* pair, because each carbon has a 50% chance of being attacked by Y:

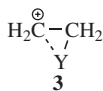

On the other hand, if the addition is anti, the threo *dl* pair will be formed:

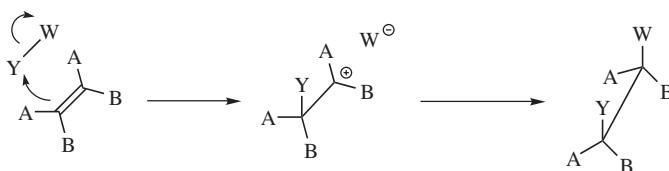

Of course, the trans isomer will give the opposite results: the threo pair if the addition is syn and the erythro pair if it is anti. The threo and erythro isomers have different physical properties. In the special case, where $Y = W$ (as in the addition of Br_2), the “erythro pair” is a meso compound. In addition to triple-bond compounds of the type $\text{AC}\equiv\text{CA}$, syn addition results in a cis alkene and anti addition in a trans alkene. By the definition given on p. 194 addition to triple bonds cannot be stereospecific, although it can be, and often is, stereoselective.

It is easily seen that in reactions involving cyclic intermediates like **2**, addition must be anti, since the second step is an $\text{S}_{\text{N}}2$ step and must occur from the back side. It is not so easy to predict the stereochemistry for reactions involving **1**. If **1** has a relatively long life, the addition should be nonstereospecific, since there will be free rotation about the single bond. On the other hand, there may be some factor that maintains the configuration, in which case W may come in from the same side or the opposite side, depending on the circumstances. For example, the positive charge might be stabilized by an attraction for Y that does not involve

a full bond (see 3).

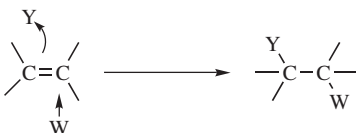

The second group would then come in anti. A circumstance that would favor syn addition would be the formation of an ion pair after the addition of Y:⁴

Since W is already on the same side of the plane as Y, collapse of the ion pair leads to syn addition.

Another possibility is that anti addition might, at least in some cases, be caused by the operation of a mechanism in which attack by W and Y are essentially simultaneous but from opposite sides:

This mechanism, called the Ad_E3 mechanism (*termolecular addition*, IUPAC $\text{A}_{\text{N}}\text{A}_{\text{E}}$),⁵ has the disadvantage that three molecules must come together in the transition state. However, it is the reverse of the $\text{E}2$ mechanism for elimination, for which the transition state is known to possess this geometry (p. 1478).

There is much evidence that when the attack is on Br^+ (or a carrier of it), the bromonium ion **2** is often an intermediate and the addition is anti. As long ago as 1911, McKenzie and Fischer independently showed that treatment of maleic acid with bromine gave the *dl* pair of 2,3-dibromosuccinic acid, while fumaric acid (the *trans* isomer) gave the meso compound.⁶ Many similar experiments have been performed since with similar results. For triple bonds, stereoselective anti addition was shown even earlier. Bromination of dicarboxyacetylene gave 70%

⁴Dewar, M.J.S. *Angew. Chem. Int. Ed.* **1964**, 3, 245; Heasley, G.E.; Bower, T.R.; Dougharty, K.W.; Eason, J.C.; Heasley, V.L.; Arnold, S.; Carter, T.L.; Yaeger, D.B.; Gipe, B.T.; Shellhamer, D.F. *J. Org. Chem.* **1980**, 45, 5150.

⁵For evidence for this mechanism, see, for example, Hammond, G.S.; Nevitt, T.D. *J. Am. Chem. Soc.* **1954**, 76, 4121; Bell, R.P.; Pring, M. *J. Chem. Soc. B* **1966**, 1119; Pincock, J.A.; Yates, K. *J. Am. Chem. Soc.* **1968**, 90, 5643; Fahey, R.C.; Payne, M.T.; Lee, D. *J. Org. Chem.* **1974**, 39, 1124; Roberts, R.M.G. *J. Chem. Soc. Perkin Trans. 2*, **1976**, 1374; Pasto, D.J.; Gadberry, J.F. *J. Am. Chem. Soc.* **1978**, 100, 1469; Naab, P.; Staab, H.A. *Chem. Ber.* **1978**, 111, 2982.

⁶This was done by Fischer, E. *Liebigs Ann. Chem.* **1911**, 386, 374; McKenzie, A. *Proc. Chem. Soc.* **1911**, 150; *J. Chem. Soc.* **1912**, 101, 1196.

of the trans isomer.⁷

There is other evidence for mechanisms involving **2**. We have already mentioned (p. 449) that bromonium ions have been isolated in stable solutions in nucleophilic substitution reactions involving bromine as a neighboring group. Such ions have also been isolated in reactions involving addition of a Br^+ species to a double bond.⁸ The following is further evidence. If the two bromines approach the double bond from opposite sides, it is very unlikely that they could come from the same bromine molecule. This means that if the reaction is performed in the presence of nucleophiles, some of these will compete in the second step with the bromide liberated from the bromine. It has been found, indeed, that treatment of ethylene with bromine in the presence of chloride ions gives some 1-chloro-2-bromoethane along with the dibromoethane.⁹ Similar results are found when the reaction is carried out in the presence of water (**15-40**) or of other nucleophiles.¹⁰ *Ab initio* molecular orbital studies show that **2** is more stable than its open isomer **1** ($\text{Y} = \text{Br}$).¹¹ There is evidence that formation of **2** is reversible.¹²

However, a number of examples have been found where addition of bromine is not stereospecifically anti. For example, the addition of Br_2 to *cis*- and *trans*-1-phenylpropenes in CCl_4 was nonstereospecific.¹³ Furthermore, the stereospecificity of bromine addition to stilbene depends on the dielectric constant of the solvent. In solvents of low dielectric constant, the addition was 90–100% anti, but with an increase in dielectric constant, the reaction became less stereospecific, until, at a dielectric constant of ~ 35 , the addition was completely nonstereospecific.¹⁴ Likewise in the case of triple bonds, stereoselective anti addition was found in bromi-

nation of 3-hexyne, but both *cis* and *trans* products were obtained in bromination of phenylacetylene.¹⁵ These results indicate that a bromonium ion is not formed where the open cation can be stabilized in other ways (e.g., addition of Br⁺ to 1-phenylpropene gives the ion PhC[⊕]HCHBrCH₃, which is a relatively stable benzylic cation) and that there is probably a spectrum of mechanisms between complete bromonium ion (**2**, no rotation) formation and completely open-cation (**1**, free rotation) formation, with partially bridged bromonium ions (**3**, restricted rotation) in between.¹⁶ We have previously seen cases (e.g., p. 461) where cations require more stabilization from outside sources as they become intrinsically less stable themselves.¹⁷ Further evidence for the open cation mechanism where aryl stabilization is present was reported in an isotope effect study of addition of Br₂ to ArCH=CHAr' (Ar = *p*-nitrophenyl, Ar' = *p*-tolyl). The ¹⁴C isotope effect for one of the double-bond carbons (the one closer to the NO₂ group) was considerably larger than for the other one.¹⁸

When the π-bond of an alkene attacks Cl⁺,¹⁹ I⁺,²⁰ and RS⁺,²¹ the result is similar to that when the electrophile is Br⁺; there is a spectrum of mechanisms between cyclic intermediates and open cations. As might be expected from our discussion in Chapter 10 (p. 446), iodonium ions compete with open carbocations more effectively than bromonium ions, while chloronium ions compete less effectively. There is kinetic and spectral evidence that at least in some cases, for example, in the addition of Br₂ or ICl, the electrophile forms a π complex with the alkene before a covalent bond is formed.²²

When the electrophile is a proton,²³ a cyclic intermediate is not possible, and the mechanism is the simple $A_H + A_N$ process shown before

This is an $A\text{-S}_{\text{E}}2$ mechanism (p. 525). There is a great deal of evidence²⁴ for it, including:

1. The reaction is general-acid, not specific-acid-catalyzed, implying rate-determining proton transfer from the acid to the double bond.²⁵
2. The existence of open carbocation intermediates is supported by the contrast in the pattern of alkyl substituent effects²⁶ with that found in brominations, where cyclic intermediates are involved. In the latter case, substitution of alkyl groups on $\text{H}_2\text{C}=\text{CH}_2$ causes a cumulative rate acceleration

until all four hydrogens have been replaced by alkyl groups, because each group helps to stabilize the positive charge.²⁷ In addition of HX , the effect is not cumulative. Replacement of the two hydrogens on one carbon causes great rate increases (primary \rightarrow secondary \rightarrow tertiary carbocation), but additional substitution on the other carbon produces little or no acceleration.²⁸ This is evidence for open cations when a proton is the electrophile.²⁹

²⁹A similar result (open cations) was obtained with carbocations Ar_2CH^+ as electrophiles: Mayr, H.; Pock, R. *Chem. Ber.* **1986**, 119, 2473.

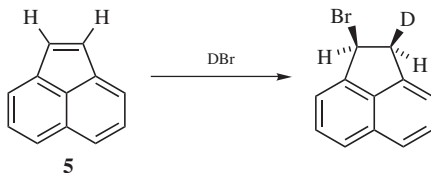

3. Open carbocations are prone to rearrange (Chapter 18). Many rearrangements have been found to accompany additions of HX and H₂O.³⁰

It may also be recalled that vinylic ethers react with proton donors in a similar manner (see 10-6).

The stereochemistry of HX addition is varied. Examples are known of predominant syn, anti, and nonstereoselective addition. It was found that treatment of 1,2-dimethylcyclohexene (**4**) with HBr gave predominant anti addition,³¹ while addition of water to **4** gave equal amounts of the cis and trans alcohols:³²

On the other hand, addition of DBr to acenaphthylene (**5**) and to indene and 1-phenylpropene gave predominant syn addition.³³

In fact, it has been shown that the stereoselectivity of HCl addition can be controlled by changing the reaction conditions. Addition of HCl to **4** in CH₂Cl₂ at –98°C gave predominantly syn addition, while in ethyl ether at 0°C, the addition was mostly anti.³⁴

Addition of HX to triple bonds has the same mechanism, although the intermediate in this case is a vinylic cation, **6**.³⁵

In all these cases (except for the $\text{A}_{\text{E}}3$ mechanism), we assumed that formation of the intermediate (**1**, **2**, or **3**) is the slow step and attack by the nucleophile on the intermediate is rapid, and this is probably true in most cases. However, some additions have been found in which the second step is rate determining.³⁶

Nucleophilic Addition³⁷

In the first step of nucleophilic addition, a nucleophile brings its pair of electrons to one carbon atom of the double or triple bond, creating a carbanion. The second step is combination of this carbanion with a positive species:

This mechanism is the same as the simple electrophilic one shown on p. 999 except that the charges are reversed (IUPAC $\text{A}_{\text{N}} + \text{A}_{\text{E}}$ or $\text{A}_{\text{N}} + \text{A}_{\text{H}}$). When the alkene contains a good leaving group (as defined for nucleophilic substitution), substitution is a side reaction (this is nucleophilic substitution at a vinylic substrate, see p. \$\$\$).

In the special case of addition of HY to a substrate of the form $\text{—C}=\text{C—Z}$, where $\text{Z} = \text{CHO}$, COR ³⁸ (including quinones³⁹), COOR , CONH_2 , CN , NO_2 , SOR ,

SO_2R ,⁴⁰ and so on, addition nearly always follows a nucleophilic mechanism,⁴¹ with Y^- bonding with the carbon *away* from the Z group, for example,

Protonation of the enolate ion is chiefly at the oxygen, which is more negative than the carbon, but this produces the enol, which tautomerizes (see p. 102). So although the net result of the reaction is addition to a carbon-carbon double bond, the *mechanism* is 1,4-nucleophilic addition to the $\text{C}=\text{C}-\text{C}=\text{O}$ (or similar) system and is thus very similar to the mechanism of addition to carbon-oxygen double and similar bonds (see Chapter 16). When Z is CN or a $\text{C}=\text{O}$ group, it is also possible for Y^- to attack at *this* carbon, and this reaction sometimes competes. When it happens, it is called 1,2-addition. 1,4-Addition to these substrates is also known as *conjugate addition*. The Y^- ion almost never attacks at the 3 position, since the resulting carbanion would have no resonance stabilization:⁴²

An important substrate of this type is acrylonitrile, and 1,4-addition to it is called *cianoethylation* because the Y is cyanoethylated:

With any substrate, when Y is an ion of the type $\text{Z}-\text{C}^\ominus \text{R}_2$ (Z is as defined above; R may be alkyl, aryl, hydrogen, or another Z), the reaction is called the *Michael reaction* (see 15-24). In this book we will call all other reactions that follow this mechanism *Michael-type additions*. Systems of the type $\text{C}=\text{C}-\text{C}=\text{C}-\text{Z}$ can give

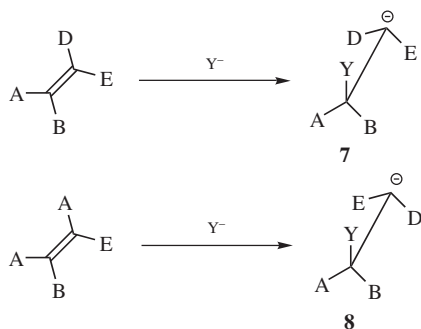

⁴⁰For a review of vinylic sulfones, see Simpkins, N.S. *Tetrahedron* **1990**, *46*, 6951. For a review of conjugate addition to cycloalkenyl sulfones, see Fuchs, P.L.; Braish, T.F. *Chem. Rev.* **1986**, *86*, 903.

⁴¹For a review of the mechanism with these substrates, see Bernasconi, C.F. *Tetrahedron* **1989**, *45*, 4017.

⁴²For 1,8-addition to a trienone, see Barbot, F.; Kadib-Elban, A.; Miginiac, P. *J. Organomet. Chem.* **1988**, *345*, 239.

1,2-1,4- or 1,6-addition.⁴³ Michael-type reactions are reversible, and compounds of the type YCH_2CH_2Z can often be decomposed to YH and $CH_2=CHZ$ by heating, either with or without alkali.

If the mechanism for nucleophilic addition is the simple carbanion mechanism outlined on p. 1007, the addition should be nonstereospecific, although it might well be stereoselective (see p. 194 for the distinction). For example, the (*E*) and (*Z*) forms of an alkene $ABC=CDE$ would give **7** and **8**.

If the carbanion has even a short lifetime, **7** and **8** will assume the most favorable conformation before the attack of W . This is of course the same for both, and when W attacks, the same product will result from each. This will be one of two possible diastereomers, so the reaction will be stereoselective; but since the *cis* and *trans* isomers do not give rise to different isomers, it will not be stereospecific. Unfortunately, this prediction has not been tested on open-chain alkenes. Except for Michael-type substrates, the stereochemistry of nucleophilic addition to double bonds has been studied only in cyclic systems, where only the *cis* isomer exists. In these cases the reaction has been shown to be stereoselective, with *syn* addition reported in some cases⁴⁴ and *anti* addition in others.⁴⁵ When the reaction is performed on a Michael-type substrate, $C=C-Z$, the hydrogen does not arrive at the carbon directly but only through a tautomeric equilibrium. The product naturally assumes the most thermodynamically stable configuration, without relation to the direction of original attack of Y . In one such case (the addition of $EtOD$ and of Me_3CSD to *trans*- $MeCH=CHCOOEt$) predominant *anti* addition was found; there is evidence that the stereoselectivity here results from the final protonation of the enolate, and not from the initial attack.⁴⁶ For obvious reasons, additions to triple bonds cannot be stereospecific. As with electrophilic additions, nucleophilic additions to triple bonds are usually stereoselective and

⁴³However, attack at the 3 position has been reported when the 4 position contains one or two carbanion-stabilizing groups such as $SiMe_3$: Klumpp, G.W.; Mierop, A.J.C.; Vrieling, J.J.; Brugman, A.; Schakel, M. *J. Am. Chem. Soc.* **1985**, *107*, 6740.

⁴⁴For example, Truce, W.E.; Levy, A.J. *J. Org. Chem.* **1963**, *28*, 679.

⁴⁵For example, Truce, W.E.; Levy, A.J. *J. Am. Chem. Soc.* **1961**, *83*, 4641; Zefirov, N.S.; Yur'ev, Yu.K.; Prikazchikova, L.P.; Bykhovskaya, M.Sh. *J. Gen. Chem. USSR* **1963**, *33*, 2100.

Step 2 is an abstraction (an atom transfer), so W is nearly always univalent, either hydrogen or halogen (p. 943). Termination of the chain can occur in any of the ways discussed in Chapter 14. If **9** adds to another alkene molecule,

a dimer is formed. This can add to still another, and chains, long or short, may be built up. This is the mechanism of free-radical polymerization. Short polymeric molecules (called *telomers*), formed in this manner, are often troublesome side products in free-radical addition reactions.

When free radicals are added to 1,5- or 1,6-dienes, the initially formed radical (**10**) can add intramolecularly to the other bond, leading to a cyclic product (**11**).⁵² When the radical is generated from an precursor that gives vinyl radical **12**, however, cyclization leads to **13**, which is in equilibrium with cyclopropylcarbinyl radical (**14**) via a 5-exo-trig reaction.⁵³ A 6-endo-trig reaction leads to **15**, but unless there are perturbing substituent effects, however, cyclopropanation should be the major process.

Radicals of the type **10**, generated in other ways, also undergo these cyclizations. Both five- and six-membered rings can be formed in these reactions (see p. 1021).

The free-radical addition mechanism just outlined predicts that the addition should be non-stereospecific, at least if **9** has any, but an extremely short lifetime. However, the reactions may be stereoselective, for reasons similar to those discussed for nucleophilic addition on p. 1007. Not all free-radical additions have been found to be selective, but many are. For example, addition of HBr to 1-bromocyclohexene is regioselective in that it gave only *cis*-1,2-dibromocyclohexane

⁵²For reviews of these and other free-radical cyclization reactions, see RajanBabu, T.V. *Acc. Chem. Res.* **1991**, *24*, 139; Beckwith, A.L.J. *Rev. Chem. ⁵³Denis, R.C.; Rancourt, J.; Ghio, E.; Boutonnet, F.; Gravel, D. *Tetrahedron Lett.* **1993**, *34*, 2091.

and none of the trans isomer (anti addition),⁵⁴ and propyne (at -78 to -60°C) gave only *cis*-1-bromopropene (anti addition), making it stereoselective.⁵⁵ However, stereospecificity has been found only in a few cases. Selectivity was observed in radical cyclization reactions of functionalized alkenes, which proceeded via a trans-ring closure.⁵⁶ The most important case is probably addition of HBr to 2-bromo-2-butene under free-radical conditions at -80°C . Under these conditions, the *cis* isomer gave 92% of the meso product, while the *trans* isomer gave mostly the *dl* pair.⁵⁷ This stereospecificity disappeared at room temperature, where both alkenes gave the same mixture of products ($\sim 78\%$ of the *dl* pair and 22% of the meso compound), so the addition was still stereoselective but no longer stereospecific. The stereospecificity at low temperatures is probably caused by a stabilization of the intermediate radical through the formation of a bridged bromine radical, of the type mentioned on p. 942:

This species is similar to the bromonium ion that is responsible for stereospecific anti addition in the electrophilic mechanism. Further evidence for the existence of such bridged radicals was obtained by addition of $\text{Br}\cdot$ to alkenes at 77 K. The ESR spectra of the resulting species were consistent with bridged structures.⁵⁸

For many radicals, step 1 ($\text{C}=\text{C} + \text{Y}\cdot \rightarrow \cdot\text{C}-\text{C}-\text{Y}$) is reversible. In such cases, free radicals can cause *cis* \rightarrow *trans* isomerization of a double bond by the pathway⁵⁹

Cyclic Mechanisms

There are some addition reactions where the initial attack is not at one carbon of the double bond, but both carbons are attacked simultaneously. Some of these are

four-center mechanisms, which follow this pattern:

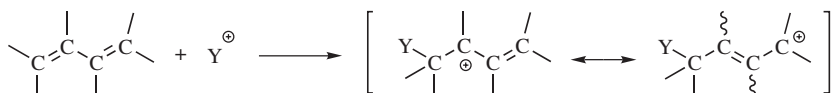

In others, there is a five- or a six-membered transition state. In these cases the addition to the double or triple bond must be syn. The most important reaction of this type is the Diels–Alder reaction (15-60).

Addition to Conjugated Systems

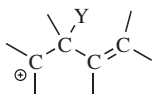

When electrophilic addition is carried out on a compound with two double bonds in conjugation, a 1,2-addition product (16) is often obtained, but in most cases there is also a 1,4-addition product (17), often in larger yield:⁶⁰

If the diene is unsymmetrical, there may be two 1,2-addition products. The competition between two types of addition product comes about because the carbocation resulting from attack on Y^+ is a resonance hybrid, with partial positive charges at the 2 and 4 positions:

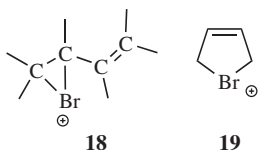

W^- may then attack either position. The original attack of Y^+ is always at the end of the conjugated system because an attack at a middle carbon would give a cation unstabilized by resonance:

In the case of electrophiles like Br^+ , which can form cyclic intermediates, both 1,2- and 1,4-addition products can be rationalized as stemming from an intermediate like 18. Direct nucleophilic attack by W^- would give the 1,2-product, while the 1,4-product could be formed by attack at the 4 position, by an S_N2' -type mechanism (see p. 470). Intermediates like 19 have been postulated, but ruled out for Br and Cl

⁶⁰For a review of electrophilic addition to conjugated dienes, see Khristov, V.Kh.; Angelov, Kh.M.; Petrov, A.A. *Russ. Chem. Rev.* **1991**, 60, 39.

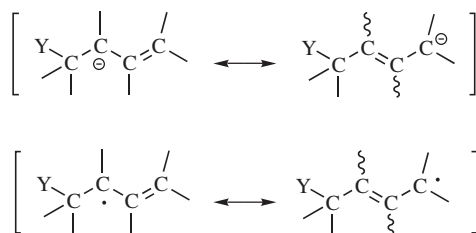

by the observation that chlorination

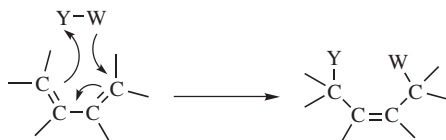

or bromination of butadiene gives trans 1,4-products.⁶¹ If an ion like **19** were the intermediate, the 1,4-products would have to have the cis configuration.

In most cases, more 1,4- than 1,2-addition product is obtained. This may be a consequence of thermodynamic control of products, as against kinetic. In most cases, under the reaction conditions, **16** is converted to a mixture of **16** and **17** which is richer in **17**. That is, either isomer gives the same mixture of both, which contains more **17**. It was found that at low temperatures, butadiene and HCl gave only 20–25% 1,4-adduct, while at high temperatures, where attainment of equilibrium is more likely, the mixture contained 75% 1,4-product.⁶² 1,2-Addition predominated over 1,4- in the reaction between DCl and 1,3-pentadiene, where the intermediate was the symmetrical (except for the D label) $\text{H}_3\text{CHC}^{\ominus}\text{---CH---CHCH}_2\text{D}$ ⁶³

Ion pairs were invoked to explain this result, since a free ion would be expected to be attacked by Cl^- equally well at both positions, except for the very small isotope effect.

Addition to conjugated systems can also be accomplished by any of the other three mechanisms. In each case, there is competition between 1,2- and 1,4-addition. In the case of nucleophilic or free-radical attack,⁶⁴ the intermediates are resonance hybrids and behave like the intermediate from electrophilic attack. Dienes can give 1,4-addition by a cyclic mechanism in this way:

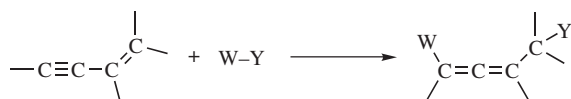

⁶¹Mislow, K. *J. Am. Chem. Soc.* **1953**, 75, 2512.

⁶⁴For a review of free-radical addition to conjugated dienes, see Afanas'ev, I.B.; Samokhvalov, G.I. *Russ. Chem. Rev.* **1969**, 38, 318.

Other conjugated systems, including trienes, enynes, diynes, and so on, have been studied much less, but behave similarly. 1,4-Addition to enynes is an important way of making allenes:

Radical addition to conjugated systems is an important part of chain propagation reactions. The rate constants for addition of cyclohexyl radical to conjugated amides have been measured, and shown to be faster than addition to styrene.⁶⁵ In additions to $\text{RCH}=\text{C}(\text{CN})_2$ systems, where the R group has a chiral center, the Felkin–Ahn rule (p. 169) is followed and the reaction proceeds with high selectivity.⁶⁶ Addition of some radicals, such as $(\text{Me}_3\text{Si})_3\text{Si}\bullet$, is reversible and this can lead to poor selectivity or isomerization.⁶⁷

ORIENTATION AND REACTIVITY

Reactivity

As with electrophilic aromatic substitution (Chapter 11), electron-donating groups increase the reactivity of a double bond toward electrophilic addition and electron-withdrawing groups decrease it. This is illustrated in Tables 15.1 and 15.2.⁶⁸ As a further illustration it may be mentioned that the reactivity toward electrophilic addition of a group of alkenes increased in the order $\text{CCl}_3\text{CH}=\text{CH}_2 < \text{Cl}_2\text{CHCH}=\text{CH}_2 < \text{ClCH}_2\text{CH}=\text{CH}_2 < \text{CH}_3\text{CH}_2=\text{CH}_2$.⁶⁹ For nucleophilic addition the situation is reversed. These reactions are best carried out on substrates containing three or four electron-withdrawing groups, two of the most common being $\text{F}_2\text{C}=\text{CF}_2$ ⁷⁰ and $(\text{NC})_2\text{C}=\text{C}(\text{CN})_2$.⁷¹ The effect of substituents is so great that it is possible to make the statement that *simple alkenes do not react by the nucleophilic mechanism, and polyhalo or polycyano alkenes do not generally react by the electrophilic mechanism.*⁷²

⁷²Such reactions can take place under severe conditions. For example, electrophilic addition could be accomplished with $\text{F}_2\text{C}=\text{CHF}$ in super acid solutions [Olah, G.A.; Mo, Y.K. *J. Org. Chem.* **1972**, 37, 1028] although $\text{F}_2\text{C}=\text{CF}_2$ did not react under these conditions. For reviews of electrophilic additions to fluoroalkenes, see Belen'kii, G.G.; German, L.S. *Sov. Sci. Rev. Sect. B* **1984**, 5, 183; Dyatkin, B.L.; Mochalina, E.P.; Knunyants, I.L. *Russ. Chem. Rev.* **1966**, 35, 417; *Fluorine Chem. Rev.* **1969**, 3, 45; Chambers, R.D.; Mobbs, R.H. *Adv. Fluorine Chem.* **1965**, 4, 51, pp. 77–81.

TABLE 15.1. Relative Reactivity of Some Alkenes Toward Bromine in Acetic Acid at 24°C⁶⁸

Alkene	Relative Rate
PhCH=CH ₂	Very fast
PhCH=CHPh	18
CH ₂ =CHCH ₂ Cl	1.6
CH ₂ =CHCH ₂ Br	1.0
PhCH=CHBr	0.11
CH ₂ =CHBr	0.0011

TABLE 15.2. Relative Reactivity of Some Alkenes Toward Bromine in Methanol⁶⁸

Alkene	Relative Rate
CH ₂ =CH ₂	3.0×10^1
CH ₃ CH ₂ CH=CH ₂	$2/9 \times 10^3$
<i>cis</i> -CH ₃ CH ₂ CH=CHCH ₃	1.3×10^5
(CH ₃) ₂ C=C(CH ₃) ₂	2.8×10^7

There are some reagents that attack only as nucleophiles, for example, ammonia, and these add only to substrates susceptible to nucleophilic attack. Other reagents attack only as electrophiles, and, for example, F₂C=CF₂ does not react with these. In still other cases, the same reagent reacts with a simple alkene by the electrophilic mechanism and with a polyhalo alkene by a nucleophilic mechanism. For example, Cl₂ and HF are normally electrophilic reagents, but it has been shown that Cl₂ adds to (N≡C)₂C=CHC≡N with initial attack by Cl⁻⁷³ and that HF adds to F₂C=CClF with initial attack by F⁻⁷⁴. Compounds that have a double bond conjugated with a Z group (as defined on p. 1007) nearly always react by a nucleophilic mechanism.⁷⁵ These are actually 1,4-additions, as discussed on p. 1008. A number of studies have been made of the relative activating abilities of various Z groups.⁷⁶ On the basis of these studies, the following order of decreasing activating ability has been suggested: Z = NO₂, COAr, CHO, COR, SO₂Ar, CN, COOR, SOAr, CONH₂, CONHR.⁷⁷

It seems obvious that electron-withdrawing groups enhance nucleophilic addition and inhibit electrophilic addition because they lower the electron density of

⁷³Dickinson, C.L.; Wiley, D.W.; McKusick, B.C. *J. Am. Chem. Soc.* **1960**, *82*, 6132. For another example, see Atkinson, R.C.; de la Mare, P.B.D.; Larsen, D.S. *J. Chem. Soc. Perkin Trans. 2*, **1983**, 271.

⁷⁵For a review of electrophilic reactions of such compounds, see Müllen, K.; Wolf, P., in Patai, S.; Rappoport, Z. *The Chemistry of Enones*, pt. 1, Wiley, NY, **1989**, pp. 513–558.

⁷⁶See, for example, Friedman, M.; Wall, J.S. *J. Org. Chem.* **1966**, *31*, 2888; Ring, R.N.; Tesoro, G.C.; Moore, D.R. *J. Org. Chem.* **1967**, *32*, 1091.

⁷⁷Shenhav, H.; Rappoport, Z.; Patai, S. *J. Chem. Soc. B* **1970**, 469.

the double bond. Addition of electrophilic radicals to electron rich alkenes has been reported,⁷⁸ so the reaction is possible in some cases. This is probably true, and yet similar reasoning does not always apply to a comparison between double and triple bonds.⁷⁹ There is a higher concentration of electrons between the carbons of a triple bond than in a double bond, and yet triple bonds are *less* subject to attack at an electrophilic site and *more* subject to nucleophilic attack than double bonds.⁸⁰ This statement is not universally true, but it does hold in most cases. In compounds containing both double and triple bonds (nonconjugated), bromine, an electrophilic reagent, always adds to the double bond.⁸¹ In fact, all reagents that form bridged intermediates like **2** react faster with double than with triple bonds. On the other hand, addition of electrophilic H⁺ (acid-catalyzed hydration, **15-3**; addition of hydrogen halides, **15-2**) takes place at about the same rates for alkenes as for corresponding alkynes.⁸² Furthermore, the presence of electron-withdrawing groups lowers the alkene/alkyne rate ratio. For example, while styrene PhCH=CH₂ was brominated 3000 times faster than PhC≡CH, the addition of a second phenyl group (PhCH=CHPh versus PhC≡CPh) lowered the rate ratio to about 250.⁸³ In the case of *trans*-MeOOCCH=CHCOOMe versus MeOOC≡CCOOMe, the triple bond compound was actually brominated faster.⁸⁴

As mentioned, it is true that in general triple bonds are more susceptible to nucleophilic and less to attack on an electrophilic site than double bonds, in spite of their higher electron density. One explanation is that the electrons in the triple bond are held more tightly because of the smaller carbon-carbon distance; it is thus harder for an attacking electrophile to pull out a pair. There is evidence from far-UV spectra to support this conclusion.⁸⁵ Another possible explanation has to do with the availability of the unfilled orbital in the alkyne. It has been shown that a π* orbital of bent alkynes (e.g., cyclooctyne) has a lower energy than the π* orbital of alkenes, and it has been suggested⁸⁶ that linear alkynes can achieve a bent structure in their transition states when reacting with an electrophile. Where electrophilic addition involves bridged-ion intermediates, those arising from triple bonds (**20**) are more strained than the corresponding **21** and furthermore are antiaromatic systems

(see p. 73), which **21** are not. This may be a reason why electrophilic addition by such electrophiles as Br, I, SR, and so on, is slower for triple than for double bonds.⁸⁷ As might be expected, triple bonds connected to a Z group (C≡C-Z) undergo nucleophilic addition especially well.⁸⁸

Although alkyl groups in general increase the rates of electrophilic addition, we have already mentioned (p. 1005) that there is a different pattern depending on whether the intermediate is a bridged ion or an open carbocation. For brominations and other electrophilic additions in which the first step of the mechanism is rate determining, the rates for substituted alkenes correlate well with the ionization potentials of the alkenes, which means that steric effects are not important.⁸⁹ Where the second step is rate determining [e.g., oxymercuration (**15-3**), hydroboration (**15-17**)], steric effects are important.⁸⁸

Free-radical additions can occur with any type of substrate. The determining factor is the presence of a free-radical attacking species. Some reagents (e.g., HBr, RSH) attack by ionic mechanisms if no initiator is present, but in the presence of a free-radical initiator, the mechanism changes and the addition is of the free-radical type. Nucleophilic radicals (see p. 938) behave like nucleophiles in that the rate is increased by the presence of electron-withdrawing groups in the substrate. The reverse is true for electrophilic radicals.⁹⁰ However, nucleophilic radicals react with alkynes more slowly than with the corresponding alkenes,⁹¹ which is contrary to what might have been expected.⁹²

22

⁸⁷Nevertheless, bridged ions **15** have been implicated in some additions to triple bonds. See, for example, Pincock, J.A.; Yates, K. *Can. J. Chem.* **1970**, *48*, 3332; Mauger, E.; Berliner, E. *J. Am. Chem. Soc.* **1972**, *94*, 194; Bassi, P.; Tonellato, U. *J. Chem. Soc. Perkin Trans. 1*, **1973**, 669; Schmid, G.H.; Modro, A.; Lenz, F.; Garratt, D.G.; Yates, K. *J. Org. Chem.* **1976**, *41*, 2331.

⁸⁸For a review of additions to these substrates, see Winterfeldt, E. *Angew. Chem. Int. Ed.* **1967**, *6*, 423; *Newer Methods Prep. Org. Chem.* **1971**, *6*, 243.

⁸⁹Nelson, D.J.; Cooper, P.J.; Soundararajan, R. *J. Am. Chem. Soc.* **1989**, *111*, 1414; Nelson, D.J.; Soundararajan, R. *Tetrahedron Lett.* **1988**, *29*, 6207.

⁹¹Giese, B.; Lachhein, S. *Angew. Chem. Int. Ed.* **1982**, *21*, 768.

⁹²For a discussion of reactivity and orientation of polar radicals, see Volovik, S.V.; Dyadyusha, G.G.; Staninets, V.I. *J. Org. Chem. USSR* **1986**, *22*, 1224.

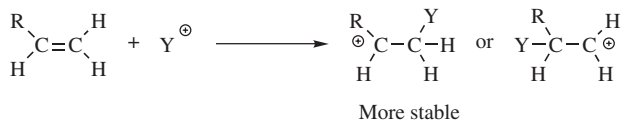

Steric influences are important in some cases. In catalytic hydrogenation, where the substrate must be adsorbed onto the catalyst surface, the reaction becomes more difficult with increasing substitution. The hydrocarbon **22**, in which the double bond is entombed between the benzene rings, does not react with Br_2 , H_2SO_4 , O_3 , BH_3 , $:\text{CBr}_2$, or other reagents that react with most double bonds.⁹³ A similarly inactive compound is tetra-*tert*-butylallene $(t\text{-Bu})_2\text{C}=\text{C}=\text{C}(t\text{-Bu})_2$, which is inert to Br_2 , Cl_2 , O_3 , and catalytic hydrogenation.⁹⁴

Orientation

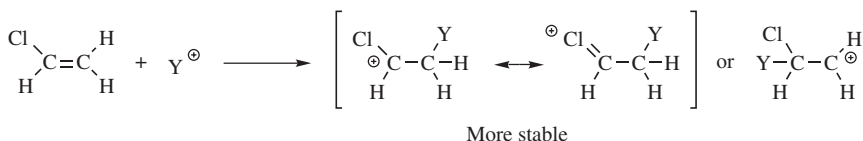

When an unsymmetrical reagent is added to an unsymmetrical substrate, the question arises: Which side of the reagent goes to which side of the double or triple bond? The terms side and face are arbitrary, and a simple guide is shown to help understand the arguments used here. For electrophilic attack, the answer is given by

*Markovnikov's rule: The positive portion of the reagent goes to the side of the double or triple bond that has more hydrogens.*⁹⁵ A number of explanations have been suggested for this regioselectivity, but the most probable is that Y^+ adds to that side that will give the more stable carbocation. This premise has been examined by core electron spectroscopy and by theoretical analysis.⁹⁶ Thus, when an alkyl group is present, secondary carbocations are more stable than primary:

We may ask: Why does Y^+ add to give the more stable carbocation? As in the similar case of electrophilic aromatic substitution (p. 658), we invoke the Hammond postulate and say that the lower energy carbocation is preceded by the lower energy transition state. Markovnikov's rule also applies for halogen substituents because the halogen stabilizes the carbocation by resonance:

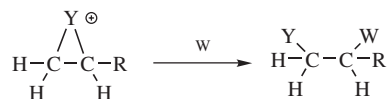

⁹³Butler, D.N.; Gupta, I.; Ng, W.W.; Nyburg, S.C. *J. Chem. Soc., Chem. Commun.* **1980**, 596.

⁹⁴Bolze, R.; Eierdanz, H.; Schlüter, K.; Massa, W.; Grahn, W.; Berndt, A. *Angew. Chem. Int. Ed.* **1982**, *21*, 924.

⁹⁵For discussions of Markovnikov's rule, see Isenberg, N.; Grdinic, M. *J. Chem. Educ.* **1969**, *46*, 601; Grdinic, M.; Isenberg, N. *Intra-Sci. Chem. Rep.*, **1970**, *4*, 145–162.

⁹⁶Sæthre, L.J.; Thomas, T.D.; Svensson, S. *J. Chem. Soc. Perkin Trans. 2*, **1997**, 749.

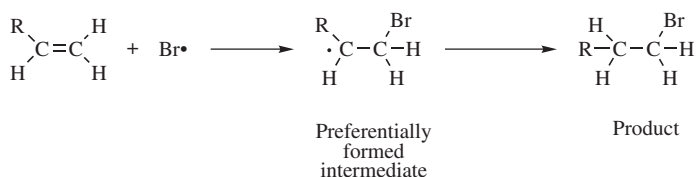

Markovnikov's rule is also usually followed where bromonium ions or other three-membered rings are intermediates.⁹⁷ This means that in these cases attack by *W* must resemble the S_N1 rather than the S_N2 mechanism (see p. 517), although the overall stereospecific anti addition in these reactions means that the nucleophilic substitution step is taking place with inversion of configuration.

Alkenes containing strong electron-withdrawing groups may violate Markovnikov's rule. For example, attack at the Markovnikov position of $\text{Me}_3\text{N}^+-\text{CH}=\text{CH}_2$ would give an ion with positive charges on adjacent atoms. The compound $\text{CF}_3\text{CH}=\text{CH}_2$ has been reported to give electrophilic addition with acids in an anti-Markovnikov direction, but it has been shown⁹⁸ that, when treated with acids, this compound does not give simple electrophilic addition at all; the apparently anti-Markovnikov products are formed by other pathways. Molecular electrostatic potentials for the π -region of substituted alkenes were studied, with electron donating and withdrawing substituents (based on the increase or decrease in the negative character of V_{min} -most negative-valued point), and plots of V_{min} shows a good linear correlation with the Hammett $\sigma\rho$ constants, suggesting similar substituent electronic effects for substituted ethylenes and substituted benzenes.⁹⁹

For nucleophilic addition the direction of attack has been studied very little, except for Michael-type addition, with compounds of the type $\text{C}=\text{C}-\text{Z}$. Here the negative part of the reagent almost always attacks regioselectively at the carbon that does not carry the *Z* (see p. 1008).

In free-radical addition¹⁰⁰ the main effect seems to be steric.¹⁰¹ All substrates $\text{CH}_2=\text{CHX}$ preferentially react at the CH_2 , regardless of the identity of *X* or of the radical. With a reagent such as HBr , this means that the addition is anti-Markovnikov:

⁹⁷This has been graphically demonstrated by direct treatment of stabilized bromonium ions by nucleophiles: Dubois, J.E.; Chrétien, J.R. *J. Am. Chem. Soc.* **1978**, *100*, 3506.

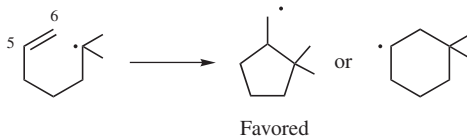

⁹⁸Myhre, P.C.; Andrews, G.D. *J. Am. Chem. Soc.* **1970**, *92*, 7595, 7596. See also, Newton, T.A. *J. Chem. Educ.* **1987**, *64*, 531.

⁹⁹Suresh, C.H.; Koga, N.; Gadre, S.R. *J. Org. Chem.* **2001**, *66*, 6883.

¹⁰⁰For reviews of orientation in free-radical additions, see Tedder, J.M.; Walton, J.C. *Tetrahedron* **1980**, *36*, 701; *Adv. Phys. Org. Chem.* **1978**, *16*, 51; *Acc. Chem. Res.* **1976**, *9*, 183. See also, Giese, B. *Rev. Chem. Intermed.* **1986**, *7*, 3; Tedder, J.M. *J. Chem. Educ.* **1984**, *61*, 237.

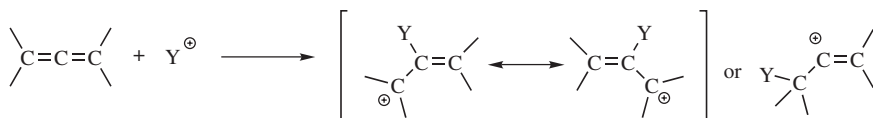

¹⁰¹See, however, Riemenschneider, K.; Bartels, H.M.; Dornow, R.; Drechsel-Grau, E.; Eichel, W.; Luthe, H.; Matter, Y.M.; Michaelis, W.; Boldt, P. *J. Org. Chem.* **1987**, *52*, 205; Gleicher, G.J.; Mahiou, B.; Aretakis, A.J. *J. Org. Chem.* **1989**, *54*, 308.

Thus the observed orientation in both kinds of HBr addition (Markovnikov electrophilic and anti-Markovnikov free radical) is caused by formation of the secondary intermediate. In the electrophilic case it forms because it is more stable than the primary; in the free-radical case because it is sterically preferred. The stability order of the free-radical intermediates is also usually in the same direction: $3^\circ > 2^\circ > 1^\circ$ (p. 272), but this factor is apparently less important than the steric factor. Internal alkenes with no groups present to stabilize the radical usually give an $\sim 1:1$ mixture via 5-exo-trig and 6-endo-trig (see Baldwin's rules p. \$\$\$) reactions.

In *intramolecular* additions of radicals containing a 5,6 double bond,⁵² both five- and six-membered rings can be formed, but in most cases¹⁰² the five-membered rings are greatly preferred kinetically, even (as in the case shown) where five-membered ring closure means generating a primary radical and six-membered ring closure a secondary radical. This phenomenon may be caused by more favorable entropy factors leading to a five-membered ring, as well as by stereoelectronic factors, but other explanations have also been offered.¹⁰³ Similar behavior is found when the double bond is in other positions (from the 3,4 to the 7,8 position). In each case, the smaller ring (exo-trig addition) is preferred to the larger (endo-trig addition)¹⁰⁴ (see the Baldwin rules, p. 305). However, when a radical that is unsaturated in the 5,6 position contains an alkyl group in the 5 position, formation of the six-membered ring is generally favored.¹⁰⁵

For conjugated dienes, attack by a positive ion, a negative ion, or a free radical is almost always at the *end* of the conjugated system, since in each case this gives an intermediate stabilized by resonance. In the case of an unsymmetrical diene, the more stable ion is formed. For example, isoprene ($\text{CH}_2=\text{CMeCH}=\text{CH}_2$), treated with HCl gives only $\text{Me}_2\text{CClCH}=\text{CH}_2$ and $\text{Me}_2\text{C}=\text{CHCH}_2\text{Cl}$, with none of the product arising from attack at the other end. $\text{PhCH}=\text{CHCH}=\text{CH}_2$ gives only $\text{PhCH}=\text{CHCHClCH}_3$ since it is the only one of the eight possible products that has a double bond in conjugation with the ring and that results from attack by H^+ at an end of the conjugated system.

¹⁰²For an exception, see Wilt, J.W. *Tetrahedron* **1985**, *41*, 3979.

When allenes attack electrophilic reagents,¹⁰⁶ Markovnikov's rule would predict that the formation of the new bond should be at the end of the system, since there are no hydrogens in the middle. Reaction at the center gives a carbocation stabilized by resonance, but not immediately. In order for such stabilization to be in effect the three *p* orbitals must be parallel, and it requires a rotation about the C—C bond for this to happen.¹⁰⁷ Therefore, the stability of the allylic cation has no effect on the transition state, which still has a geometry similar to that of the original allene (p. 148). Probably because of this, attack on the unsubstituted $\text{CH}_2=\text{C}=\text{CH}_2$ is most often at the end carbon, to give a vinylic cation, although center attack has also been reported. However, as alkyl or aryl groups are substituted on the allene carbons, attack at the middle carbon becomes more favorable because the resulting cation is stabilized by the alkyl or aryl groups (it is now a secondary, tertiary, or benzylic cation). For example, allenes of the form $\text{RCH}=\text{C}=\text{CH}_2$ are still attacked most often at the end, but with $\text{RCH}=\text{C}=\text{CHR}'$ center attack is more prevalent. Tetramethylallene is also attacked predominantly at the center carbon.¹⁰⁸ Free radicals¹⁰⁹ attack allenes most often at the end,¹¹⁰ although attack at the middle has also been reported.¹¹¹ As with electrophilic attack and for the same reason, the stability of the allylic radical has no effect on the transition state of the reaction between a free radical and an allene. Again, as with electrophilic attack, the presence of alkyl groups increases the extent of attack by a radical at the middle carbon.¹¹²

Stereochemical Orientation

It has already been pointed out that some additions are syn, with both groups, approaching from the same side, and that others are anti, with the groups approaching from opposite sides of the double or triple bond. For cyclic compounds steric orientation must be considered. In syn addition to an unsymmetrical cyclic alkene,

the two groups can come in from the more- or from the less-hindered face of the double bond. The rule is that syn addition is usually, although not always, from the less-hindered face. For example, epoxidation of 4-methylcyclopentene gave 76% addition from the less-hindered and 24% from the more-hindered face.¹¹³

In anti addition to a cyclic substrate, the initial attack on the electrophile is also from the less-hindered face. However, many (although not all) electrophilic additions to norbornene and similar strained bicycloalkenes are syn additions.¹¹⁴ In these cases reaction is always from the exo side, as in formation of **23**,¹¹⁵

unless the exo side is blocked by substituents in the 7 position, in which case endo attack may predominate; for example, 7,7-dimethylnorbornene undergoes syn-endo epoxidation (**15-50**) and hydroboration¹¹⁶ (**15-16**). However, addition of DCl and F₃CCOOD to, and oxymercuration (**15-2**) of, 7,7-dimethylnorbornene proceeds syn-exo in spite of the methyl groups in the 7 position.¹¹⁷ Similarly, free-radical additions to norbornene and similar molecules are often syn-exo, although anti additions and endo attacks are also known.¹¹⁸

Electronic effects can also play a part in determining which face reacts preferentially with the electrophilic species. In the adamantane derivative **24**, steric

effects are about the same for each face of the double bond. Yet epoxidation, dibromocarbene reactions (**15-64**), and hydroboration (**15-16**) all predominantly take place from the face that is syn to the electron-withdrawing fluorine.¹¹⁹ In the case shown, about twice as much **25** was formed, compared to **26**. Similar results have been obtained on other substrates:¹²⁰ groups that are electron withdrawing by the field effect ($-I$) direct attack from the syn face; $+I$ groups from the anti face, for both electrophilic and nucleophilic attack. These results are attributed¹²¹ to hyperconjugation: For the adamantane case, there is overlap between the σ^* orbital of the newly forming bond (between the attacking species and C-2 in **24**) and the filled σ orbitals of the $C_\alpha-C_\beta$ bonds on the opposite side. This is called the *Cieplak effect*. The LiAlH_4 reduction of 2-axial methyl or methoxy cyclohexanones supports Cieplak's proposal.¹²² In addition reactions of methanol to norbornanones, however, little evidence was found to support the Cieplak effect.¹²³ The four possible bonds are C-3-C-4 and C-1-C-9 on the syn side and C-3-C-10 and C-1-C-8 on the anti side. The preferred pathway is the one where the incoming group has the more electron-rich bonds on the side *opposite* to it (these are the ones it overlaps with). Since the electron-withdrawing F has its greatest effect on the bonds closest to it, the C-1-C-8 and C-3-C-10 bonds are more electron rich, and the group comes in on the face syn to the F.

It has been mentioned that additions of Br_2 and HOBr are often anti because of formation of bromonium ions and that free-radical addition of HBr is also anti. When the substrate in any of these additions is a cyclohexene, the addition is not only anti but the initially formed product is conformationally specific too, being mostly diaxial.¹²⁴ This is so because diaxial opening of the three-membered ring preserves a maximum coplanarity of the participating centers in the transition state; indeed, on opening, epoxides also give diaxial products.¹²⁵ However, the initial diaxial product may then pass over to the diequatorial conformer unless other groups on the ring render the latter less stable than the former. In free-radical additions to cyclohexenes in which cyclic intermediates are not involved, the initial reaction with the radical is also usually from the axial direction,¹²⁶ resulting in a diaxial initial product if the overall addition is anti. The direction from which unsymmetrical radicals react has also been studied.¹²⁷ For example, when the radical **27** adds

to a double bond it preferentially does so anti to the OH group, leading to a diaxial trans product.¹²⁵

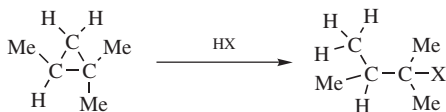

Addition to Cyclopropane Rings¹²⁸

We have previously seen (p. 218) that in some respects, cyclopropane rings resemble double bonds.¹²⁹ It is not surprising, therefore, that cyclopropanes undergo addition reactions analogous to those undergone by double-bond compounds, resulting in the opening of the three-membered rings, as in the two examples shown where reaction numbers relating the reaction to alkene chemistry are in parentheses.

Other examples are discussed at **15-3**, **15-15**, and **15-63**.

Additions to cyclopropanes can take place by any of the four mechanisms already discussed in this chapter, but the most important type involves attack on an electrophile.¹³¹ For substituted cyclopropanes, these reactions usually follow Markovnikov's rule, although exceptions are known and the degree of regioselectivity is often small. The application of Markovnikov's rule to these substrates can be illustrated by the reaction of 1,1,2-trimethylcyclopropane with HX.¹³² The rule predicts that the electrophile (in this case H⁺) goes to the carbon

¹²⁸For a review, see Charton, M., in Zabicky, J. *The Chemistry of Alkenes*, Vol 2., Wiley, NY, **1970**, pp. 569–592. with the most hydrogens and the nucleophile goes to the carbon that can best stabilize a positive charge (in this case the tertiary rather than the secondary carbon). The stereochemistry of the reaction can be investigated at two positions the one that becomes connected to the electrophile and the one that becomes connected to the nucleophile. The results at the former position are mixed. Additions have been found to take place with 100% retention,¹³³ 100% inversion,¹³⁴ and with mixtures of retention and inversion.¹³⁵ At the carbon that becomes connected to the nucleophile the result is usually inversion, although retention has also been found,¹³⁶ and elimination, rearrangement, and racemization processes often compete, indicating that in many cases a positively charged carbon is generated at this position.

At least three mechanisms have been proposed for electrophilic addition (these mechanisms are shown for attack by HX, but analogous mechanisms can be written for other electrophiles).

Mechanism *a* involves a corner-protonated cyclopropane¹³⁷ (**28**); we have already seen examples of such ions in the 2-norbornyl and 7-norbornenyl cations (pp. 453, 460). Mechanism *b* involves an edge-protonated cyclopropane (**29**). Mechanism *c*

¹³³For example, see DePuy, C.H.; Breitbeil, F.W.; DeBruin, K.R. *J. Am. Chem. Soc.* **1966**, *88*, 3347; Hendrickson, J.B.; Boeckman, Jr., R.K. *J. Am. Chem. Soc.* **1969**, *91*, 3269.

¹³⁴For example, see LaLonde, R.T.; Ding, J.; Tobias, M.A. *J. Am. Chem. Soc.* **1967**, *89*, 6651; Warnet, R.J.; Wheeler, D.M.S. *Chem. ¹³⁶Cristol, S.J.; Lim, W.Y.; Dahl, A.R. *J. Am. Chem. Soc.* **1970**, *92*, 4013; Hendrickson, J.B.; Boeckman, Jr., R.K. *J. Am. Chem. Soc.* **1971**, *93*, 4491.

¹³⁷For reviews of protonated cyclopropanes, see Collins, C.J. *Chem. Rev.* **1969**, *69*, 543; Lee, C.C. *Prog. Phys. Org. Chem.* **1970**, *7*, 129.

consists of a one-step S_E2 -type attack on H^+ to give the classical cation **30**, which then reacts with the nucleophile. Although the three mechanisms as we have drawn them show retention of configuration at the carbon that becomes attached to the proton, mechanisms *a* and *c* at least can also result in inversion at this carbon. Unfortunately, the evidence on hand at present does not allow us unequivocally to select any of these as the exclusive mechanism in all cases. Matters are complicated by the possibility that more than one edge-protonated cyclopropane is involved, at least in some cases. There is strong evidence for mechanism *b* with the electrophiles Br^+ and Cl^+ ,¹³⁸ and for mechanism *a* with D^+ and Hg^{2+} .¹³⁹ *Ab initio* studies show that the corner-protonated **28** is slightly more stable ($\sim 1.4 \text{ kcal mol}^{-1}$, 6 kJ mol^{-1}) than the edge-protonated **29**.¹⁴⁰ There is some evidence against mechanism *c*.¹⁴¹

Free-radical additions to cyclopropanes have been studied much less, but it is known that Br_2 and Cl_2 add to cyclopropanes by a free-radical mechanism in the presence of UV light. The addition follows Markovnikov's rule, with the initial radical reacting at the least-substituted carbon and the second group going to the most-substituted position. Several investigations have shown that the reaction is stereospecific at one carbon, taking place with inversion there, but nonstereospecific at the other carbon.¹⁴² A mechanism that accounts for this behavior is¹⁴³

In some cases, conjugate addition has been performed on systems where a double bond is "conjugated" with a cyclopropyl ring. An example is the formation of **31**.¹⁴⁴

REACTIONS

Reactions are classified by type of reagent. Isomerization of double and triple bonds is followed by examination of all reactions, where hydrogen adds to one side of the double or triple bond.

ISOMERIZATION OF DOUBLE AND TRIPLE BONDS

15-1 Isomerization

There are several reagents that lead to isomerization of a double bond to form a new alkene. In general, there is an energetic preference of an α,β - versus β,γ -double bond.¹⁴⁵ Transition metals have been used to induce isomerization of alkenes. Allylic arenes ($\text{Ar-CH}_2\text{CH}=\text{CH}_2$) have been converted to the corresponding (*Z*)-1-propenyl arene ($\text{Ar-CH}=\text{CHMe}$) using a ruthenium catalyst¹⁴⁶ or a polymer-supported iridium catalyst.¹⁴⁷ Allyl decyl ether ($\text{CH}_2=\text{CHCH}_2\text{OC}_{10}\text{H}_{21}$) was isomerized to 1-decyloxy-1-propene ($\text{CH}_3\text{CH}=\text{CHOC}_{10}\text{H}_{21}$) by treatment with $\text{NaHFe}(\text{CO})_4$.¹⁴⁸ Double-bond migration has been observed in sulfide photoirradiation, induced by singlet oxygen.¹⁴⁹ *N*-Acyl allylamine can be isomerized to the *N*-acyl enamine by heating with a ruthenium catalyst.¹⁵⁰ Many of these reactions were discussed in **12-2**.

For conjugated carbonyl compounds that have a hydrogen atom at the γ -position (C-4), it is possible to move a double bond *out* of conjugation. Photolysis of conjugated esters, at -40°C in the presence of *N,N*-dimethylaminoethanol, gave the nonconjugated ester.¹⁵¹ Heating an *N*-allylic amide ($\text{N-C-C}=\text{C}$) with $\text{Fe}(\text{CO})_5$, neat, gave the enamide ($\text{N-C}=\text{C-C}$).¹⁵²

Isomerization of (*E/Z*) isomers is another important transformation.¹⁵³ Isomerization of (*E*)- and (*Z*)-conjugated amides is effected photochemically¹⁵⁴

(photoisomerization¹⁵⁵). There is a rather high energy barrier for the excited state required for (*E/Z*) isomerization.¹⁵⁶ Isomerization of the C=C units in dienes is also induced photochemically.¹⁵⁷ Isomerization of cyclic alkenes is more difficult but cyclooctene is isomerized photochemically.¹⁵⁸ The photosensitized *cis*–*trans* isomerization of 1,2-dichloroethylenes have been reported,¹⁵⁹ and also the photoisomerization of *cis/trans* cyclooctene.¹⁶⁰ Radical-induced (*E/Z*) isomerization is known.¹⁶¹

Conjugated aldehydes have been isomerized using thiourea in DMF.¹⁶² A 1:1 mixture of *cis/trans* styrene derivatives was isomerized to a 90% yield of the *trans* styrene derivatives was reported using a palladium catalyst.¹⁶³ Thermal *cis*–*trans* isomerization of 1,3-diphenyltriazenes has been reported, in aqueous solution.¹⁶⁴

REACTIONS IN WHICH HYDROGEN ADDS TO ONE SIDE

A. Halogen on the Other Side

15-2 Addition of Hydrogen Halides

Hydro-halo-addition

Any of the four hydrogen halides can be added to double bonds.¹⁶⁵ HI, HBr, and HF¹⁶⁶ add at room temperature. The addition of HCl is more difficult and usually requires heat,²³ although HCl adds easily in the presence of silica gel.¹⁶⁷ The reaction has been carried out with a large variety of double-bond compounds, including

conjugated systems, where both 1,2- and 1,4-addition are possible. A convenient method for the addition of HF involves the use of a polyhydrogen fluoride-pyridine solution.¹⁶⁸ When the substrate is mixed with this solution in a solvent, such as THF at 0°C, alkyl fluorides are obtained in moderate-to-high yields.

The addition of hydrogen halides to simple alkenes, in the absence of peroxides, takes place by an electrophilic mechanism, and the orientation is in accord with Markovnikov's rule.¹⁶⁹ The addition follows second order kinetics.¹⁷⁰ When peroxides are added, the addition of HBr occurs by a free-radical mechanism and the orientation is anti-Markovnikov (p. 1021).¹⁷¹ It must be emphasized that this is true *only* for HBr. Free-radical addition of HF and HI has never been observed, even in the presence of peroxides, and of HCl only rarely. In the rare cases where free-radical addition of HCl was noted, the orientation was still Markovnikov, presumably because the more stable *product* was formed.¹⁷² Free-radical addition of HF, HI, and HCl is energetically unfavorable (see the discussions on pp. 943, 959). It has often been found that anti-Markovnikov addition of HBr takes place even when peroxides have not been added. This happens because the substrate alkenes absorb oxygen from the air, forming small amounts of peroxides (**14-7**). Markovnikov addition can be ensured by rigorous purification of the substrate, but in practice this is not easy to achieve, and it is more common to add inhibitors, for example, phenols or quinones, which suppress the free-radical pathway. The presence of free-radical precursors, such as peroxides does not inhibit the ionic mechanism, but the radical reaction, being a chain process, is much more rapid than the electrophilic reaction. In most cases, it is possible to control the mechanism (and hence the orientation) by adding peroxides to achieve complete free-radical addition, or inhibitors to achieve complete electrophilic addition, although there are some cases where the ionic mechanism is fast enough to compete with the free-radical mechanism and complete control cannot be attained. Markovnikov addition of HBr, HCl, and HI has also been accomplished, in high yields, by the use of phase-transfer catalysis.¹⁷³ For alternative methods of adding HBr (or HI) with anti-Markovnikov orientation, see **12-31**.

It is also possible to add 1¹⁷⁴ or 2 equivalents of any of the four hydrogen halides to triple bonds. Markovnikov's rule ensures that *gem*-dihalides and not *vic*-dihalides

are the products of the addition of two equivalents.

Chlorotrimethylsilane can be added to alkenes to give alkyl chlorides. 1-Hexene reacts with Me_3SiCl in water to give 2-chlorohexane.¹⁷⁵ Treatment of an alkene with KHF_2 and SiF_4 leads to the alkyl fluoride,¹⁷⁶ and bromotrimethylsilane adds to alkynes to give the vinyl bromide.¹⁷⁷ Trichloroisocyanuric acid reacts with terminal alkenes in water to give the 1-chloro alkane.¹⁷⁸

HX are electrophilic reagents, and many polyhalo and polycyano alkenes, for example, $Cl_2C=CHCl$, do not react with them at all in the absence of free-radical conditions. Vinylcyclopropanes, however, react with opening of the cyclopropane ring to give a homoallylic chloride.¹⁷⁹ When such reactions do occur, however, they take place by a nucleophilic addition mechanism, that is, initial attack is by X^- . This type of mechanism also occurs with Michael-type substrates $C=C-Z$,¹⁸⁰ There the orientation is always such that the halogen goes to the carbon that does not bear the Z , so the product is of the form $X-C-CH-Z$, even in the presence of free-radical initiators. Hydrogen iodine adds 1,4 to conjugated dienes in the gas phase by a pericyclic mechanism:¹⁸¹

HX can be added to ketenes¹⁸² to give acyl halides:

B. Oxygen on the Other Side

15-3 Hydration of Double bonds

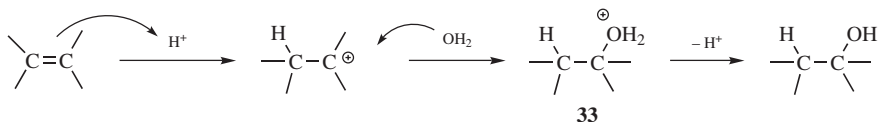

Hydro-hydroxy-addition

Double bonds can be hydrated by treatment with water and an acid catalyst. The most common catalyst is sulfuric acid, but other acids that have relatively non-nucleophilic counterions, such as nitric or perchloric can also be used. The mechanism is electrophilic and begins with attack of the π -bond on an acidic proton (see p. 1005). The resulting carbocation is then attacked by negative species, such as HSO_4^- (or similar counterion in the case of other acids), to give the initial product **32**, which can be isolated in some cases, but under the conditions of the

reaction, is usually hydrolyzed to the alcohol (**10-4**). However, the conjugate base of the acid is not the only possible species that attacks the initial carbocation. The attack can also be by water to form **33**.

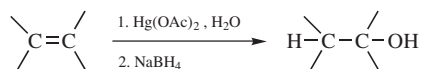

When the reaction proceeds by this pathway, **32** and similar intermediates are not involved and the mechanism is exactly (by the principle of microscopic reversibility) the reverse of E1 elimination of alcohols (**17-1**).¹⁸³ It is likely that the mechanism involves both pathways. *The initial carbocation occasionally rearranges to a more stable one.* For example, hydration of $\text{CH}_2=\text{CHCH}(\text{CH}_3)_2$ gives $\text{CH}_3\text{CH}_2\text{COH}(\text{CH}_3)_2$. With ordinary alkenes the addition predominantly follows Markovnikov's rule. Another method for Markovnikov addition of water consists of simultaneously adding an oxidizing agent (O_2) and a reducing agent (either Et_3SiH ¹⁸⁴ or a secondary alcohol, e.g., 2-propanol¹⁸⁵) to the alkene in the presence of a cobalt-complex catalyst. No rearrangement is observed with this

¹⁸³For discussions of the mechanism, see Vinnik, M.I.; Obratsov, P.A. *Russ. Chem. Rev.* **1990**, 59, 63; Liler, M. *Reaction Mechanisms in Sulphuric Acid*, Academic Press, NY, **1971**, pp. 210–225.

¹⁸⁵Inoki, S.; Kato, K.; Takai, T.; Isayama, S.; Yamada, T.; Mukaiyama, T. *Chem. Lett.* **1989**, 515.

method. The corresponding alkane and ketone are usually side products.

Alkenes can be hydrated quickly under mild conditions in high yields without rearrangement products by the use of *oxymercuration*¹⁸⁶ (addition of oxygen and mercury) followed by *in situ* treatment with sodium borohydride¹⁸⁷ (**12-24**). For example, 2-methyl-1-butene treated with mercuric acetate,¹⁸⁸ followed by NaBH₄, gave 2-methyl-2-butanol.

This method, which is applicable to mono-, di-, tri-, and tetraalkyl as well as phenyl-substituted alkenes, gives almost complete Markovnikov addition. Hydroxy, methoxy, acetoxy, halo, and other groups may be present in the substrate without, in general, causing difficulties.¹⁸⁹ When two double bonds are present in the same molecule, the use of ultrasound allows oxymercuration of the less-substituted one without affecting the other.¹⁹⁰ A related reaction treats an alkene with zinc borohydride on silica gel to give a 35:65 mixture of secondary:primary alcohols.¹⁹¹

Water can be added indirectly, with anti-Markovnikov orientation, by treatment of the alkene with a 1:1 mixture of PhCH₂NET₃⁺ BH₄⁻ and Me₃SiCl, followed by addition of an aqueous solution of K₂CO₃.¹⁹² Reaction of alkenes with Ti(BH₄)₃, and then aqueous K₂CO₃ also leads to the anti-Markovnikov alcohol.¹⁹³ Reaction of

terminal alkynes with water and ruthenium catalyst, followed by sequential treatment with long chain sulfates and then ammonium salts gave the aldehyde via anti-Markovnikov addition of water.¹⁹⁴ With substrates of the type $C=C-Z$ (Z is as defined on p. 1007) the product is almost always $HO-C-CH-Z$ and the mechanism is usually nucleophilic,¹⁹⁵ although electrophilic addition gives the same product¹⁹⁶ since a cation $CH-C-Z$ would be destabilized by the positive charges (full or partial) on two adjacent atoms. However, the α -hydroxy compound $HC-CH(OH)Z$, was obtained by treatment of the substrate with O_2 , $PhSiH_3$, and a manganese-complex catalyst.¹⁹⁷ When the substrate is of the type $RCH=CZZ'$, CZZ' , addition of water may result in cleavage of the adduct, to give an aldehyde and CH_2ZZ' , **34**.¹⁹⁸ The cleavage step is an example of **12-41**

For another method of anti-Markovnikov hydration, see hydroboration (**15-16**).

Alkenes react with PhO_2BH and a niobium catalyst, followed by oxidation with $NaOO^-$, to give the alcohol,¹⁹⁹ and Cp_2TiCl_4 can also be used.²⁰⁰ Reaction with $HSiCl_3$ and a chiral palladium catalyst, followed by reaction with KF and hydrogen peroxide, leads to the alcohol with high asymmetric induction.²⁰¹ Conjugated alkenes also react with $PhSiH_2$ and oxygen, with a manganese catalyst, to give an α -hydroxy ketone.²⁰² Alkenes react with molecular oxygen in the presence of a cobalt porphyrin catalyst, and reduction with $P(OMe)_3$ leads to the secondary alcohol.²⁰³ This procedure has also been used to hydrate conjugated dienes,²⁰⁴ although conjugated dienes are seldom hydrated.

The addition of water to enol ethers causes hydrolysis to aldehydes or ketones (**10-6**). Ketenes add water to give carboxylic acids ($R_2C=C=O \rightarrow R_2COOH$) in a reaction catalyzed by acids:²⁰⁵

OS IV, 555, 560; VI, 766. Also see, OS V, 818.

15-4 Hydration of Triple Bonds

Dihydro-oxo-biaddition

The hydration of triple bonds is generally carried out with mercuric ion salts (often the sulfate or acetate) as catalysts.²⁰⁶ Mercuric oxide in the presence of an acid is also a common reagent. Since the addition follows Markovnikov's rule, only acetylene gives an aldehyde. All other triple-bond compounds give ketones (for a method of reversing the orientation for terminal alkynes, see **15-16**). With alkynes of the form $RC\equiv CH$ methyl ketones are formed almost exclusively, but with $RC\equiv CR'$ both possible products are usually obtained. The reaction can be conveniently carried out with a catalyst prepared by impregnating mercuric oxide onto Nafion-H (a superacidic perfluorinated resinsulfonic acid, see p. 236).²⁰⁷ Terminal alkynes react with water at 200°C with microwave irradiation to give the corresponding methyl ketone.²⁰⁸ A gold catalyst was used in aqueous methanol with 50% sulfuric acid to convert terminal alkynes to the ketone.²⁰⁹ Conversion of phenyl acetylene to acetophenone was accomplished in water at 100°C with a catalytic amount of Tf_2NH (trifluoromethanesulfonimide).²¹⁰ In a modified reaction, internal alkynes were treated with 2-aminophenol in refluxing dioxane using a palladium catalyst to produce the corresponding ketone.²¹¹

Hydration of terminal alkynes can proceed with anti-Markovnikov addition. When 1-octyne was heated with water, isopropanol and a ruthenium catalyst, for example, the product was octanal.²¹² A similar reaction was reported in aqueous acetone using a ruthenium catalyst.²¹³ The presence of certain functionality can

influence the regioselectivity of hydration. 1-Seleno alkynes, such as $\text{PhSe-C}\equiv\text{C-Ph}$, react with tosic acid in dichloromethane to give a seleno ester $\text{PhSeC(=O)SH}_2\text{Ph}$ after treatment with water.²¹⁴

The first step of the mechanism is formation of a complex (**35**) (ions like Hg^{2+} form complexes with alkynes, p. 115). Water then attacks in an $\text{S}_{\text{N}}2$ -type process to give the intermediate **36**,

which loses a proton to give **37**. Hydrolysis of **37** (an example of **12-34**) gives the enol, which tautomerizes to the product. A spectrum of the enol was detected by flash photolysis when phenylacetylene was hydrated photolytically.²¹⁵

Carboxylic esters, thiol esters, and amides can be made, respectively, by acid-catalyzed hydration of acetylenic ethers, thioethers,²¹⁶ and ynamines, without a mercuric catalyst.²¹⁷

This is ordinary electrophilic addition, with rate-determining protonation as the first step.²¹⁸ Certain other alkynes have also been hydrated to ketones with strong acids in the absence of mercuric salts.²¹⁹ Simple alkynes can also be converted to ketones by heating with formic acid, without a catalyst.²²⁰ Lactones have been prepared from trimethylsilyl alkenes containing an hydroxyl unit elsewhere in the molecule, when reacted with molecular oxygen, CuCl_2 , and a palladium catalyst.²²¹

15-5 Addition of Alcohols and Phenols

Hydro-alkoxy-addition

The addition of alcohols and phenols to double bonds is catalyzed by acids or bases. When the reactions are acid catalyzed, the mechanism is electrophilic, with H^+ as the species attacked by the π -bond. The resulting carbocation combines with a molecule of alcohol to give an oxonium ion, **38**.

The addition, therefore, follows Markovnikov's rule. Primary alcohols give better results than secondary, and tertiary alcohols are very inactive. This is a convenient method for the preparation of tertiary ethers by the use of a suitable alkene, such as $\text{Me}_2\text{C}=\text{CH}_2$. Addition of alcohols to allylic systems can proceed with rearrangement, and the use of chiral additive can lead to asymmetric induction.²²³

Alcohols add intramolecularly to alkenes to generate cyclic ethers, often bearing a hydroxyl unit,²²⁴ but not always.²²⁵ Furan derivatives are available for alkene-ketones using CuCl_2 and a palladium catalyst,²²⁶ but chromium catalysts have been used for a similar purpose.²²⁷ A gold catalyst was used with conjugated ketones bearing an alkyne substituent to give fused-ring furans.²²⁸ Pyrone derivatives are available by the coupling of conjugated ketones bearing an alcohol unit, via an addition

elimination process mediated by a palladium catalyst.²²⁹ Intramolecular addition of alcohols to alkenes can be promoted by a palladium catalyst, with migration of the double bond in the final product.²³⁰ Rhenium compounds,²³¹ titanium compounds,²³² or platinum compounds²³³ facilitate this cyclization reaction to form functionalized tetrahydrofurans or tetrahydrofurans. Allylic alcohols have been converted to 2-bromo oxetanes using $\text{Br}(\text{collidine})_2^+ \text{PF}_6^-$.²³⁴ It is noted that the reaction of an alkene–alcohol and *N*-iodosuccinimide with a chiral titanium catalyst leads to a tetrahydrofuran with a pendant iodoalkyl group, with modest enantioselectivity.²³⁵

Allenes react with alcohols and allenic alcohols have been converted to tetrahydrofuran derivatives bearing a vinyl group at the α -position, using diphenyliodonium salts.²³⁶ In the presence of allylic bromide and a palladium catalyst, allenic alcohols lead to allylically substituted dihydrofurans.²³⁷ Intramolecular addition of alcohols to allenes leads to cyclic vinyl ethers.²³⁸ Alcohols add intramolecularly to a vinylidene dithiane under electrolytic conditions to form a tetrahydrofuran derivative with a pendant dithiane group.²³⁹

In the presence of other reagents, functionalized ethers can be formed. In methanol with an R–Se–Br reagent, alkenes are converted to selenoalkyl ethers (MeO–C–C–SeR).²⁴⁰

An interesting “double” addition was reported in which 2-(hydroxymethyl)phenol reacted with 2,3-dimethyl-2-butene in the presence of lithium perchlorate and Montmorillonite clay/water to give benzopyrans, but the reaction proceeded via an *O*-quinomethane generated *in situ*.²⁴¹

Alcohols add to alkynes under certain conditions to give vinyl ethers. In an excess of alcohol, and in the presence of a platinum catalyst, internal alkynes are converted to ketals.²⁴² The alcohol to alkyne addition reaction is quite useful for the preparation of heterocycles. Dihydrofurans,²⁴³ furans,²⁴⁴ benzofurans,²⁴⁵ and pyran

derivatives²⁴⁶ have been prepared using this approach. Tetrahydrofurans bearing an exocyclic double bond (vinylidene tetrahydrofurans) were prepared from alkynyl alcohols and a silver carbonate catalyst.²⁴⁷

For those substrates, more susceptible to nucleophilic attack, for example, polyhalo alkenes and alkenes of the type $C=C-Z$, it is better to carry out the reaction in basic solution, where the attacking species is RO^- .²⁴⁸ The reactions with $C=C-Z$ are of the Michael type, and OR goes to the side away from the Z.²⁴⁹ Since triple bonds are more susceptible to nucleophilic attack than double bonds, it might be expected that bases would catalyze addition to triple bonds particularly well. This is the case, and enol ethers and acetals can be produced by this reaction.²⁵⁰ Because enol ethers are more susceptible than triple bonds to electrophilic attack, the addition of alcohols to enol ethers can also be catalyzed by acids.²⁵¹ One utilization of this reaction involves the compound dihydropyran

(**39**), which is often used to protect the OH groups of primary and secondary alcohols and phenols.²⁵³ The tetrahydropyranyl acetal formed by this reaction (**40**) is stable to bases, Grignard reagents, $LiAlH_4$, and oxidizing agents, any of which can be used to react with functional groups located within the R group. When the reactions are completed, **40** is easily cleaved by treatment with dilute acids (**10-6**). The addition of alcohols to enol ethers is also catalyzed by $CoCl_2$.²⁵⁴

Conjugate addition of alcohols to conjugated esters, using ceric ammonium nitrate and LiBr, gave the corresponding α -bromo- β -alkoxy ester.²⁵⁵

In base-catalyzed addition to triple bonds, the rate falls in going from a primary to a tertiary alcohol, and phenols require more severe conditions. Other catalysts, namely, BF_3 and mercuric salts, have also been used in addition of ROH to triple bonds.

Alcohols can be added to certain double-bond compounds (cyclohexenes, cycloheptenes) photochemically²⁵⁶ in the presence of a photosensitizer such as benzene. The mechanism is electrophilic and Markovnikov orientation is found. The alkenes react in their first excited triplet states.²⁵⁷

The oxymercuration–demercuration procedure mentioned in **15-3** can be adapted to the preparation of ethers (Markovnikov orientation) if the oxymercuration is carried out in an alcohol ROH as solvent,²⁵⁸ for example 2-methyl-1-butene in ethanol gives EtMe₂COEt.²⁵⁹ Primary alcohols give good yields when mercuric acetate is used, but for secondary and tertiary alcohols it is necessary to use mercuric trifluoroacetate.²⁶⁰ However, even this reagent fails where the product would be a ditertiary ether. It is possible to combine the alcohol reactant with another reagent. The reaction of an alkene with iodine and allyl alcohol, in the presence of HgO, gave the *vic*-iodo ether.²⁶¹ Alkene-alcohols react with mercuric trifluoroacetate and the aq. KBr (with LiBH₄/BEt₃) to give a derivative bearing an iodoalkyl substituent, –O–C–CH(I)R.²⁶² Alkynes generally give acetals. If the oxymercuration is carried out in the presence of a hydroperoxide instead of an alcohol, the product (after demercuration with NaBH₄) is an alkyl peroxide (peroxy-mercuration).²⁶³ This can be done intramolecularly.²⁶⁴

Both alcohols and phenols add to ketenes to give carboxylic esters [R₂C=C=O + ROH → R₂CHCO₂R].²⁶⁵ This has been done intramolecularly (with the ketene end of the molecule generated and used *in situ*) to form medium- and large-ring lactones.²⁶⁶ In the presence of a strong acid, ketene reacts with aldehydes or ketones (in their enol forms) to give enol acetates. 1,4-Asymmetric induction is possible when chiral alcohols add to ketenes.²⁶⁷

15-6 Addition of Carboxylic Acids to Form Esters

Hydro-acyloxy-addition

Carboxylic esters are produced by the addition of carboxylic acids to alkenes, a reaction that is usually acid-catalyzed (by proton or Lewis acids²⁶⁸) and similar in mechanism to **15-5**. Since Markovnikov's rule is followed, hard-to-get esters of tertiary alcohols can be prepared from alkenes of the form $\text{R}_2\text{C}=\text{CHR}$.²⁶⁹ A combination of V_2O_5 and trifluoroacetic acid converts alkenes to trifluoroacetate esters.²⁷⁰ When a carboxylic acid that contains a double bond in the chain is treated with a strong acid, the addition occurs internally and the product is a γ - and/or a δ -lactone, regardless of the original position of the double bond in the chain, since strong acids catalyze double-bond shifts (**12-2**).²⁷¹ The double bond always migrates (also see, **15-1**) to a position favorable for the reaction, whether this has to be toward or away from the carboxyl group. The use of a chiral *Cinchonidine* alkaloid additive leads to lactone formation with modest enantioselectivity.²⁷² In the presence of diphenyl diselenide and DDQ, alkene carboxylic acids react to form the lactone with a phenylselenomethyl group (PhSeCH_2-) at C-5.²⁷³ Carboxylic esters have also been prepared by the acyloxymercuration-demercuration of alkenes (similar to the procedures mentioned in **15-3** and **15-4**).²⁷⁴ Conjugated esters has been converted to β -lactones with photolysis and added tributyltin hydride, radical cyclization conditions (**15-30**).²⁷⁵ Addition of carboxylic acids to alkenes to form esters or lactones is catalyzed by palladium compounds.²⁷⁶ Thallium acetate also promotes this cyclization reaction.²⁷⁷

Triple bonds can give enol esters²⁷⁸ or acylals when treated with carboxylic acids. Mercuric salts are usually catalysts,²⁷⁹ and vinylic mercury compounds

Terminal alkynes $\text{RC}\equiv\text{CH}$ react with CO_2 , a secondary amine $\text{R}'_2\text{NH}$, and a ruthenium complex catalyst, to give enol carbamates $\text{RCH}=\text{CHOC}(=\text{O})\text{NR}$.²⁸¹ This reaction has also been performed intramolecularly, to produce unsaturated lactones.²⁸² Cyclic unsaturated lactones (internal vinyl esters) have been generated from alkyne-carboxylic acids using a palladium catalyst²⁸³ or a ruthenium catalyst.²⁸⁴ Carboxylic esters can also be obtained by the addition to alkenes of diacyl peroxides.²⁸⁵ These reactions are catalyzed by copper and are free-radical processes.

Allene carboxylic acids have been cyclized to butenolides with copper(II) chloride.²⁸⁶ Allene esters were converted to butenolides by treatment with acetic acid and LiBr .²⁸⁷ Cyclic carbonates can be prepared from allene alcohols using carbon dioxide and a palladium catalyst, and the reaction was accompanied by arylation when iodobenzene was added.²⁸⁸ Diene carboxylic acids have been cyclized using acetic acid and a palladium catalyst to form lactones that have an allylic acetate elsewhere in the molecule.²⁸⁹ With ketenes, carboxylic acids give anhydrides²⁹⁰ and acetic anhydride is prepared industrially in this manner $[\text{CH}_2=\text{C}=\text{O} + \text{MeCO}_2\text{H} \rightarrow (\text{MeC}=\text{O})_2\text{O}]$.

Sulfonic acids add to alkenes and alkynes. The reaction of an alkyne with *para*-toluenesulfonic acid and treatment with silica gives the vinyl sulfonate ($C=C-OSO_2Tol$).²⁹¹ Cyclic sulfonates can be generated by the reaction of an allylic sulfonate salt ($C=C-C-OSO_3^-$) with silver nitrate in acetonitrile containing an excess of bromine and a catalytic amount of water.²⁹² Sultones are formed when alkenes react with PhIO and two equivalents of Me_2SiSO_3Cl .²⁹³

C. Sulfur on the Other Side

15-7 Addition of H₂S and Thiols

Hydro-alkylthio-addition

Hydrogen sulfide (H₂S) and thiols add to alkenes to give alkyl thiols or sulfides by electrophilic, nucleophilic, or free-radical mechanisms.²⁹⁴ In the absence of initiators, the addition to simple alkenes is by an electrophilic mechanism, similar to that in 15-5, and Markovnikov's rule is followed. However, this reaction is usually very slow and often cannot be done or requires very severe conditions unless a proton or Lewis acid catalyst is used. For example, the reaction can be performed in concentrated H₂SO₄²⁹⁵ or together with AlCl₃.²⁹⁶ In the presence of free-radical initiators, H₂S and thiols add to double and triple bonds by a free-radical mechanism and the orientation is anti-Markovnikov.²⁹⁷ The addition of thiophenol to an alkene with a zeolite also leads to the anti-Markovnikov sulfide.²⁹⁸ Additives can influence the regioselectivity. Styrene reacts with thiophenol to give primarily the anti-Markovnikov product, whereas addition of thiophenol in the presence of Montmorillonite K10 clay gives primarily the Markovnikov addition product.²⁹⁹ In fact, the orientation can be used as a diagnostic tool to indicate which mechanism is operating. Free-radical addition can be done with H₂S, RSH (R may be primary,

secondary, or tertiary), ArSH, or RCOSH.³⁰⁰ The R group may contain various functional groups. The alkenes may be terminal, internal, contain branching, be cyclic, and have various functional groups including OH, COOH, COOR, NO₂, RSO₂, and so on. Addition of Ph₃SiSH to terminal alkenes under radical conditions also leads to the primary thiol.³⁰¹

Alkynes react with thiols to give vinyl sulfides. With alkynes it is possible to add 1 or 2 equivalents of RSH, giving a vinyl sulfide³⁰² or a dithioacetal, respectively. Alternative preparations are available, as in the reaction of a terminal alkyne with Cp₂Zr(H)Cl followed by PhSCl to give the vinyl sulfide with the SPh unit at the less substituted position (PhCH=CHSPh).³⁰³ The intramolecular addition of a thiol to an ene-yne, with a palladium catalyst, leads to substituted thiophene derivatives.³⁰⁴

The fundamental addition reaction can be modified by the use of transition metals and different reagents. Alkenes react with diphenyl disulfide in the presence of GaCl₃ to give the product with two phenylthio units, PhS-C-C-SPh.³⁰⁵ The reaction of an alkyne with diphenyl disulfide and a palladium catalyst leads to the bis-vinyl sulfide, PhS-C=C-SPh.³⁰⁶

When thiols are added to substrates susceptible to nucleophilic attack, bases catalyze the reaction and the mechanism is nucleophilic. These substrates may be of the Michael type³⁰⁷ or may be polyhalo alkenes or alkynes.²⁵⁰ As with the free-radical mechanism, alkynes can give either vinylic thioethers or dithioacetals:

Thiols add to alkenes under photochemical conditions to form thioethers, and the reaction can be done intramolecularly to give cyclic thioethers.³⁰⁸ Thiols also add to alkynes and with a palladium catalyst, vinyl sulfides can be formed.³⁰⁹ Thio-carbonates function as thiol surrogates, converting alkenes to alkyl thiol in the presence of TiCl₄; and CuO.³¹⁰

By any mechanism, the initial product of addition of H₂S to a double bond is a thiol, which is capable of adding to a second molecule of alkene, so that sulfides

D. Nitrogen or Phosphorus on the Other Side

15-8 Addition of Ammonia and Amines, Phosphines, and Related Compounds

Hydro-amino-addition

Hydro-phosphino-addition

Ammonia and primary and secondary amines add to alkenes *that are susceptible* to nucleophilic attack.³¹⁴ Ammonia and amines are much weaker acids than water, alcohols, and thiols (see **15-3**, **15-5**, **15-7**) and since acids turn NH_3 into the weak

³¹¹For an example, see Blake, A.J.; Friend, C.L.; Outram, R.J.; Simpkins, N.S.; Whitehead, A.J. *Tetrahedron Lett.* **2001**, 42, 2877.

acid, the ammonium ion NH_4^+ , this reaction does not occur by an electrophilic mechanism. The reaction tends to give very low yields, if any, with ordinary alkenes, unless extreme conditions are used (e.g., 178–200°C, 800–1000 atm, and the presence of metallic Na, for the reaction between NH_3 and ethylene³¹⁵). Amine alkenes give cyclic amines as the major product, in good yield, when treated with *n*-butyllithium.³¹⁶ Ammonia gives three possible products, since the initial product is a primary amine, which may add to a second molecule of alkene, and so on. Similarly, primary amines give both secondary and tertiary products. In practice it is usually possible to control which product predominates. The mechanism is nearly always nucleophilic, and the reaction is generally performed on polyhalo alkenes³¹⁷ and alkynes.³¹⁸ Ammonia adds to alkenes photochemically.³¹⁹ Reaction of a secondary amine with butyllithium generates an amide base, which reacts with alkenes to give alkyl amines,³²⁰ and can add intramolecularly to an alkene to form a pyrrolidine.³²¹ Pyrroles can be generated in this manner.³²² *N*-Chloroamines add to alkenes intramolecularly to give β -chloropyrrolidines.³²³

Conjugated carbonyl compounds react via conjugate addition with amines to give β -amino derivatives (see **15-31**)³²⁴ As expected, on Michael-type substrates the nitrogen goes to the carbon that does not carry the Z. With substrates of the form $\text{RCH}=\text{CZZ}'$, the same type of cleavage of the adduct can take place as in **15-3**.³²⁵

There are many examples of transition catalyzed addition of nitrogen compounds to alkenes, alkynes,³²⁶ and so on. Secondary amines can be added to certain nonactivated alkenes if palladium(II) complexes are used as catalysts.³²⁷

The complexation lowers the electron density of the double bond, facilitating nucleophilic attack.³²⁸ Markovnikov orientation is observed and the addition is anti.³²⁹ Molybdenum,³³⁰ titanium,³³¹ Yttrium,³³² and rhodium compounds³³³ have been used in the addition of amines to alkenes. An intramolecular addition of an amine unit to an alkene to form a pyrrolidine was reported using a palladium catalyst,³³⁴ a lanthanide reagent,³³⁵ or an yttrium reagent.³³⁶ Aniline reacts with dienes and a palladium catalyst to give allylic amines.³³⁷ Diene amines react with samarium catalysts to give 2-alkenyl pyrrolidines.³³⁸ Addition of secondary amines to dihydropyrans using a palladium catalyst gave the corresponding aminal (an α -amino ether).³³⁹ Reduction of nitro compounds in the presence of rhodium catalysts, in the presence of alkenes, CO and H₂, leads to an amine unit adding to the alkene moiety.³⁴⁰ Secondary amines react with alkenes to give the alkyl amine using a rhodium catalyst in a CO/H₂ atmosphere,³⁴¹ but modification of the chromium catalyst and conditions led to an enamine.³⁴² Note that the reaction of an alkene and a secondary amine with a rhodium catalyst can also give an enamine.³⁴³

Other nitrogen compounds, among them hydroxylamine and hydroxylamines,³⁴⁴ hydrazines, and amides (**15-9**), also add to alkenes. Azodicarboxylates (Boc-N=N-Boc) react with alkenes, in the presence of PhSiH₃ and a cobalt catalyst, to give

alkylhydrazides [RN(Boc)—NHBoc].³⁴⁵ Even with amines, basic catalysts are sometimes used, so that RNH[−] or R₂N[−] is the actual nucleophile. Tertiary amines (except those that are too bulky) add to Michael-type substrates in a reaction that is catalyzed by acids like HCl or HNO₃ to give the corresponding quaternary ammonium salts.³⁴⁶

The tertiary amine can be aliphatic, cycloalkyl, or heterocyclic (including pyridine). The reaction of NaOH with an amine containing two distal alkene units, followed by addition of a neodymium catalyst leads to a bicyclic amine.³⁴⁷

Primary amines add to triple bonds³⁴⁸ to give enamines that have a hydrogen on the nitrogen and (analogously to enols) tautomerize to the more stable imines, **41**.³⁴⁹

The reaction has been done with a palladium catalyst,³⁵⁰ a titanium catalyst,³⁵¹ a tantalum catalyst,³⁵² and with a gold catalyst.³⁵³ An intramolecular addition of amines to an alkyne unit in the presence of a palladium catalyst generated heterocyclic or cyclic amine compounds.³⁵⁴ The titanium catalyzed addition of primary

amines to alkynes give the enamine, which can be hydrogenated (**15-11**) to give the corresponding amine.³⁵⁵ A variation treats an alkynyl imine with CuI to form pyrroles.³⁵⁶ *N,N*-Diphenylhydrazine reacts with diphenyl acetylene and a titanium catalyst to give indole derivatives.³⁵⁷ Treatment of an imine of 2-alkynyl benzaldehyde with iodide gave a functionalized isoquinoline.³⁵⁸ When ammonia is used instead of a primary amine, the corresponding $\text{RH}_2\text{C}-\overset{\text{NH}}{\parallel}{\text{C}}-\text{R}'$ is not stable enough for isolation, but polymerizes. Ammonia and primary amines (aliphatic and aromatic) add to conjugated diynes to give pyrroles, **42**.³⁵⁹ A similar preparation of pyrroles was reported by heating non-conjugated diynes with aniline and a titanium catalyst.³⁶⁰ This is not 1,4-addition, but 1,2-addition twice. Conjugated ene-yne containing an amino group also give pyrroles with a palladium catalyst.³⁶¹

Allenes are reaction partners,³⁶² and amines add to allenes in the presence of a catalytic amount of CuBr³⁶³ or palladium compounds.³⁶⁴ Intramolecular reaction of allene amines lead to dihydropyrroles, using a gold catalyst.³⁶⁵

Treatment of an allene amine with a ruthenium catalyst, 10% of TiCl₄ and methyl vinyl ketone to give a product of amine addition followed by Michael addition, a pyrrolidine derivative with a pendant alkenyl ketone unit.³⁶⁶ Cyclic imines can be prepared from allene amines using a titanium catalyst.³⁶⁷

Primary and secondary amines add to ketenes to give, respectively, *N*-substituted and *N,N*-disubstituted amides:³⁶⁸ and to ketenimines to give amidines, **43**.³⁶⁹

NH₃ can be added to double bonds (even ordinary double bonds) in an indirect manner by the use of hydroboration (**15-16**) followed by treatment with NH₂Cl or NH₂OSO₂OH (**12-32**). This produces a primary amine with anti-Markovnikov orientation. An indirect way of adding a primary or secondary amine to a double bond consists of aminomercuration followed by reduction (see **15-3** for the analogous oxymercuration–demercuration procedure), to give amine **45**.³⁷⁰

The addition of a secondary amine (shown above) produces a tertiary amine, while addition of a primary amine gives a secondary amine. The overall orientation follows Markovnikov's rule. For conversion of **44** to other products, see **15-53**.

Phosphines add to alkenes to give alkyl phosphines and to alkynes to give vinyl phosphines. In the presence of an ytterbium (Yb) catalyst, diphenylphosphine added to diphenyl acetylene to give the corresponding vinyl phosphine.³⁷¹ A palladium catalyst was used for the addition *o*-diphenylphosphine to terminal alkynes, giving the anti-Markovnikov vinyl phosphine but a nickel catalyst led to the Markovnikov vinyl phosphine.³⁷² Alkenes also react with diarylphosphines

15-9 Addition of Amides

Hydro-amido-addition

Under certain conditions, amides can add directly to alkenes to form *N*-alkylated amides. Sulfonamides react in a similar manner. 3-Pentenamide was cyclized to 5-methyl-2-pyrrolidinone by treatment with trifluorosulfonic acid.³⁸³ Acyl hydrazine derivatives also cyclized in the presence of hypervalent iodine reagents to give lactams.³⁸⁴ When a carbamate was treated with Bu_3SnH , and AIBN, addition to an alkene led to a bicyclic lactam.³⁸⁵

The reaction can be done intramolecularly. *N*-Benzyl pent-4-ynamide reacted with tetrabutylammonium fluoride to an alkylidene lactam.³⁸⁶ Similar addition of a tosylamide-alkene, with a palladium catalyst, led to a vinyl *N*-tosyl pyrrolidine.³⁸⁷ Similar cyclization reactions occur with tosylamide-alkynes.³⁸⁸

Treatment of triflamide alkenes with triflic acid gives the corresponding *N*-triflyl cyclic amine.³⁸⁹ Using an alkene halide and an *N*-chlorosulfonamide, an amide is generated *in situ*, and addition to the alkene gives a pyrrolidine derivative.³⁹⁰ *N*-Bromocarbamates also add to alkenes, in the presence of $\text{BF}_3 \cdot \text{OEt}_2$ to give a *vic*-bromo *N*-Boc amine.³⁹¹ The titanium catalyzed reaction of alkenyl *N*-tosylamines give *N*-tosyl cyclic amines.³⁹²

Alkynes and allenes also react with amides. Phenylthiomethyl alkynes were converted to *N*-Boc-*N*-phenylthio allenes with Boc azide and an iron catalyst.³⁹³ The palladium-catalyzed reaction of an allene amide, with iodobenzene, leads to *N*-sulfonyl aziridines having an allylic group at C1.³⁹⁴ Other allene *N*-tosylamines similarly give *N*-tosyl tetrahydropyridines.³⁹⁵

Imides can also add to alkenes or alkynes. Ethyl 2-propynoate reacted with phthalimide, in the presence of a palladium catalyst, to give ethyl 2-phthalimido-2-propenoate.³⁹⁶

15-10 Addition of Hydrazoic Acid

Hydro-azido-addition

Hydrazoic acid (HN_3) can be added to certain Michael-type substrates (*Z* is as defined on p. 1007) to give β -azido compounds.³⁹⁷ The reaction apparently fails if R

is phenyl. The HN_3 also adds to enol ethers $\text{CH}_2=\text{CHOR}$ to give $\text{CH}_3-\text{CH}(\text{OR})\text{N}_3$, and to silyl enol ethers,³⁹⁸ but it does not add to ordinary alkenes unless a Lewis acid catalyst, such as TiCl_4 , is used, in which case good yields of azide can be obtained.³⁹⁸ Hydrazoic acid can also be added indirectly to ordinary alkenes by azidomercuration, followed by demercuration,³⁹⁹ analogous to the similar procedures

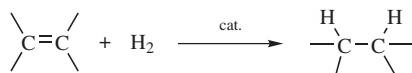

mentioned in **15-3**, **15-5**, **15-6**, and **15-8**. The method can be applied to terminal alkenes or strained cycloalkenes (e.g., norbornene) but fails for unstrained internal alkenes.

E. Hydrogen on Both Sides

15-11 Hydrogenation of Double and Triple Bonds⁴⁰⁰

Dihydro-addition

Most carbon–carbon double bonds, whether substituted by electron-donating or electron-withdrawing substituents, can be catalytically hydrogenated, usually in quantitative or near-quantitative yields.⁴⁰¹ Almost all known alkenes added hydrogen at temperatures between 0 and 275°C. The catalysts used can be divided into

two broad classes, both of which mainly consist of transition metals and their compounds: (1) catalysts insoluble in the reaction medium (*heterogeneous catalysts*). Among the most effective are Raney nickel,⁴⁰² palladium-on-charcoal (perhaps the most common),⁴⁰³ NaBH₄-reduced nickel⁴⁰⁴ (also called nickel boride), platinum metal or its oxide, rhodium, ruthenium, and zinc oxide.⁴⁰⁵ (2) Catalysts soluble in the reaction medium (*homogeneous catalysts*).⁴⁰⁶ An important example is chlorotris(triphenylphosphine)rhodium, RhCl(Ph₃P)₃,⁴⁰⁷ (**100**, *Wilkinson's catalyst*),⁴⁰⁸ which catalyzes the hydrogenation of many alkenyl compounds without disturbing such groups as COOR, NO₂, CN, or COR present in the same molecule.⁴⁰⁹ Even unsaturated aldehydes can be reduced to saturated aldehydes,⁴¹⁰ although in this case decarbonylation (**14-32**) may be a side reaction. In general, for catalytic hydrogenation, many functional groups may be present in the molecule, for example, OH, COOH, NR₂ including NH₂, N(R)COR' including carbamates,⁴¹¹ CHO, COR, COOR, or CN. Vinyl esters can be hydrogenated using homogeneous rhodium catalyst.⁴¹² Enamides are hydrogenated, with excellent enantioselectivity, using chiral rhodium catalysts.⁴¹³ Some of these groups are also susceptible to catalytic reduction, but it is usually possible to find conditions

⁴⁰²For a review of Raney nickel, see Pizey, J.S. *Synthetic Reagents*, Vol. 2, Wiley, NY, **1974**, pp. 175–311. Double bonds have been reduced with Raney nickel alone; with no added H₂. The hydrogen normally present in this reagent was sufficient: Pojer, P.M. *Chem. Ind. (London)* **1986**, 177.

under which double bonds can be reduced selectively⁴¹⁴ (see Table 19.2). Controlling the solvent allows catalytic hydrogenation of an alkene in the presence of an aromatic nitro group.⁴¹⁵

Among other homogeneous catalysts are chlorotris(triphenylphosphine)hydridoruthenium(II), $(\text{Ph}_3\text{P})_3\text{RuClH}$,⁴¹⁶ which is specific for terminal double bonds (other double bonds are hydrogenated slowly or not at all), and pentacyanocobaltate(II), $\text{Co}(\text{CN})_5^{3-}$, which is effective for double and triple bonds only when they are part of conjugated systems⁴¹⁷ (the conjugation may be with $\text{C}=\text{C}$, $\text{C}=\text{O}$, or an aromatic ring). Colloidal palladium has also been used as a catalyst,⁴¹⁸ and a polymer bound ruthenium catalyst has also been used.⁴¹⁹ A polymer incarcerated palladium catalyst gave the hydrogenated product in quantitative yields.⁴²⁰ Rhodium on mesoporous silica can be used to hydrogenate alkenes.⁴²¹ A nanoparticulate palladium catalyst in an ionic liquid has been used for the hydrogenation of alkenes.⁴²²

Homogeneous catalysts often have the advantages of better catalyst reproducibility and better selectivity. They are also less susceptible to catalyst poisoning⁴²³ (heterogeneous catalysts are usually poisoned by small amounts of sulfur, often found in rubber stoppers, or by sulfur-containing compounds, such as thiols and sulfides).⁴²⁴ On the other hand, heterogeneous catalysts are usually easier to separate from the reaction mixture.

Unfunctionalized alkenes are hydrogenated with good diastereoselectivity and enantioselectivity using various metal catalysts and chiral ligands.⁴²⁵ Soluble, chiral homogeneous catalysts are usually the best choice, especially for alkenes. The transition-metal catalyst (rhodium and ruthenium are probably the most common) is usually prepared with suitable chiral ligands prior to addition to the reaction, or an achiral catalyst, such as Wilkinson's catalyst, **100**: $\text{RhCl}(\text{Ph}_3\text{P})_3$, is added along with a chiral ligand. The chiral ligand is typically a phosphine. In one case, the phosphorous may be chiral, as in **101** (called R-camp),⁴²⁶ but pyramidal inversion at elevated temperatures (see p. 142) limits the utility of such ligands. The alternative is to prepare a phosphine containing a chiral carbon, and bis(phosphines), such as **102** (called dipamp)⁴²⁷ are the most common. There are many variations of chiral bis(phosphine) ligands. Mono-phosphine ligands have also been used.⁴²⁸ Titanocenes⁴²⁹ with chiral cyclopentadienyl ligands have given enantioselective hydrogenation of unfunctionalized alkenes, such as 2-phenyl-1-butene.⁴³⁰ Chiral poisoning has been used as a strategy for asymmetric catalysis.⁴³¹

Hydrogenations in most cases are carried out at room temperature and just above atmospheric pressure, but some double bonds are more resistant and require higher temperatures and pressures. The resistance is usually a function of increasing substitution and is presumably caused by steric factors. Trisubstituted double bonds require, say, 25°C and 100 atm, while tetrasubstituted double bonds may require 275°C and 1000 atm. Among

**103**

the double bonds most difficult to hydrogenate or which cannot be hydrogenated at all are those common to two rings, as in steroid **103**. Hydrogenations, even at about atmospheric pressure, are ordinarily performed in a special hydrogenator, but this is

not always necessary. Both the catalyst and the hydrogen can be generated *in situ*, by treatment of H_2PtCl_6 or RhCl_3 with NaBH_4 ;⁴³² ordinary glassware can then be used. The great variety of catalysts available often allows an investigator to find one that is highly selective. For example, the catalyst Pd(salen) encapsulated in zeolites permitted the catalytic hydrogenation of 1-hexene in the presence of cyclohexene.⁴³³ It has been shown that the pressure of the reaction can influence enantioselectivity in asymmetric catalytic hydrogenations.⁴³⁴

Triple bonds can be reduced, either by catalytic hydrogenation or by the other methods mentioned in the following two sections. The comparative reactivity of triple and double bonds depends on the catalyst. With most catalysts (e.g., Pd), triple bonds are hydrogenated more easily, and therefore it is possible to add just 1 equivalent of hydrogen and reduce a triple bond to a double bond (usually a stereoselective syn addition) or to reduce a triple bond without affecting a double bond present in the same molecule.⁴³⁵ A particularly good catalyst for this purpose is the Lindlar catalyst (Pd-CaCO₃-PbO).⁴³⁶ An alternative catalyst used for selective hydrogenation to cis-alkenes is palladium on barium sulfate (BaSO₄) catalyst, poisoned with quinoline⁴³⁷ (sometimes called the *Rosenmund catalyst*). Palladium on calcium carbonate in polyethylene glycol (PEG) has also been used as a recyclable catalyst system.⁴³⁸ Hydrogenation using a palladium catalyst on pumice was shown to give the cis-alkene with excellent selectivity.⁴³⁹ Hydrogenation of a C≡C unit occurs in the presence of other functional groups, including NR₂ including NH₂,⁴⁴⁰ and sulfonyl.⁴⁴¹

Conjugated dienes can add hydrogen by 1,2- or 1,4-addition. Selective 1,4-addition can be achieved by hydrogenation in the presence of carbon monoxide, with bis(cyclopentadienyl)chromium as catalyst.⁴⁴² With allenes⁴⁴³ catalytic hydrogenation usually reduces both double bonds.

Most catalytic reductions of double or triple bonds, whether heterogeneous or homogeneous, have been shown to be syn, with the hydrogens entering from the less-hindered side of the molecule.⁴⁴⁴ Stereospecificity can be investigated only for tetrasubstituted alkenes (except when the reagent is D₂), which are the hardest to hydrogenate, but the results of these investigations show that the addition is usually 80–100% syn, although some of the anti addition product is normally also found and in some cases predominates. Catalytic hydrogenation of alkynes is nearly always stereoselective, giving the cis alkene (usually at least 80%), even when it is thermodynamically less stable. For example, **104** gave **105**, even although the steric hindrance is such that a planar molecule is impossible.⁴⁴⁵ This is thus a useful method for preparing cis alkenes.⁴⁴⁶ However, when

steric hindrance is too great, the trans alkene may be formed. One factor that complicates the study of the stereochemistry of heterogeneous catalytic hydrogenation is that exchange of hydrogens takes place, as can be shown by hydrogenation with deuterium.⁴⁴⁷ Thus deuterogenation of ethylene produced all the possible deuterated ethylenes and ethanes (even C₂H₆), as well as HD.⁴⁴⁸ With 2-butene, it was found that double-bond migration, cis–trans isomerization, and even exchange of hydrogen with groups not on the double bond could occur; for example, C₄H₂D₈ and C₄HD₉ were detected on treatment of *cis*-2-butene with deuterium and a catalyst.⁴⁴⁹ Indeed, *alkanes* have been found to exchange with deuterium over a catalyst,⁴⁵⁰ and even without deuterium, for example, CH₄ + CD₄ → CHD₃ + CH₃D

D in the gas phase, with a catalyst. All this makes it difficult to investigate the stereochemistry of heterogeneous catalytic hydrogenation.

The mechanism of the heterogeneous catalytic hydrogenation of double bonds is not thoroughly understood because it is a very difficult reaction to study.⁴⁵¹ Because the reaction is heterogeneous, kinetic data, although easy to obtain (measurement of decreasing hydrogen pressure), are difficult to interpret. Furthermore, there are the difficulties caused by the aforementioned hydrogen exchange. The currently accepted mechanism for the common two-phase reaction was originally proposed in 1934.⁴⁵² According to this, the alkene is adsorbed onto the surface of the metal, although the nature of the actual bonding is unknown,⁴⁵³ despite many attempts to elucidate it.⁴⁵⁴ In the 1934 work, the metallic site was indicated by an asterisk, but here we use . For steric reasons it is apparent that adsorption of the alkene takes place with its less-hindered side attached to the catalyst surface, probably as an η^2 complex (see p. 116). The fact that addition of hydrogen is generally also from the less-hindered side indicates that the hydrogen too is probably adsorbed on the catalyst surface before it reacts with the alkene. It is likely that as the H_2 molecule is adsorbed on (coordinated to) the metal catalyst, cleavage occurs to give η^1 -coordinated hydrogen atoms (see p. \$\$\$). Note that this model suggests a single metal particle for coordination of the alkene and the hydrogen atoms, but the hydrogen atoms and the alkene could be coordinated to different metal particles. It has been shown that platinum catalyzes homolytic cleavage of hydrogen molecules.⁴⁵⁵ In the second step, one of the adsorbed (η^1 -coordinated) hydrogen atoms becomes attached to a carbon atom, creating in effect, an alkyl radical (which is still bound to the catalyst although only by one bond, probably η^1 -coordination). Transfer of a hydrogen atom to carbon opens a site on the metal catalyst for coordination to additional hydrogen atoms. Finally, another hydrogen atom (not necessarily the one originally connected to the first hydrogen) combines with the radical

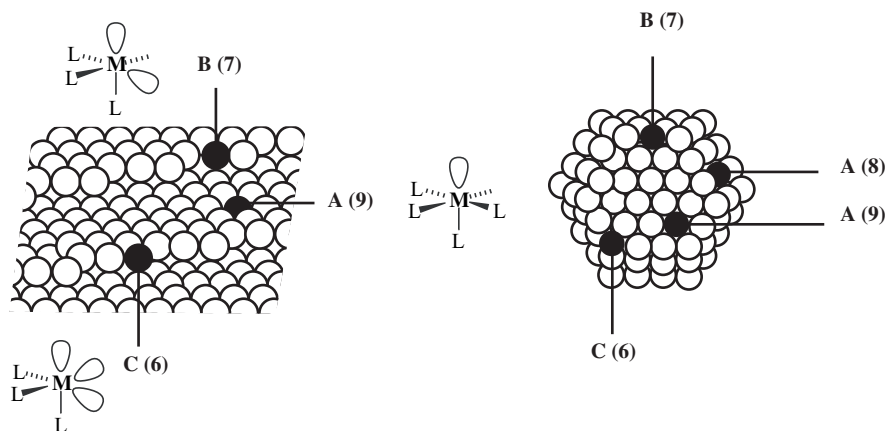

Fig. 15.1. The principal surface and particle sites for heterogeneous catalysts.

to give the reaction product, freed from the catalyst surface, and the metal catalyst that is now available for coordination of additional hydrogen atoms and/or alkenes. All the various side reactions, including hydrogen exchange and isomerism, can be explained by this type of process.⁴⁵⁶ Although this mechanism is satisfactory as far as it goes,⁴⁵⁷ there are still questions it does not answer, among them questions⁴⁵⁸ involving the nature of the asterisk, the nature of the bonding, and the differences caused by the differing nature of each catalyst.⁴⁵⁹

Heterogeneous catalysis occurs at the surface of the metal catalyst, and there are different types of metal particles on the surface. Maier suggested the presence of **terrace-**, **step-**, and **kink-**type atoms (in Fig. 6.1)⁴⁶⁰ on the surface of a heterogeneous catalyst. These terms refer to different atom types, characterized by the number of nearest neighbors,⁴⁶⁰ which correspond to different transition-metal fragments, as well as to different coordination states of that metal.⁴⁶¹ A terrace-type atom (A in Fig. 15.1) typically has eight or nine neighbors and corresponds to a geometry shown for the ML_5 particle. The step type of atom (B) usually has seven neighbors and can be correlated with the geometry shown for the ML_4

⁴⁵⁶Smith, G.V.; Burwell Jr., R.L. *J. Am. Chem. Soc.* **1962**, *84*, 925.

⁴⁵⁷A different mechanism has been proposed by Zaera, F.; Somorjai, G.A. *J. Am. Chem. Soc.* **1984**, *106*, 2288, but there is evidence against it: Beebe, Jr., T.P.; Yates Jr., J.T. *J. Am. Chem. Soc.* **1986**, *108*, 663. See also, Thomson, S.J.; Webb, G. *J. Chem. Soc., Chem. Commun.* **1976**, 526.

particle. Finally, the kink-type atom (C) has six neighbors and corresponds to geometry shown for the ML_3 particle. In general, as the particle size increases, the relative concentration of terrace atoms will increase, whereas small particle size favors the kink type of surface atoms.

The mechanism of homogeneous hydrogenation⁴⁶² catalyzed by $RhCl(Ph_3P)_3$ (**100**, Wilkinson's catalyst)⁴⁶³ involves reaction of the catalyst with hydrogen to form a metal hydride $(PPh_3)_2RhH_2Cl$ (**106**).⁴⁶⁴ Replacement of a triphenylphosphine ligand with two atoms of hydrogen constitutes an oxidative addition.

After coordination of the alkene to form **107**, transfer of hydrogen to carbon is an insertion process, presumably generating **109**, and a second insertion liberates the hydrogenated compound, and rhodium species **108**, which adds hydrogen by oxidative addition to give **106**. Alternatively, replacement of triphenylphosphine can lead to **107**, with two hydrogen atoms and a η^2 -alkene complex. If a mixture of H_2 and D_2 is used, the product contains only dideuterated and non-deuterated compounds; no mono-deuterated products are found, indicating that (unlike the case of heterogeneous catalysis) H_2 or D_2 has been added to one alkene molecule and that no exchange takes place.³³⁰ Although conversion of **107** to the products takes place in two steps,⁴⁶⁵ the addition of H_2 to the double bond is syn, although bond rotation in **109** can lead to stereochemical mixtures.

The occurrence of hydrogen exchange and double-bond migration in heterogeneous catalytic hydrogenation means that the hydrogenation does not necessarily

take place by straightforward addition of two hydrogen atoms at the site of the original double bond. Consequently, this method is not synthetically useful for adding D_2 to a double or triple bond in a regioselective or stereospecific manner. However, this objective can be achieved (with syn addition) by a homogeneous catalytic hydrogenation, which usually adds D_2 without scrambling⁴⁶⁶ or by the use of one of the diimide methods (15-12). Deuterium can also be regioselectively added by the hydroboration–reduction procedure previously mentioned.

trans-alkene.⁴⁷⁷ Samarium iodide in water and a triamine additive led to reduction of alkenes.⁴⁷⁸ Similar reduction was reported using $\text{Co}_2(\text{CO})_8$ and an excess of water in dimethoxyethane.⁴⁷⁹ Reduction of an alkyne to an alkene can be done via an organometallic, by heating the alkyne with indium metal in aqueous ethanol.⁴⁸⁰ Alkynes are reduced with palladium acetate and sodium ethoxide. In methanol the product is the alkane, whereas in THF the product is the cis-alkene.⁴⁸¹

In the above-mentioned reactions with hydrazine and hydroxylamine, the actual reducing species is diimide $\text{NH}=\text{NH}$, which is formed from N_2H_4 by the oxidizing agent and from NH_2OH by the ethyl acetate.⁴⁸² The rate of this reaction has been studied.⁴⁸³ Although both the syn and anti forms of diimide are produced, only the syn form reduces the double bond,⁴⁸⁴ at least in part by a cyclic mechanism:⁴⁸⁵

The addition is therefore stereospecifically syn⁴⁸⁶ and, like catalytic hydrogenation, generally takes place from the less-hindered side of a double bond, although not much discrimination in this respect is observed where the difference in bulk effects is small.⁴⁸⁷ Diimide reductions are most successful with symmetrical multiple bonds ($\text{C}=\text{C}$, $\text{C}\equiv\text{C}$, $\text{N}=\text{N}$) and are not useful for those inherently polar ($\text{C}\equiv\text{N}$, $\text{C}=\text{N}$, $\text{C}=\text{O}$, etc.). Diimide is not stable enough for isolation at ordinary temperatures, although it has been prepared⁴⁸⁸ as a yellow solid at -196°C . *N*-Arylsulfonylhydrazines bearing a phosphonate ester unit converted 1,1-diiodoalkenes ($\text{C}=\text{CI}_2$) to *gem*-diiodides, $(\text{CH}-\text{CHI}_2)$.⁴⁸⁹

An indirect method⁴⁹⁰ of double-bond reduction involves hydrolysis of boranes (prepared by **15-16**). Trialkylboranes can be hydrolyzed by refluxing with carboxylic

acids,⁴⁹¹ while monoalkylboranes, RBH_2 , can be hydrolyzed with base.⁴⁹² Triple bonds can be similarly reduced, to cis alkenes.⁴⁹³ Further reduction is also possible. When an alkyne was treated with decaborane and Pd/C in methanol, two equivalents of hydrogen are transferred to give the alkane.⁴⁹⁴ Hydrogenation with Ni_2B on borohydride exchange resin (BER) has also been used.⁴⁹⁵ Reduction occurs *in situ* when an alkene is treated with NaBH_4 , $\text{NiCl}_2 \cdot 6 \text{H}_2\text{O}$ with moist alumina.⁴⁹⁶ Reduction of alkenes occurs with *tert*-butylamine•borane complex in methanol with 10% Pd/C.⁴⁹⁷

Metallic hydrides, such as lithium aluminum hydride and sodium borohydride, do not in general reduce carbon–carbon double bonds, although this can be done in special cases where the double bond is polar, as in 1,1-diarylethenes⁴⁹⁸ and in enamines.⁴⁹⁹ Lithium aluminum hydride reduces cyclopropenes with a pendant alcohol in the allylic position to the corresponding cyclopropane.⁵⁰⁰

Triple bonds can also be selectively reduced to double bonds with diisobutylaluminum hydride (Dibal-H),⁵⁰¹ with activated zinc (see **12-38**),⁵⁰² with hydrogen and Bi_2B –borohydride exchange resin,⁵⁰³ or (internal triple bonds only) with alkali metals (Na, Li) in liquid ammonia or a low-molecular-weight amine.⁵⁰⁴ Terminal alkynes are not reduced by the Na-NH_3 procedure because they are converted to acetylide ions under these conditions. However, terminal triple bonds can be reduced to double bonds by the addition to the Na-NH_3 solution of $(\text{NH}_4)_2\text{SO}_4$, which liberates the free ethynyl group.⁵⁰⁵ The reaction of a terminal alkyne with

lithium naphthalenide and NiCl_2 effectively reduced the alkyne unit (i.e., $\text{PhC}\equiv\text{CH} \rightarrow \text{PhCH}_2\text{CH}_3$).⁵⁰⁶ This reagent is also effect for the reduction of simple alkenes.⁵⁰⁷ A mixture of NaBH_4 and BiCl_3 also reduced certain alkenes⁵⁰⁸ and An alkyne unit was reduced to an alkene, in the presence of a phenylthio group elsewhere in the molecule, using $\text{Cp}_2\text{Zr}(\text{H})\text{Cl}$.⁵⁰⁹

Reduction of just one double bond of an allene, to give an alkene, has been accomplished by treatment with Na-NH_3 ⁵¹⁰ or with Dibal-H,⁵¹¹ and by hydrogenation with $\text{RhCl}(\text{PPh}_3)_3$ as catalyst.⁵¹²

When double bonds are reduced by lithium in ammonia or amines, the mechanism is similar to that of the Birch reduction (**15-13**).⁵¹³ The reduction with trifluoroacetic acid and Et_3SiH has an ionic mechanism, with H^+ coming in from the acid and H^- from the silane.²⁹⁰ In accord with this mechanism, the reaction can be applied only to those alkenes, which when protonated can form a tertiary carbocation or one stabilized in some other way, for example, by a OR substitution.⁵¹⁴ It has been shown, by the detection of CIDNP, that reduction of α -methylstyrene by hydridopentacarbonylmanganese(I), $\text{HMn}(\text{CO})_5$, involves free-radical addition.⁵¹⁵

Catalytic hydrogenation of triple bonds and the reaction with Dibal-H usually give the cis-alkene (**15-11**). Most of the other methods of triple-bond reduction lead to the more thermodynamically stable trans alkene. However, this is not the case with the method involving hydrolysis of boranes or with the reductions with activated zinc, hydrazine, or $\text{NH}_2\text{OSO}_3\text{H}$, which also give the cis products.

The fact that ordinary double bonds are inert toward metallic hydrides is quite useful, since it permits reduction of, say, a carbonyl or nitro group, without disturbing a double bond in the same molecule (see Chapter 19 for a discussion of selectivity in reduction reactions). Sodium in liquid ammonia also does not reduce ordinary double bonds,⁵¹⁶ although it does reduce alkynes, allenes, conjugated dienes,⁵¹⁷ and aromatic rings (**15-13**).

Another hydrogenation method is called *transfer hydrogenation*.⁵¹⁸ In this method the hydrogen comes from another organic molecule, which is itself oxidized. A transition-metal catalyst, heterogeneous or homogeneous, is frequently employed. Dendritic catalysts have been used for asymmetric transfer hydrogenation.⁵¹⁹ A common reducing agent is cyclohexene, which, when a palladium catalyst is used, is oxidized to benzene, losing 2 mol of hydrogen.

Enantioselective reduction of certain alkenes has also been achieved by reducing with baker's yeast.⁵²⁰

15-13 Hydrogenation of Aromatic Rings

Aromatic rings can be reduced by catalytic hydrogenation,⁵²¹ but higher temperatures (100–200°C) are required than for ordinary double bonds.⁵²² although the reaction is usually carried out with heterogeneous catalysts, homogeneous catalysts have also been used; conditions are much milder with these.⁵²³ Mild conditions are also successful in hydrogenations with phase transfer catalysts.⁵²⁴ Hydrogenation in ionic liquids is known,⁵²⁵ and also hydrogenation in supercritical ethane containing water.⁵²⁶ Many functional groups, such as OH, O⁻, COOH, COOR, NH₂, do not interfere with the reaction, but some groups may be preferentially reduced. Among these are CH₂OH groups, which undergo hydrogenolysis to CH₃ (**19-54**). Phenols may be reduced to cyclohexanones, presumably through the enol. Heterocyclic compounds are often reduced. Thus furan gives THF. The

nitrogen-containing ring of quinolines is reduced by hydrogenation using iodine and an iridium catalyst.⁵²⁷ Catalytic hydrogenation of the five-membered ring in indole derivatives using a chiral rhodium catalyst gave hydroindoles with excellent enantioselectivity.⁵²⁸

With benzene rings it is usually impossible to stop the reaction after only one or two bonds have been reduced, since alkenes are more easily reduced than aromatic rings.⁵²⁹ Thus, 1 equivalent of benzene, treated with 1 equivalent of hydrogen, gives no cyclohexadiene or cyclohexene, but $\frac{1}{3}$ equivalent of cyclohexane and $\frac{2}{3}$ equivalent of recovered benzene. This is not true for all aromatic systems. With anthracene, for example, it is easy to stop after only the 9,10-bond has been reduced (see p. 59). Hydrogenation of phenol derivatives can lead to conjugated cyclohexenones.⁵³⁰ Hydrogenation of toluene in an ionic liquid using a ruthenium catalyst gave methylcyclohexane.⁵³¹

When aromatic rings are reduced by lithium (or potassium or sodium) in liquid ammonia (such reductions are known as *dissolving metal reductions*), usually in the presence of an alcohol (often ethyl, isopropyl, or *tert*-butyl alcohol), 1,4-addition of hydrogen takes place and nonconjugated cyclohexadienes are produced.⁵³² This reaction is called the *Birch reduction*.⁵³³ Heterocycles, such as pyrroles,⁵³⁴ furans,⁵³⁵ pyridines,⁵³⁶ and indolones,⁵³⁷ can be reduced using Birch reduction. Ammonia obtained commercially often has iron salts as impurities that lower the yield in the Birch reduction. Therefore it is often necessary to distill the ammonia. When substituted aromatic compounds are subjected to the Birch reduction, electron-donating groups, such as alkyl or alkoxy decrease the rate of the reaction and are generally found on the nonreduced positions of the product. For example, anisole gives 1-methoxy-1,4-cyclohexadiene, not 3-methoxy-1,4-cyclohexadiene. On the other hand, electron-withdrawing groups, such as COOH or CONH₂,

increase the reaction rate and are found on the reduced positions of the product.⁵³⁸ The regioselectivity of the reaction has been examined.⁵³⁹ The mechanism involves solvated electrons,⁵⁴⁰ which are transferred from the metal to the solvent, and hence to the ring:⁵⁴¹

The sodium becomes oxidized to Na^+ and creates a radical ion (**110**).⁵⁴² There is a great deal of evidence from ESR spectra for these species.⁵⁴³ The radical ion accepts a proton from the alcohol to give a radical, which is reduced to a carbanion by another sodium atom. Finally, **111** accepts another proton. Thus the function of the alcohol is to supply protons, since with most substrates ammonia is not acidic enough for this purpose. In the absence of the alcohol, products arising from dimerization of **110** are frequently obtained. There is evidence⁵⁴⁴ at least with some substrates, for example, biphenyl, that the radical ion corresponding to **110** is converted to the carbanion corresponding to **111** by a different pathway, in which the order of the steps is reversed: first a second electron is gained to give a dianion,⁵⁴² which then acquires a proton, producing the intermediate corresponding to **111**.

Ordinary alkenes are usually unaffected by Birch-reduction conditions, and double bonds may be present in the molecule if they are not conjugated with the ring. However, phenylated alkenes, internal alkynes (**15-12**),⁵⁴⁵ and conjugated alkenes (with $\text{C}=\text{C}$ or $\text{C}=\text{O}$) are reduced under these conditions.

Note that **111** is a resonance hybrid; that is, we can write the two additional canonical forms shown. The question therefore arises: Why does the carbanion pick up a proton at the 6 position to give the 1,4-diene? Why not at the 2 position

⁵³⁸These regioselectivities have generally been explained by molecular-orbital considerations regarding the intermediates involved. For example, see Birch, A.J.; Hinde, A.L.; Radom, L. *J. Am. Chem. Soc.* **1980**, *102*, 3370, 4074, 6430; **1981**, *103*, 284; Zimmerman, H.E.; Wang, P.A. *J. Am. Chem. Soc.* **1990**, *112*, 1280. to give the 1,3-diene?⁵⁴⁶ An answer to this question has been proposed by Hine, who has suggested that this case is an illustration of the operation of the *principle of least motion*.⁵⁴⁷ According to this principle, “those elementary reactions will be favored that involve the least change in atomic position and electronic configuration.”⁵⁴⁷ The principle can be applied to the case at hand in the following manner (simplified): The valence-bond bond orders (p. 32) for the six carbon–carbon bonds (on the assumption that each of the three forms contributes equally) are (going around the ring) $1\frac{2}{3}$, 1, 1, $1\frac{2}{3}$, $1\frac{1}{3}$, and $1\frac{1}{3}$. When the carbanion is converted to the diene, these bond orders change as follows:

It can be seen that the two bonds whose bond order is 1 are unchanged in the two products, but for the other four bonds there is a change. If the 1,4-diene is formed, the change is $\frac{1}{3} + \frac{1}{3} + \frac{1}{3} + \frac{1}{3}$, while formation of the 1,3-diene requires a change of $\frac{1}{3} + \frac{2}{3} + \frac{2}{3} + \frac{1}{3}$. Since a greater change is required to form the 1,3-diene, the principle of least motion predicts formation of the 1,4-diene. This may not be the only factor, because the ^{13}C NMR spectrum of **111** shows that the 6 position has a somewhat greater electron density than the 2 position, which presumably would make the former more attractive to a proton.⁵⁴⁸

Reduction of aromatic rings with lithium⁵⁴⁹ or calcium⁵⁵⁰ in amines (instead of ammonia: called *Benkeser reduction*) proceeds further and cyclohexenes are obtained. It is thus possible to reduce a benzene ring, by proper choice of reagent, so that one, two, or all three double bonds are reduced.⁵⁵¹ Lithium triethylborohydride (LiBEt_3H) has also been used, to reduce pyridine derivatives to piperidine derivatives.⁵⁵²

Transition metals and metal compounds can reduce aromatic rings in the proper medium. Indium metal reduces the pyridine ring in quinoline in aqueous ethanol solution⁵⁵³ as well as the $\text{C}=\text{C}$ unit in the five-membered ring of indole

15-14 Reduction Of The Double or Triple Bonds Conjugated to Carbonyls, Cyano, and so on.

In certain cases,⁵⁵⁹ metallic hydride reagents may also reduce double bonds in conjugation with C=O bonds, as well as reducing the C=O bonds, as in the conversion of cyclopentenone to cyclopentanol.⁵⁶⁰ The reagent NaBH₄ has a greater tendency than LiAlH₄ to effect this double reduction, although even with NaBH₄ the product of single reduction (of the C=O bond) is usually formed in larger amount than the doubly reduced product. Lithium aluminium hydride gives significant double reduction only in cinnamyl systems, for example, with PhCH=CHCOOH.⁵⁶¹ Lithium aluminium hydride also reduces the double bonds of allylic alcohols⁵⁶² and NaBH₄ in MeOH–THF⁵⁶³ or NaCNBH₃ on a zeolite⁵⁶⁴ reduces α,β -unsaturated nitro compounds to nitroalkanes. The C=C unit proximal to the carbonyl in dienyl amides is selectively reduced with NaBH₄/I₂.⁵⁶⁵ Mixed hydride reducing agents, such as NaBH₄–BiCl₃,⁵⁶⁶ NaBH₄–InCl₃,⁵⁶⁷ borohydride exchange resin (BER)–CuSO₄,⁵⁶⁸ and Dibal–Co(acac)₂⁵⁶⁹ have been

used. The $\text{InCl}_3\text{-NaBH}_4$ reagent was used to convert conjugated diene ketones ($\text{C}=\text{C}-\text{C}=\text{C}-\text{C}=\text{O}$) selectively to the nonconjugated alkenyl ketone ($\text{C}=\text{C}-\text{CH}_2\text{CH}_2-\text{C}=\text{O}$).⁵⁷⁰

Note that both LiAlH_4 and NaBH_4 , as well as NaH , reduce ordinary alkenes and alkynes when complexed with transition-metal salts, such as FeCl_2 or CoBr_2 .⁵⁷¹

Reduction of only the $\text{C}=\text{C}$ bond of conjugated $\text{C}=\text{C}-\text{C}=\text{O}$ and $\text{C}=\text{C}-\text{C}\equiv\text{N}$ systems⁵⁷² has been achieved by many reducing agents,⁵⁷³ a few of which are H_2 and a Rh catalyst,⁵⁷⁴ a Ru catalyst,⁵⁷⁵ a Pd catalyst,⁵⁷⁶ or an Ir catalyst,⁵⁷⁷ and Raney nickel alone.⁵⁷⁸ Reagents such as SmI_2 ,⁵⁷⁹ and catecholborane⁵⁸⁰ are effective. Conjugated ketones react with 2 equivalents of Cp_2TiCl in THF/MeOH to give the corresponding saturated ketone.⁵⁸¹ Indium metal in aqueous ethanol with ammonium chloride converts alkylidene dimalononitriles to the saturated dinitrile.⁵⁸² Zinc and acetic acid has been used for the conjugate reduction of dihydropyridin-4-ones.⁵⁸³ Formic acid with a palladium catalysts reduced conjugated carboxylic acids.⁵⁸⁴

Silanes can be effective for the reduction of the $\text{C}=\text{C}$ unit in conjugated systems in the presence of copper species.⁵⁸⁵ PhSiH_3 and a nickel catalyst,⁵⁸⁶ CuCl ,⁵⁸⁷ or a manganese catalyst.⁵⁸⁸ In addition, PhR_2SiH with a copper catalyst,⁵⁸⁹ and

been used for conjugated acids.⁶¹³ Asymmetric hydrogenation of conjugated carboxylic acids in an ionic liquid is known using a chiral ruthenium complex⁶¹⁴ Enamino esters have been hydrogenated with high enantioselectivity using chiral rhodium catalysts.⁶¹⁵

See **19-36** for methods of reducing C=O bonds in the presence of conjugated C=C bonds.

The C=C unit of conjugated aldehydes has been reduced using AlMe₃ with a catalytic amount of CuBr⁶¹⁶ and with ammonium formate/Pd–C.⁶¹⁷ Polymer-supported formate has been used for the 1,4-reduction of conjugated ketones⁶¹⁸ and conjugated acids using a rhodium catalyst and microwave irradiation.⁶¹⁹ Selective reduction of the C=C unit in conjugated ketones was accomplished with Na₂S₂O₄ in aqueous dioxane, and nonconjugated alkenes were not reduced.⁶²⁰ Isopropanol and an iridium catalyst gives conjugate reduction of conjugated ketones.⁶²¹ Conjugate hydrostannation by an iodotin hydride ate complex, followed by hydrolysis converts unsaturated esters to saturated esters.⁶²² The reaction of conjugated ketones with aluminum chlorides, followed by treatment with water generates the saturated ketone.⁶²³

Baker's yeast reduces conjugated nitro compounds to nitroalkanes⁶²⁴ and also the C=C unit of conjugated ketones.⁶²⁵ Other enzymatic reductions are possible. A reductase from *Nicotiana tabacum* reduced a conjugated ketone to the saturated ketone, with excellent enantioselectivity.⁶²⁶ Enzyme YNAR-I and NADP-H reduces conjugated nitro compounds to nitroalkanes.⁶²⁷

Cyclopropanes can be cleaved by catalytic hydrogenolysis.⁶²⁸ Among the catalysts used have been Ni, Pd, Rh,⁶²⁹ and Pt. The reaction can often be run under mild conditions.⁶³⁰ Certain cyclopropane rings, especially cyclopropyl ketones and aryl-substituted cyclopropanes,⁶³¹ can be reductively cleaved by an alkali metal (generally Na or Li) in liquid ammonia.⁶³² Similar reduction has been accomplished photochemically in the presence of LiClO₄.⁶³³ This reaction is an excellent way to introduce a *gem*-dimethyl unit into a molecule. Hydrogenation of the cyclopropane ring in **114**, for example, gave the *gem*-dimethyl unit in **115** using PtO₂ (Adam's catalyst).⁶³⁴

'ate' complexes with THF, Me_2S ,⁶³⁸ phosphines, or tertiary amines. The alkenes can be treated with a solution of one of these complexes (THF- BH_3 reacts at 0°C and is the most convenient to use; $\text{R}_3\text{N}-\text{BH}_3$ generally require temperatures of $\sim 100^\circ\text{C}$; however, the latter can be prepared as air-stable liquids or solids, while the former can only be used as relatively dilute solutions in THF and are decomposed by moisture in air) or with a mixture of NaBH_4 and BF_3 etherate, which generates borane *in situ*.⁶³⁹ With relatively unhindered alkenes, the process cannot be stopped with the addition of one molecule of BH_3 because the resulting RBH_2 adds to another molecule of alkene to give R_2BH , which in turn adds to a third alkene molecule, so that the isolated product is a trialkylborane R_3B . The reaction can be performed on alkenes with one to four substituents, including cyclic alkenes, but when the alkene is moderately hindered, the product is the dialkylborane R_2BH or even the monoalkylborane RBH_2 .⁶⁴⁰ For example, **116** (*disiamylborane*) and **117** (*thexylborane*)⁶⁴¹ have been prepared in this manner. Monoalkylboranes RBH_2 (which can be prepared from hindered alkenes, as above) and dialkylboranes R_2BH also add to alkenes, to give the mixed trialkylboranes $\text{RR}'_2\text{B}$ and $\text{R}_2\text{R}'\text{B}$, respectively. Surprisingly, when methylborane MeBH_2 ,⁶⁴² which is not a bulky molecule, adds to alkenes in the solvent THF, the reaction can be stopped with one addition to give the dialkylboranes RMeBH .⁶⁴³ Reaction of this with a second alkene produces the trialkylborane $\text{RR}'\text{MeB}$.⁶⁴⁴ Other monoalkylboranes, *i*-Pr BH_2 , *n*-Bu BH_2 , *s*-Bu BH_2 , and *t*-Bu BH_2 , behave similarly with internal alkenes, but not with alkenes of the type $\text{RCH}=\text{CH}_2$.⁶⁴⁵

In all cases, the boron goes to the side of the double bond that has more hydrogens, whether the substituents are aryl or alkyl.⁶⁴⁶ This actually follows Markovnikov's rule, since boron is more positive than hydrogen. However, the regioselectivity is caused mostly by steric factors, although electronic factors also play a part. Studies of the effect of ring substituents on rates and on the direction of attack in hydroboration of substituted styrenes showed that the reaction with boron and the alkene has electrophilic character.⁶⁴⁷ When both sides of the double bond are monosubstituted or both disubstituted, about equal amounts of each isomer are obtained. However, it is possible in such cases to make the addition regioselective by the use of a large borane molecule. For example, treatment of *i*PrCH=CHMe with borane gave 57% of product with boron on the methyl-bearing carbon and 43% of the other, while treatment with **116** gave 95% **118** and only 5% of the other isomer.⁶⁴⁸

Another reagent with high regioselectivity is 9-borabicyclo[3.3.1]nonane (9-BBN), which is prepared by hydroboration of 1,5-cyclooctadiene,⁶⁴⁹ and has the advantage that it is stable in air. Borane is quite unselective and attacks all sorts of double bonds. Disiamylborane, 9-BBN, and similar molecules are far more selective and preferentially attack less-hindered bonds, so it is often possible to hydroborate one double bond in a molecule and leave others unaffected or to hydroborate one alkene in the presence of a less reactive alkene.⁶⁵⁰ For example, 1-pentene can be removed from a mixture of 1- and 2-pentenes, and a *cis* alkene can be selectively hydroborated in a mixture of the *cis* and *trans* isomers.

⁶⁴⁶For a thorough discussion of the regioselectivity with various types of substrate and hydroborating agents, see Cragg, G.M.L. *Organoboranes in Organic Synthesis* Marcel Dekker, NY, **1973**, pp.63–84, 137–197. For most substrates, the addition in hydroboration is stereospecific and syn, with attack taking place from the less-hindered side.⁶⁵¹ Note that organoboranes can be analyzed using ¹¹B nmr.⁶⁵² The mechanism⁶⁵³ may be a cyclic four-center one:⁶⁵⁴

When the substrate is an allylic alcohol or amine, the addition is generally anti,⁶⁵⁵ although the stereoselectivity can be changed to syn by the use of catecholborane and the rhodium complexes mentioned above.⁶⁵⁶ Because the mechanism is different, use of this procedure can result in a change in regioselectivity as well, for example, styrene $\text{PhCH}=\text{CH}_2$ gave $\text{PhCH}(\text{OH})\text{CH}_3$.⁶⁵⁷

Monochloroborane⁶⁵⁸ BH_2Cl coordinated with dimethyl sulfide shows greater regioselectivity than BH_3 for terminal alkenes or those of the form $\text{R}_2\text{C}=\text{CHR}$, and the hydroboration product is a dialkylchloroborane R_2BCl .⁶⁵⁹ For example, 1-hexene gave 94% of the anti-Markovnikov product (the boron is on the less substituted carbon) with $\text{BH}_3\text{-THF}$, but 99.2% with $\text{BH}_2\text{Cl-SMe}_2$. Treatment of alkenes with dichloroborane dimethyl sulfide $\text{BHCl}_2\text{-SMe}_2$ in the presence of BF_3 ⁶⁶⁰ or with BCl_3 and Me_3SiH ⁶⁶¹ gives alkyl dichloroboranes RBCl_2 . Extensions of this basic approach are possible with dihalo alkylboranes. The reaction of an alkene with allyl dibromoborane, incorporated an allyl group and the boron on adjacent carbons.⁶⁶²

An important use of the hydroboration reaction is oxidation of an organoborane to alcohols with hydrogen peroxide and NaOH (**12-27**). Organoboranes have been oxidized with Oxone[®]⁶⁶³ and methanol/triethylamine/molecular oxygen.⁶⁶⁴ The synthetic result is an indirect way of adding H₂O across a double bond in an anti-Markovnikov manner. However, boranes undergo many other reactions as well. Among other things, they react with α -halo carbonyl compounds to give alkylated products (**10-73**), with α,β -unsaturated carbonyl compounds to give Michael-type addition of R and H (**15-27**), with CO to give alcohols and ketones (**18-23–18-24**); they can be reduced with carboxylic acids, providing an indirect method for reduction of double bonds (**15-11**), or they can be oxidized with chromic acid or pyridinium chlorochromate to give ketones⁶⁶⁵ or aldehydes (from terminal alkenes),⁶⁶⁶ dimerized with silver nitrate and NaOH (**14-26**), isomerized (**18-11**), or converted to amines (**12-32**), halides (**12-31**), or carboxylic acids.⁶⁶⁷ They are thus useful intermediates for the preparation of a wide variety of compounds. Intramolecular hydroboration reaction are possible.⁶⁶⁸

Such functional groups as OR, OH, NH₂, SMe, halogen, and COOR may be present in the molecule,⁶⁶⁹ but not groups that are reducible by borane. Hydroboration of enamines with 9-BBN provides an indirect method for reducing an aldehyde or ketone to an alkene, e.g.⁶⁷⁰

Enamines can also be converted to amino alcohols via hydroboration.⁶⁷¹ Allen-boranes react with aldehydes to give alkyne–alcohols.⁶⁷²

Use of the reagent diisopinocampheylborane **119** (prepared by treating optically active α -pinene with BH₃) results in enantioselective hydroboration–oxidation.⁶⁷³ Since both (+) and (–) α -pinene are readily available, both enantiomers

can be prepared. Alcohols with moderate-to-excellent enantioselectivities have been

obtained in this way.⁶⁷⁴ However, **119** does not give good results with even moderately hindered alkenes; a better reagent for these compounds is isopinocampheylborane⁶⁷⁵ although optical yields are lower. Limonylborane,⁶⁷⁶ 2- and 4-dicaranylboranes,⁶⁷⁷ a myrtanylborane,⁶⁷⁸ and dilongifolyborane⁶⁷⁹ have also been used. Other new asymmetric boranes have also been developed. The chiral cyclic boranes *trans*-2,15-dimethylborolanes (**51** and **52**) also add enantioselectively to alkenes (except

alkenes of the form $\text{RR}'\text{C}=\text{CH}_2$) to give boranes of high optical purity.⁶⁸⁰ When chiral boranes are added to trisubstituted alkenes of the form $\text{RR}'\text{C}=\text{CHR}''$, two new chiral centers are created, and, with **120** or **121**, only one of the four possible diastereomers is predominantly produced, in yields $> 90\%$.⁶⁸⁰ This has been called *double-asymmetric synthesis*.⁶⁸¹ An alternative asymmetric synthesis of alcohols involves the reaction of catechol borane with an alkene in the presence

⁶⁸¹For another enantioselective hydroboration method, see p. 1082.

of a chiral rhodium catalyst, giving the alcohol enantioselectivity after the usual oxidation.⁶⁸²

The double bonds in a conjugated diene are hydroborated separately, that is, there is no 1,4-addition. However, it is not easy to hydroborate just one of a conjugated system, since conjugated double bonds are less reactive than isolated ones. Thexylborane⁶⁴¹ (**117**) is particularly useful for achieving the cyclic hydroboration of dienes, conjugated or nonconjugated, as in the formation of **122**.⁶⁸³

Rings of five, six, or seven members can be formed in this way. Similar cyclization can also be accomplished with other monoalkylboranes and, in some instances, with BH_3 itself.⁶⁸⁴ One example is the formation of 9-BBN, shown above. Another is conversion of 1,5,9-cyclododecatriene to perhydro-9*b*-boraphenalene, **123**.⁶⁸⁵ If a diene is treated with a diaminoborane and a samarium catalyst, oxidation leads to a carbocyclic ring with a pendant hydroxymethyl group.⁶⁸⁶

Triple bonds⁶⁸⁷ can be monohydroborated to give vinylic boranes, which can be reduced with carboxylic acids to cis-alkenes or oxidized and hydrolyzed to aldehydes or ketones. Terminal alkynes give aldehydes by this method, in contrast to the mercuric or acid-catalyzed addition of water discussed at **15-4**. However, terminal alkynes give vinylic boranes⁶⁸⁸ (and hence aldehydes) only when treated with a hindered borane, such as **116**, **117**, or catecholborane (p. 820),⁶⁸⁹ or with $\text{BHB}r_2\text{-SMe}_2$.⁶⁹⁰ The reaction between terminal alkynes and BH_3 produces

1,1-dibora compounds, which can be oxidized either to primary alcohols (with NaOH-H₂O₂) or to carboxylic acids (with *m*-chloroperoxybenzoic acid).⁶⁹¹ Double bonds can be hydroborated in the presence of triple bonds if the reagent is 9-BBN.⁶⁹² On the other hand, dimesitylborane selectively hydroborates triple bonds in the presence of double bonds.⁶⁹³ Furthermore, it is often possible to hydroborate selectively one particular double bond of a nonconjugated diene.⁶⁹⁴ A triple bond can be hydroborated in the presence of a ketone, and treatment with acetic acid reduces the C≡C unit to a *cis*-alkene (see **15-12**).⁶⁹⁵ When the reagent is catecholborane, hydroboration is catalyzed by rhodium complexes,⁶⁹⁶ such as Wilkinson's catalyst,⁶⁹⁷ by SmI₂,⁶⁹⁸ or lanthanide reagents.⁶⁹⁹ Enantioselective hydroboration-oxidation has been achieved by the use of optically active rhodium complexes.⁷⁰⁰

A chain extension variation involved the reaction of styrene with catecholborane and then Me₃SiCHN₂.⁷⁰¹ Subsequent oxidation with NaOH/H₂O₂ and the reaction with Bu₄NF gave 3-phenyl-1-propanol.

An unusual extension of hydroboration involves remote C-H activation. Aryl alkenes are treated with borane and then oxidized in the usual manner. The product is a phenol and a hydroxymethyl group (Ph-C=C-CH₃ → *o*-Ph-CH-CH-CH₂OH).⁷⁰²

Ar_3SnH) add to double bonds to give organometallic compounds.⁷⁰³ The hydroboration reaction (15-16) is the most important example, but other important metals in this reaction are aluminum,⁷⁰⁴ tin,⁷⁰⁵ and zirconium⁷⁰⁶ [a Group 4 (IV B) metal]. Some of these reactions are uncatalyzed, but in other cases various types of catalyst have been used.⁷⁰⁷ Hydrozirconation is most commonly carried out with Cp_2ZrHCl (Cp = cyclopentadienyl),⁷⁰⁸ known as *Schwartz's reagent*. The mechanism with Group 13 (III A) hydrides seems to be electrophilic (or four-centered pericyclic with some electrophilic characteristics) while with Group 14 (IV A) hydrides a mechanism involving free radicals seems more likely. Dialkylmagnesium reagents have been obtained by adding MgH_2 to double bonds.⁷⁰⁹ With Grignard reagents such as RMgX , the Grignard reagent can be added to an alkene $\text{R}'\text{CH}=\text{CH}_2$ to give $\text{R}'\text{CH}_2\text{CH}_2\text{MgX}$, with TiCl_4 as a catalyst.⁷¹⁰ With some reagents triple bonds⁷¹¹ can add 1 or 2 equivalents, to give 124 or 125.⁷¹²

G. Carbon or Silicon on the Other Side

15-18 Addition of Alkanes

Hydro-alkyl-addition

There are two important ways of adding alkanes to alkenes: the thermal and the acid-catalysis method.⁷¹³ Both give chiefly mixtures, and neither is useful for the preparation of relatively pure compounds in reasonable yields. However, both are useful industrially. In the thermal method the reactants are heated to high temperatures (~500°C) at high pressures (150–300 atm) without a catalyst. As an example, propane and ethylene gave 55.5% isopentane, 7.3% hexanes, 10.1% heptanes, and 7.4% alkenes.⁷¹⁴ The mechanism is undoubtedly of a free-radical type and can be illustrated by one possible sequence in the reaction between propane and ethylene:

There is kinetic evidence that the initiation takes place primarily by steps like 1, which are called *symproportionation* steps⁷¹⁵ (the opposite of disproportionation, p. 280).

In the acid-catalysis method, a proton or Lewis acid is used as the catalyst and the reaction is carried out at temperatures between –30 and 100°C. This is a Friedel–Crafts process with a carbocation mechanism⁷¹⁶ (illustrated for a proton

Conjugated dienes give 1,4-addition.⁷²⁴ This reaction has also been performed with salts of carboxylic acids in what amounts to a method of alkylation of carboxylic acids⁷²⁵ (see also, **10-59**).

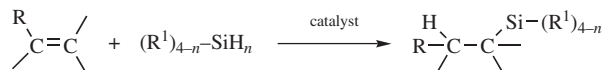

There are transition-metal catalyzed addition reaction of alkyl units to alkenes,⁷²⁶ often proceeding with metal hydride elimination to form an alkene. An intramolecular cyclization reaction of an *N*-pyrrolidino amide alkene was reported using an iridium catalyst for addition of the carbon α to nitrogen to the alkene unit.⁷²⁷

OS I, 229; IV, 665; VII, 479.

15-19 Addition of Silanes

Silyl-hydro-addition

Although silanes bearing at least one Si-H unit do not generally react with alkenes or alkynes, in the presence of certain catalyst addition occurs to give the corresponding alkyl or vinyl silane. The reaction of an alkene with an yttrium,⁷²⁸ ruthenium,⁷²⁹ rhodium,⁷³⁰ palladium,⁷³¹ lanthanum,⁷³² platinum⁷³³, or samarium⁷³⁴ catalyst addition occurs with high anti-Markovnikov selectivity. Silanes add to dienes with a palladium catalyst, and asymmetric induction is achieved by using a binaphthyl additive.⁷³⁵ Alkenes react with Li-(0) and *t*-Bu₂SiCl₂ to give a three-membered ring silane.⁷³⁶ In the presence of BEt₃, silanes add to alkynes to give the corresponding vinyl silane⁷³⁷ or to alkenes to give the alkylsilane, with

⁷³⁷Miura, K.; Oshima, K.; Utimoto, K. *Bull. Chem. Soc. Jpn.* **1993**, *66*, 2356.

anti-Markovnikov selectivity.⁷³⁸ Similar selectivity was observed when a silylated zinc reagent was added to a terminal alkyne.⁷³⁹ Silanes add to alkynes to give a vinyl silane using Cp_2TiCl_2 -*n*-butyllithium.⁷⁴⁰ Siloxanes such as $(\text{RO})_3\text{SiH}$ add to alkynes with a ruthenium catalyst to give the corresponding vinyl silane.⁷⁴¹ The reaction of Cl_2MeSiH and terminal alkynes, in ethanol–triethylamine with a ruthenium catalyst, to give primarily the Markovnikov vinyl silane.⁷⁴² However, Et_3SiH adds to terminal alkynes with a rhodium⁷⁴³ or a platinum⁷⁴⁴ catalyst to give the anti-Markovnikov vinyl silane. Using 0.5 equivalent of HfClO_4 with alkynes bearing a dimethylphenylsilyl unit gave a cyclic vinyl silane with transfer of the phenyl group to carbon (see **128**).⁷⁴⁵ Dienes react with zirconium compounds and silanes to produce cyclic compounds in which the silyl group has also added to one $\text{C}=\text{C}$ unit.⁷⁴⁶ With an yttrium catalyst, PhSiH_3 reacts with nonconjugated dienes to give cyclic alkenes with a pendant $\text{CH}_2\text{SiH}_2\text{Ph}$ group.⁷⁴⁷ Rhodium compounds allow silanes to add to enamides to give the α -silylamide.⁷⁴⁸ Allylsilanes add to certain allylic alcohols in the presence of Me_3SiOTf , via a $\text{S}_{\text{N}}2'$ -like reaction, to give dienes.⁷⁴⁹ Note that silanes open cyclopropane rings in the presence of 20% AlCl_3 to give the alkylsilane.⁷⁵⁰ Formation of silanes via reaction with alkenes can be followed by reaction with fluoride ion and then oxidation to give an alcohol⁷⁵¹ (see **10-16**).

Silanes also add to alkenes under radical conditions (using AIBN) with high anti-Markovnikov selectivity.⁷⁵² An alternative route to alkylsilanes reacted an alkene with lithium metal in the presence of 3 equivalents of chlorotrimethylsilane, giving bis-1,2-trimethylsilyl compounds after treatment with water.⁷⁵³ Silanes also

add to alkenes to form anti-Markovnikov alkylsilane ($R_3Si-C-C-R'$) in the presence of a hyponitrite.⁷⁵⁴

Vinyl silanes add to conjugated carbonyl compounds in the presence of a ruthenium catalyst,⁷⁵⁵ or to acrylonitriles with a cobalt catalyst.⁷⁵⁶ Silyl phosphines react with conjugated ynone directly to give an enone with an α -trimethylsilyl and a β -phosphine group.⁷⁵⁷ Siloxanes of the type $(RO)_3SiH$ add to the α -carbon of enamines in the presence of a dirhodium catalyst.⁷⁵⁸ The uncatalyzed reaction of trimethylsilyl cyanide and ynamines, however, gave an enamine with a β -trimethylsilyl and an α -cyano group.⁷⁵⁹

15-20 Addition of Alkenes and/or Alkynes to Alkenes and/or Alkynes

Hydro-alkenyl-addition

With certain substrates, alkenes can be dimerized by acid catalysts, so that the product is a dimer that contains one double bond.⁷⁶⁰ A combination of zinc and a $CoCl_2$ catalyst accomplished the same type of coupling.⁷⁶¹ One alkene adds to another in the presence of a nickel catalyst.⁷⁶² Coupling conjugated alkenes with vinyl esters to give a functionalized conjugated diene is known, using a complex palladium–vanadium catalyst in an oxygen atmosphere.⁷⁶³ This reaction is more often carried out internally, as in the formation of cyclohexene **129**. A palladium catalyzed cyclization is known, in which dienes are converted to cyclopentene derivatives such as **130**.⁷⁶⁴ Ring-forming reactions with heterocyclic compounds such as indoles are known using $PtCl_2$.⁷⁶⁵ A ruthenium catalyzed version of this reaction gave the five-membered ring with an exocyclic double bond.⁷⁶⁶ Carbocyclization of an alkene unit to another alkene unit was reported

using an yttrium catalyst,⁷⁶⁷ or a titanium catalyst.⁷⁶⁸ In some cases, internal coupling of two alkenes can form larger rings.⁷⁶⁹ Variations include treatment of similar dienes with $\text{HSiMe}_2\text{OSiMe}_3$ and KF -acetic acid to give a cyclopentane with a pendant trimethylsilylmethyl group trans to a methyl.⁷⁷⁰ Exo-dig carbocyclization was reported using HfCl_4 ⁷⁷¹ palladium,⁷⁷² or titanium,⁷⁷³ catalysts. Alkynes also add to alkenes to form rings in the presence of a palladium,⁷⁷⁴ rhodium,⁷⁷⁵ ruthenium,⁷⁷⁶ iridium,⁷⁷⁷ or a zirconium catalyst.⁷⁷⁸ Alkene allene substrates were cyclized to form cyclic products with an exocyclic double bond using a palladium catalyst.⁷⁷⁹ An interesting variation adds a silyl enol ether to an alkyne using GaCl_3 to give an unconjugated ketone ($\text{O}=\text{C}-\text{C}-\text{C}=\text{C}$).⁷⁸⁰ Alkenes and alkynes can also add to each other to give cyclic products in other ways (see 15-63 and 15-65).

Processes of this kind are important in the biosynthesis of steroids and tetra- and pentacyclic terpenes. For example, squalene 2,3-oxide is converted by enzymatic

catalysis to dammaradienol.

The squalene \rightarrow lanosterol biosynthesis (which is a key step in the biosynthesis of cholesterol) is similar. The idea that the biosynthesis of such compounds involves this type of multiple ring closing was proposed in 1955 and is known as the *Stork–Eschenmoser hypothesis*.⁷⁸¹ Such reactions can also be carried out in the laboratory, without enzymes.⁷⁸² By putting cation-stabilizing groups at positions at which positive charges develop, Johnson and co-workers have been able to close as many as four rings stereoselectively and in high yield, in one operation.⁷⁸³ An example is formation of **131**,⁷⁸⁴ also known as the *Johnson polyene cyclization*.⁷⁸⁵

Lewis acids can be used to initiate this cyclization,⁷⁸⁶ including EtAlCl_2 used for the coupling of an alkyne and an alkene.⁷⁸⁷ Cyclization to a tricyclic systems that included formation of a dihydropyran ring was reported using mercuric

bis(trifluorosulfonate) as an initiator.⁷⁸⁸ A radical cyclization approach (15-30) to polyene cyclization using a seleno-ester anchor gave a tetracyclic system.⁷⁸⁹

The addition of alkenes to alkenes⁷⁹⁰ can also be accomplished by bases.⁷⁹¹ Coupling reactions can occur using catalyst systems⁷⁹² consisting of nickel complexes and alkylaluminum compounds (known as *Ziegler catalysts*),⁷⁹³ rhodium catalysts,⁷⁹⁴ and other transition-metal catalysts, including iron.⁷⁹⁵ The 1,4-addition of alkenes to conjugated dienes to give nonconjugated dienes⁷⁹⁶ occurs with various transition-metal catalysts.

and the dimerization of 1,3-butadienes to octatrienes.⁷⁹⁷ Ethylene adds to alkenes to form a new alkene in the presence of a nickel catalyst⁷⁹⁸ or a zirconium catalyst,⁷⁹⁹ to alkynes in the presence of a ruthenium catalyst⁸⁰⁰ to form a diene, and allenes add to alkynes to give a diene with a titanium catalyst.⁸⁰¹

In the presence of cuprous chloride and ammonium chloride, acetylene adds to another molecule of itself to give vinylacetylene.

This type of alkyne dimerization is also catalyzed by nickel,⁸⁰² palladium,⁸⁰³ lutetium,⁸⁰⁴ and ruthenium catalysts.⁸⁰⁵ Similar products are obtained by the cross-coupling of terminal alkynes with allene, using a combination of palladium and CuI catalysts.⁸⁰⁶ The reaction has been carried out internally to convert diynes to large-ring cycloalkynes with an exocyclic double bond.⁸⁰⁷ Dienes have also been cyclized to form cyclic enynes (an endocyclic double bond) using a diruthenium catalyst with ammonium tetrafluoroborate in methanol.⁸⁰⁸ Enynes are similarly cyclized to cyclic alkenes with an endocyclic C=C unit, analogous to formation of **200** above, using a dicobalt catalyst.⁸⁰⁹ A molecule containing two distal conjugated diene units was cyclized to give a bicyclic molecule with an exocyclic double bond using a palladium catalyst.⁸¹⁰ A nickel catalyst converted a similar system to a saturated five-membered ring containing an allylic group and a vinyl group.⁸¹¹

In another type of alkyne dimerization is the reductive coupling in which two molecules of alkyne, the same or different, give a 1,3-diene.⁸¹²

In this method, one alkyne is treated with Schwartz's reagent (see **15-17**) to produce a vinylic zirconium intermediate. Addition of MeLi or MeMgBr, followed by the second alkyne, gives another intermediate, which, when treated with aqueous acid, gives the diene in moderate-to-good yields. The stereoisomer shown is the one formed in usually close to 100% purity. If the second intermediate is treated with I₂ instead of aqueous acid, the 1,4-diiodo-1,3-diene is obtained instead, in comparable yield and isomeric purity. The reaction of alkynes with two equivalents of trimethylsilyldiazomethane and a ruthenium catalyst gave a conjugated diene with trimethylsilyl groups at C-1 and C-4.⁸¹³ Alkynes can also be coupled to allylic silyl ethers with a ruthenium catalysts to give dienes.⁸¹⁴ Other alkyne-allylic coupling reactions are known to give dienes.⁸¹⁵

This reaction can also be done intramolecularly, as in the cyclization of diyne **132** to (*E,E*)-exocyclic dienes **133** by treatment with a zirconium,⁸¹⁶ rhodium,⁸¹⁷ or platinum complex.⁸¹⁸ A similar reaction was reported using a titanium catalyst from a diyne amide.⁸¹⁹

Rings of four, five, and six members were obtained in high yield; seven-membered rings in lower yield. When the reaction is applied to enynes, compounds similar to **133** are formed using various catalysts, but with only one double bond⁸²⁰ Internal coupling of alkene–allenes and a rhodium catalyst give similar products bearing a pendant vinyl group.⁸²¹ With a $PtCl_2$ catalyst, ring closure leads to a diene in some cases.⁸²² Larger rings can be formed from the appropriate enyne, including forming cyclohexadiene compounds.⁸²³ Spirocyclic compounds can be prepared from enynes in this manner using formic acid and a palladium catalyst.⁸²⁴ Enynes can also be converted to bicyclo[3.1.0]hexenes⁸²⁵ or nonconjugated cyclohexadienes⁸²⁶ using a gold catalyst. Internal coupling of an alkyne and a vinylidene cyclopropane unit with a palladium catalyst leads to a cyclopentene derivative with an exocyclic double bond.⁸²⁷ Enynes having a conjugated alkene unit also undergo this reaction

in the presence of ZnBr_2 .⁸²⁸ Using mercury (II) triflate in water, cyclization leads to five-membered rings having an exocyclic double bond, and a pendant alcohol group.⁸²⁹ Enynes give cyclic compounds with an endocyclic double bond conjugated to another alkene unit (a conjugated diene) when treated with GaCl_3 ⁸³⁰ or a platinum catalyst in an ionic liquid.⁸³¹ Allene–alkenes give a similar product with a palladium catalyst⁸³² or a ruthenium catalyst,⁸³³ as do alkyne–allenes with a dirhodium catalyst.⁸³⁴ Ethers having an enyne unit (propargylic and allylic) give dihydrofurans upon treatment with $\text{Co}_2(\text{CO})_8$.⁸³⁵ Amines and sulfonamides bearing two propargyl groups cyclize with a ruthenium catalyst to give the corresponding dihydropyrrrole.⁸³⁶

There are many useful variations. Internal coupling of an alkyne with a vinyl halide, using triethylsilane and a palladium catalyst, gave the saturated cyclic compound with two adjacent exocyclic double bonds (a 2,3-disubstituted diene).⁸³⁷ Alkynes can be added to propargyl acetates using palladium catalyst to give an alkyne allene.⁸³⁸ Two-Substituted malonate esters having a distal alkyne unit generated vinylidene cycloalkanes when treated with a catalytic amount of *n*-butyllithium.⁸³⁹ Intramolecular coupling of alkenes and allylic sulfides using *tert*-butoxide/*n*-butyllithium, and then LiBr leads to a bicyclic compound containing a fused cyclopropane ring.⁸⁴⁰ The reaction of an alkyne with a vinyl iodide and silver carbonate, with a palladium catalyst, gave a fulvene.⁸⁴¹ The reaction of a terminal alkyne and a vinyl cyclopropane, with a dirhodium catalyst, gives a cycloheptadiene.⁸⁴² Alkyne–alkenes were formed by coupling terminal alkynes and allenes in the presence of a palladium catalyst.⁸⁴³ An alkyne was coupled internally to an allene using a palladium catalyst, with an exocyclic methylene

group trapped and a vinyltin derivative.⁸⁴⁴ A similar process occurred with a rhodium catalyst, $\text{RhCl}(\text{PPh}_3)_3$, to incorporate a vinyl chloride.⁸⁴⁵ Allene-allylic halide systems reacted with phenylboronic acid and a palladium catalyst to give cyclopentane rings with two pendant vinyl groups, one of which contained a phenyl group.⁸⁴⁶

In another reductive coupling, substituted alkenes ($\text{CH}_2=\text{CH}-\text{Y}$; $\text{Y}=\text{R}$, COOMe , OAc , CN , etc.) can be dimerized to substituted alkanes $\text{CH}_3\text{CHY}-\text{CHYCH}_3$ by photolysis in an H_2 atmosphere, using Hg as a photosensitizer.⁸⁴⁷ Still another procedure involves palladium-catalyzed addition of vinylic halides to triple bonds to give 1,3-dienes.⁸⁴⁸

An important cyclization procedure involves acid-catalyzed addition of diene-ketones, such as **134**, where one conjugated alkene adds to the other conjugated alkene to form cyclopentenones (**135**). This is called the *Nazarov cyclization*.⁸⁴⁹ Structural variations are possible that prepare a variety of cyclopentenones. When one of the $\text{C}=\text{C}$ units is a vinyl ether, a cyclopentenone is formed with an oxygen attached to the alkenyl carbon.⁸⁵⁰ Substituents on the $\text{C}=\text{C}$ units, including $-\text{CO}_2\text{Et}$, lead to cyclopentenones that bear those substituents. The use of such a substrate with AgSbF_6 , CuBr_2 and a chiral ligand gave the cyclopentenone with modest enantioselectivity.⁸⁵¹ Cyclization can also give the nonconjugated five-membered ring.⁸⁵² A reductive Nazarov cyclization was reported using $\text{BF}_3 \cdot \text{OEt}_2$ and Et_3SiH , giving a cyclopentanone rather than a cyclopentenone.⁸⁵³ A palladium catalyzed reaction that is related to the Nazarov cyclization converts terminal

15-21 Addition of Organometallics to Double and Triple Bonds Not Conjugated to Carbonyls

Hydro-alkyl-addition

Neither Grignard reagents nor lithium dialkylcopper reagents generally add to ordinary C=C double bonds.⁸⁵⁷ An exception is the reaction of $(\text{PhMe}_2\text{Si})_2\text{Cu}(\text{CN})\text{Li}$ to 8-oxabicyclo[3.2.1]oct-2-ene derivatives.⁸⁵⁸ Grignard reagents usually add only to double bonds susceptible to nucleophilic attack, (e.g., fluoroalkenes and tetracyanoethylene).⁸⁵⁹ However, active Grignard reagents (benzylic, allylic) also add to the double bonds of allylic amines,⁸⁶⁰ and of allylic and homoallylic alcohols,⁸⁶¹ as well as to the triple bonds of propargyl alcohols and certain other alkynols.⁸⁶² Grignard reagents also add to alkynes in the presence of MnCl_2 at 100°C ⁸⁶³ and to alkenes in the presence of zirconium⁸⁶⁴ or nickel⁸⁶⁵ catalysts. It is likely that cyclic intermediates are involved in these cases, in which the magnesium coordinates with the heteroatom. Allylic, benzylic, and tertiary alkyl Grignard reagents also add to 1-alkenes and strained internal alkenes (e.g., norbornene), if the reaction is carried

out in a hydrocarbon solvent, such as pentane rather than ether, or in the alkene itself as solvent, heated, under pressure if necessary, to 60–130°C.⁸⁶⁶ Yields are variable. *Intramolecular* addition of RMgX to completely unactivated double and triple bonds has been demonstrated.⁸⁶⁷ The reaction of tosylates bearing a remote alkene unit and a Grignard reagent leads to cyclization when a zirconium catalyst is used.⁸⁶⁸ The intramolecular addition of a CH_2Br unit to the $\text{C}=\text{C}$ unit of an allylic ether was accomplished using PhMgBr and a cobalt catalyst, give a functionalized tetrahydrofuran and incorporation of the phenyl group on the $\text{C}=\text{C}$ unit as well.⁸⁶⁹ Grignard reagents add to the $\text{C}=\text{C}$ unit of $(\text{MeO})_2\text{CRCH}=\text{CH}-\text{R}$ moieties to give a 3-alkyl substituted ketone with good enantioselectivity using a nickel catalyst and a chiral additive.⁸⁷⁰ In a useful variation, vinyl epoxides react with Grignard reagents and CuBr to give an allylic alcohol via reaction at the $\text{C}=\text{C}$ unit and concomitant opening of the epoxide.⁸⁷¹ Conjugated dienes react with arylmagnesium halides, Ph_3SiCl and a palladium catalyst to give a coupling product involving the reaction of two equivalents of the diene and incorporation of two SiPh_3 units.⁸⁷²

Organolithium reagents (primary, secondary, and tertiary alkyl and in some cases aryl) also add to the double and triple bonds of allylic and propargylic alcohols⁸⁷³ (in this case tetramethylethylenediamine is a catalyst) and to certain other alkenes containing hetero groups, such as OR , NR_2 , or SR . Addition of butyllithium to alkenes has been observed with good enantioselectivity when sparteine was added.⁸⁷⁴ Mixing an organolithium reagent with transition metal compounds, such as CeCl_3 ⁸⁷⁵ or $\text{Fe}(\text{acac})_3$ ⁸⁷⁶ leads to addition of the alkyl group. The intramolecular addition of RLi and R_2CuLi has been reported.⁸⁷⁷ Organolithium reagents

containing an alkene^{377,878} or alkyne⁸⁷⁹ unit cyclize⁸⁸⁰ at low temperatures and quenching with methanol replaces the new C–Li bond with C–H. Cyclopropane derivatives have been formed in this manner.⁸⁸¹ Alkylolithium and alkenylolithium derivatives containing an ester moiety can be cyclized.⁸⁸² Tandem cyclization are possible with dienes and enynes to form more than one ring,⁸⁸³ including bicyclic compounds.⁸⁸⁴ Tandem cyclization is possible with alkyne iodides⁸⁸⁵ or alkynes with a homoallylic CH₂Li unit.⁸⁸⁶ The organolithium reagents can contain heteroatoms, such as nitrogen elsewhere in the molecule, and the organolithium species can be generated from an intermediate organotin derivative.⁸⁸⁷ Organolithium reagents add to the less substituted C=C unit of conjugated dienes.⁸⁸⁸ The organolithium compound can be generated *in situ* by reaction of an organotin compound with butyllithium, allowing cyclization to occur upon treatment with an excess of LiCl.⁸⁸⁹

Ketones with an α -hydrogen add to alkenes, intramolecular, when heated in a sealed tube with CuCl₂ and a palladium catalyst.⁸⁹⁰ A similar reaction was reported using Yb(OTf)₃ and a palladium catalyst.⁸⁹¹ Keto esters add to alkynes using 10% benzoic acid and a palladium catalyst,⁸⁹² or an indium catalyst.⁸⁹³ 1,3-Diketones add to dienes (1,4-addition) using a palladium catalyst,⁸⁹⁴ a AuCl₃/AgOTf catalyst,⁸⁹⁵ and this addition has been done intramolecularly using 2.4 equivalents of CuCl₂ and a palladium catalyst.⁸⁹⁶ A related cyclization reaction was reported for diesters having a remote terminal alkyne unit in the molecule, with a palladium

catalyst.⁸⁹⁷ The intermolecular addition of diesters, such as malonates, to alkynes was accomplished in acetic acid and a palladium catalyst under microwave irradiation.⁸⁹⁸ Enolate anions can add to allylic sulfides, forming β -lactams in some cases.⁸⁹⁹ α -Potassio amines (from an *N*-Boc amine and KHMDS) undergoes intramolecular cyclization with an alkene unit to form a dihydropyrrole.⁹⁰⁰ The enolate anion derived from the reaction of a nitrile with potassium *tert*-butoxide added to the less substituted carbon of the C=C unit of styrene in DMSO.⁹⁰¹ Similarly, the intramolecular addition of a nitrile enolate (from treatment with CsOH in *N*-methylpyrrolidinone) to an alkyne gave a cyclized product with an exocyclic methylene unit.⁹⁰² Silyl enol ethers add to alkynes using a tungsten catalyst.⁹⁰³ Malonate derivatives add to alkenes in the presence of an Al(OR)₃ catalyst.⁹⁰⁴

Unactivated alkenes or alkynes⁹⁰⁵ can react with other organometallic compounds under certain conditions. Trimethylaluminum reacts with 4-methyl-1-pentene, in the presence of Cl₂ZrCp₂, for example, and subsequent reaction with molecular oxygen leads to (2*R*),4-dimethyl-1-pentanol in good yield and 74% ee.⁹⁰⁶ These reagents also add to alkynes.⁹⁰⁷ Aluminum chloride mediated cyclization of α -iodo ketones to a pendant alkyne unit, in the presence of ICl, gave the spirocyclic ketone with an exocyclic C=CHI unit.⁹⁰⁸ Isopropylchloroformate (*i*PrO₂CCl) reacts with an alkene, in conjunction with Et₃Al₂Cl₃, to add an isopropyl group.⁹⁰⁹ Ruthenium catalysts have been used to add allylic alcohols to alkynes.⁹¹⁰ Samarium iodide (SmI₂) induces cyclization of a halide moiety to an alkyne unit⁹¹¹ or an alkene unit⁹¹² to form cyclized products. Copper complexes can catalyze similar cyclization to alkenes, even when an ester unit is present in the molecule.⁹¹³ The reaction of a dithioacetal containing a remote alkene moiety, with a titanium complex, leads to cyclization and incorporation of an endocyclic C=C unit in the final product.⁹¹⁴ Allyl manganese compounds add to allenes to give nonconjugated dienes.⁹¹⁵

Vinyl halides add to allylic amines in the presence of Ni(cod)₂ where cod = 1, 5-cyclooctodine, followed by reduction with sodium borohydride.⁹¹⁶ Aryl iodides add to alkynes using a platinum complex in conjunction with a palladium catalyst.⁹¹⁷ A palladium catalyst has been used alone for the same purpose,⁹¹⁸ and the intramolecular addition of an arene to an alkene was accomplished with a palladium⁹¹⁹ or a GaCl₃ catalyst.⁹²⁰ Alkyl iodides add intramolecularly to alkenes with a titanium catalyst,⁹²¹ or to alkynes using indium metal and additives.⁹²² The latter cyclization of aryl iodides to alkenes was accomplished with indium and iodine⁹²³ or with SmI₂.⁹²⁴

Aromatic hydrocarbons, such as benzene add to alkenes using a ruthenium catalyst⁹²⁵ a catalytic mixture of AuCl₃/AgSbF₆,⁹²⁶ or a rhodium catalyst,⁹²⁷ and ruthenium complexes catalyze the addition of heteroaromatic compounds, such as pyridine, to alkynes.⁹²⁸ Such alkylation reactions are clearly reminiscent of the Friedel–Crafts reaction (11-11). Palladium catalysts can also be used for the addition of aromatic compounds to alkynes,⁹²⁹ and rhodium catalysts for addition to alkenes (with microwave irradiation).⁹³⁰ Note that vinylidene cyclopropanes react with furans and a palladium catalyst to give allylically substituted furans.⁹³¹

Arylboronic acids (p. 905) add to alkynes to give the substituted alkene using a rhodium catalyst.⁹³² Allenes react with phenylboronic acid and an aryl iodide, in the presence of a palladium catalyst, to give a substituted alkene.⁹³³ 2-Bromo-1,6-dienes react with phenylboronic acid with a palladium catalyst to give a cyclopentane with an exocyclic double bond and a benzyl substituent.⁹³⁴

Organomanganese reagents add to alkenes.⁹³⁵ Manganese triacetate [Mn(OAc)₃], in the presence of cupric acetate, facilitates intramolecular cyclization of a halide unit to an alkene.⁹³⁶ A combination of Mn(OAc)₂ and Co(OAc)₂ catalysts, and an oxygen atmosphere in acetic acid, leads to addition of ketones to simple alkenes, give the 2-alkyl ketone.⁹³⁷ Alkynes react with indium reagents, such as (allyl)₃In₂I₃, to form dienes (allyl substituted alkenes from the alkyne).⁹³⁸ Allylic halides add to propargyl alcohols using indium metal to form the aryl organometallic *in situ*.⁹³⁹ Allyltin reagents add to alkynes in a similar manner in the presence of ZrCl₄.⁹⁴⁰ Alkylzinc reagents add to alkynes to give substituted alkenes in the presence of a palladium catalyst.⁹⁴¹ Allylzinc reagents add to alkynes in the presence of a cobalt catalyst.⁹⁴² A variation reacts dialkylzinc compounds with a 7-oxabicyclo[2.2.1]hept-2-ene system to give incorporation of the alkyl group and opening of the ring to give a cyclohexenol derivative.⁹⁴³ Vinyltellurium add to alkynes in the presence of CuI/PdCl₂.⁹⁴⁴

An indirect addition converts alkynes to an organozinc compound using a palladium catalyst, which then reacts with allylic halides.⁹⁴⁵ Similarly, the reaction of an alkyne with Ti(O*i*Pr)₄/2 *i*PrMgCl followed by addition of an alkyne leads to a conjugated diene.⁹⁴⁶

OS 81, 121.

15-22 The Addition of Two Alkyl Groups to an Alkyne

Dialkyl-addition

Two different alkyl groups can be added to a terminal alkyne⁹⁴⁷ in one laboratory step by treatment with an alkylcopper-magnesium bromide reagent (called *Normant*

reagents)⁹⁴⁸ and an alkyl iodide in ether-HMPA containing triethyl phosphite.⁹⁴⁹ The groups add stereoselectively syn. The reaction, which has been applied to primary⁹⁵⁰ R' and to primary, allylic, benzylic, vinylic, and α -alkoxyalkyl R', involves initial addition of the alkylcopper reagent,⁹⁵¹ followed by a coupling reaction (10-57):

Acetylene itself (R = H) undergoes the reaction with R₂CuLi instead of the Normant reagent.⁹⁵² The use of R' containing functional groups has been reported.⁹⁵³ If the alkyl iodide is omitted, the vinylic copper intermediate

136 can be converted to a carboxylic acid by the addition of CO₂ (see 16-30) or to an amide by the addition of an isocyanate, in either case in the presence of HMPA and a catalytic amount of triethyl phosphite.⁹⁵⁴ The use of I₂ results in a vinylic iodide.⁹⁵⁵

Similar reactions, in which two alkyl groups are added to a triple bond, have been carried out with trialkylalanes (R₃Al), with zirconium complexes as catalysts.⁹⁵⁶ Allyl ethers and iodobenzene have also been added using a

zirconium complex.⁹⁵⁷ Similarly, allyl ethers and allyl chlorides have been added.⁹⁵⁸

Allylic zinc bromides add to vinylic Grignard and lithium reagents to give the gem-dimetallo compounds **137**. The two metallo groups can be separately reacted with various nucleophiles.⁹⁵⁹

Arylboronic acids (p. 905) react with alkynes and 1 equivalent of an aryl iodide, with a palladium catalyst, to add two aryl groups across the triple bond.⁹⁶⁰

OS VII, 236, 245, 290.

15-23 The Ene Reaction

Hydro-allyl-addition

Alkenes can add to double bonds in a reaction different from those discussed in **15-20**, which, however, is still formally the addition of RH to a double bond. This is called the *ene reaction* or the *ene synthesis*.⁹⁶¹ For the reaction to proceed without a catalyst, one of the components must be a reactive dienophile (see **15-60** for a definition of this word), such as maleic anhydride, but the other (which supplies the hydrogen) may be a simple alkene such as propene. Rather high reaction temperatures (250–450°C) are common unless the substrates are very

activated. Note that steric acceleration of the uncatalyzed ene reaction is known.⁹⁶² Cyclopropene has also been used.⁹⁶³ The reaction is compatible with a variety of functional groups that can be appended to the ene and dienophile.⁹⁶⁴ *N,N*-Diallyl amides give an ene cyclization, for example.⁹⁶⁵ The ene reaction is known with fullerene (see p. 94) derivatives.⁹⁶⁶ There has been much discussion of the mechanism of this reaction, and both concerted pericyclic (as shown above) and stepwise

mechanisms have been suggested. The mechanism of the ene reaction of singlet ($^1\Delta_g$) oxygen with simple alkenes was found to involve two steps, with no intermediate.⁹⁶⁷ A retro-ene reaction is known with allylic dithiocarbonate.⁹⁶⁸ The reaction between maleic anhydride and optically active $\text{PhCHMeCH}=\text{CH}_2$ gave an optically active product (**138**),⁹⁶⁹ which is strong evidence for a concerted rather than a stepwise mechanism.⁹⁷⁰ The reaction can be highly stereoselective.⁹⁷¹

The reaction can be extended to less-reactive enophiles by the use of Lewis acid catalysts, especially alkylaluminum halides.⁹⁷² Titanium catalysts,⁹⁷³ $\text{Sc}(\text{OTf})_3$,⁹⁷⁴

and sulfones, as well as other compounds with relatively acidic hydrogens, such as indenenes and fluorenes. Vinylogous Michael reaction are well known, using a variety of nucleophilic species.¹⁰⁰⁵ Michael addition of methyl 2,2-dichloroacetate/LiN(TMS)₂ where TMS = trimesitylsilyl, leads to formation of a cyclopropane ring.¹⁰⁰⁶ Similarly, the intramolecular Michael addition of an α -chloro ketone enolate anion, formed *in situ* using DABCO, leads to formation of a bicyclo[4.1.0] diketone.¹⁰⁰⁷ It is noted that activated aryl compounds undergo Michael addition in the presence of an imidazolidinone catalyst.¹⁰⁰⁸ Conjugate addition of nitrones using SmI₂ has been reported.¹⁰⁰⁹

These reagents do not add to ordinary double bonds, except in the presence of free-radical initiators (15-33). 1,2 Addition (to the C=O or C \equiv N group) often competes and sometimes predominates (16-38).¹⁰¹⁰ In particular, α,β -unsaturated aldehydes seldom give 1,4 addition.¹⁰¹¹ The Michael reaction has traditionally been performed in protic solvents, with catalytic amounts of base,¹⁰¹² but more recently better yields with fewer side reactions have been obtained in some cases by using an equimolar amount of base to convert the nucleophile to its enolate form (*performed enolate*). In particular, preformed enolates are often used where stereoselective reactions are desired.¹⁰¹³ Silyl enol ethers can also be used, and in conjunction with chiral additives.¹⁰¹⁴ Phase-transfer catalysts have been used,¹⁰¹⁵ and ionic liquids have been used in conjunction with phase-transfer catalysis.¹⁰¹⁶ Michael addition has been done in ionic liquids, adding aldehydes to conjugated nitro compounds using proline as a catalyst.¹⁰¹⁷ Transition-metal compounds, such as CeCl₃,¹⁰¹⁸ Yb(OTf)₃,¹⁰¹⁹ Bi(OTf)₃,¹⁰²⁰ ferric chloride hexahydrate,¹⁰²¹

copper compounds,¹⁰²² lanthanum complexes,¹⁰²³ ruthenium complexes,¹⁰²⁴ or scandium complexes¹⁰²⁵ also induce the reaction. In many cases, such compounds lead to catalytic enantioselective Michael additions.¹⁰²⁶ Conjugate addition has also been promoted by Y-zeolite,¹⁰²⁷ and water-promoted Michael additions have also been reported.¹⁰²⁸ Other catalysts have also been used.¹⁰²⁹ Vinylzinc complexes add to conjugated ketones in the presence of a CuBr catalyst.¹⁰³⁰

In a Michael reaction with suitably different R groups, two new stereogenic centers are created (see **139**).

In a diastereoselective process, one of the two pairs is formed exclusively or predominantly, as a racemic mixture.¹⁰³¹ Many such examples have been reported.⁶⁷² In many of these cases, both the enolate anion and substrate can exist as (*Z*) or (*E*) isomers. With enolates derived from ketones or carboxylic esters, The (*E*) enolates gave the syn pair of enantiomers (p. 166), while (*Z*) enolates gave the anti pair.¹⁰³² Nitro compounds add to conjugated ketones in the presence of a dipeptide and a piperazine.¹⁰³³ Malonate derivatives also add to conjugated ketones,¹⁰³⁴ and keto esters add to conjugated esters.¹⁰³⁵ Addition of chiral additives to the reaction, such as metal–salen complexes,¹⁰³⁶ proline derivatives,¹⁰³⁷ or (–)-sparteine,¹⁰³⁸

lead to product formation with good-to-excellent asymmetric induction. Ultrasound has also been used to promote asymmetric Michael reactions.¹⁰³⁹ Intramolecular versions of Michael addition are known.¹⁰⁴⁰ A double Michael process is possible, where conjugate addition to an alkynyl ketone is followed by an intramolecular Michael to form a functionalized ring.¹⁰⁴¹

When either or both of the reaction components has a chiral substituent, the reaction can be enantioselective (only one of the four diastereomers formed predominantly).¹⁰⁴² Enantioselective addition has also been achieved by the use of a chiral catalyst¹⁰⁴³ and by using optically active enamines instead of enolates.¹⁰⁴⁴ Chiral imines have also been used.¹⁰⁴⁵

Mannich bases (see **16-19**) and β -halo carbonyl compounds can also be used as substrates; these are converted to the $C=C-Z$ compounds *in situ* by the base (**16-19**, **17-13**).¹⁰⁴⁶ Substrates of this kind are especially useful in cases where the $C=C-Z$ compound is unstable. The reaction of $C=C-Z$ compounds with enamines (**10-69**) can also be considered a Michael reaction. Michael reactions are reversible.

When the substrate contains *gem-Z* groups (e.g., **141**), bulky groups can be added, if the reaction is carried out under aprotic conditions. For example, addition of enolate **140** to **141** gave **142** in which two adjacent quaternary centers have been formed.¹⁰⁴⁷

¹⁰⁴⁶Mannich bases react with ketones *without* basic catalysts to give 1,5-diketones, but this process, known as the *thermal-Michael reaction*, has a different mechanism: Brown, H.L.; Buchanan, G.L.; Curran, A.C.W.; McLay, G.W. *Tetrahedron* **1968**, *24*, 4565; Gill, N.S.; James, K.B.; Lions, F.; Potts, K.T. *J. Am. Chem. Soc.* **1952**, *74*, 4923.

¹⁰⁴⁷Holton, R.A.; Williams, A.D.; Kennedy, R.M. *J. Org. Chem.* **1986**, *51*, 5480.

In certain cases, Michael reactions can take place under acidic conditions.¹⁰⁴⁸ Michael-type addition of radicals to conjugated carbonyl compounds is also known.¹⁰⁴⁹ Radical addition can be catalyzed by $\text{Yb}(\text{OTf})_3$,¹⁰⁵⁰ but radicals add under standard conditions as well, even intramolecularly.¹⁰⁵¹ Electrochemical-initiated Michael additions are known.

Michael reactions are sometimes applied to substrates of the type $\text{C}\equiv\text{C}-\text{Z}$, where the coproducts are conjugated systems of the type $\text{C}=\text{C}-\text{Z}$.¹⁰⁵² Indeed, because of the greater susceptibility of triple bonds to nucleophilic attack, it is even possible for nonactivated alkynes (e.g., acetylene), to be substrates in this reaction.¹⁰⁵³

In a closely related reaction, silyl enol ethers add to α,β -unsaturated ketones and esters when catalyzed¹⁰⁵⁴ by TiCl_4 , for example,¹⁰⁵⁵

InCl_3 also catalyzes this reaction.¹⁰⁵⁶ Aluminum compounds also catalyze this reaction¹⁰⁵⁷ and the reaction has been done in neat tri-*n*-propylaluminum.¹⁰⁵⁸ A solid-state version of the reaction used alumina• ZnCl_2 .¹⁰⁵⁹ This reaction, also, has been performed diastereoselectively.¹⁰⁶⁰ Tin enolates have been used.¹⁰⁶¹

15-25 1,4 Addition of Organometallic Compounds to Activated Double Bonds

Hydro-alkyl-addition

Lithium dialkylcopper reagents (see **10-57**) add to α,β -unsaturated aldehydes¹⁰⁶² and ketones ($\text{R}' = \text{H}, \text{R}, \text{Ar}$) to give conjugate addition products¹⁰⁶³ in a reaction closely related to the Michael reaction. α,β -Unsaturated esters are less reactive,¹⁰⁶⁴ and the corresponding acids do not react at all. R can be primary alkyl, vinylic,¹⁰⁶⁵ or aryl. If Me_3SiCl is present, the reaction takes place much faster and with higher yields; in this case the product is the silyl enol ether of **143** (see **12-17**).¹⁰⁶⁶ The use of Me_3SiCl also permits good yields with allylic R groups.¹⁰⁶⁷ Conjugated alkenyl-ketones also react via 1,4-addition to give substituted alkenyl-ketones.¹⁰⁶⁸

Various functional groups, such as OH and unconjugated $\text{C}=\text{O}$ groups, may be present in the substrate.¹⁰⁶⁹ Conjugated sulfones are also good substrates.¹⁰⁷⁰ An excess of the cuprate reagent relative to the conjugated substrate is often required. In general, only one of the R groups of R_2CuLi adds to the substrate; the other is wasted. This can be a limitation where the precursor (RLi or RCu, see **12-36**) is expensive or available in limited amounts, particularly if an excess of the reagent

is required. The difficulty of group transfer can be overcome by using one of the mixed reagents $R(R'C\equiv C)CuLi$,¹⁰⁷¹ $R(O-t-Bu)CuLi$,¹⁰⁷² $R(PhS)CuLi$,¹⁰⁷³ each of which transfers only the R group. Mixed reagents are easily prepared by the reaction of RLi with $R'C\equiv CCu$ ($R' = n-Pr$ or $t-Bu$), $t-BuOCu$, or $PhSCu$, respectively. A further advantage of the mixed reagents is that good yields of addition product are achieved when R is tertiary, so that use of one of them permits the introduction of a tertiary alkyl group. The mixed reagents $R(CN)CuLi$ ¹⁰⁷⁴ (prepared from RLi and CuCN) and $R_2Cu(CN)Li_2$ ¹⁰⁷⁵ also selectively transfer the R group.¹⁰⁷⁶ Other mixed reagents incorporate a ligand that is not easily transferred, such as $R(R'Se)Cu(CN)Li_2$, leading to selective transfer of the R group.¹⁰⁷⁷ The reaction has also been carried out¹⁰⁷⁸ with α,β -acetylenic ketones,¹⁰⁷⁹ esters, and nitriles.

Both Grignard and R_2CuLi reagents¹⁰⁸⁰ have also been added to systems of the form $C\equiv C-C=O$.¹⁰⁸¹ Conjugate addition to α,β -unsaturated and acetylenic acids and esters, as well as ketones, can be achieved by the use of the coordinated reagents $RCu\bullet BF_3$ ($R = \text{primary}$).¹⁰⁸² Alkylcopper compounds RCu ($R = \text{primary}$ or secondary alkyl) have also been used with tetramethylethylenediamine and Me_3SiCl to give silyl enol ethers from α,β -unsaturated ketones in high yield.¹⁰⁸³ Amine units have been transferred in this manner using α -lithio amides, CuCN, and additives ranging from LiCl to $Me_2NCH_2SnBu_3$, which gave conjugate addition of an amidomethyl unit, $-CH_2N(Me)Boc$.¹⁰⁸⁴ Other amino-cuprates are known to give conjugate addition reactions.¹⁰⁸⁵

¹⁰⁸⁵Yamamoto, Y.; Asao, N.; Uyehara, T. *J. Am. Chem. Soc.* **1992**, *114*, 5427.

There is generally little or no competition from 1,2-addition (to the C=O). However, when R is allylic, 1,4-addition is observed with some substrates and 1,2-addition with others.¹⁰⁸⁶ R₂CuLi also add to α,β-unsaturated sulfones¹⁰⁸⁷ but not to simple α,β-unsaturated nitriles.¹⁰⁸⁸ Organocopper reagents (RCu), as well as certain R₂CuLi add to α,β-unsaturated and acetylenic sulfoxides.¹⁰⁸⁹

Conjugate addition of the cuprate to the α,β-unsaturated ketone leads to an enolate ion, **143**. It is possible to have this enolate anion reacts with an electrophilic species (*tandem vicinal difunctionalization*), in some cases at the O and in other cases at the C.¹⁰⁹⁰ For example, if an alkyl halide R²X is present (R² = primary alkyl or allylic), the enolate **143** can be alkylated directly.¹⁰⁹¹ Thus, by this method, both the α and β positions of a ketone are alkylated in one synthetic operation (see also, **15-22**).

As with the Michael reaction (**15-24**) the 1,4-addition of organometallic compounds has been performed diastereoselectively¹⁰⁹² and enantioselectively.¹⁰⁹³

The influence of solvent and additives on yield and selectivity has been examined.¹⁰⁹⁴ The conjugate addition of dimethyl cuprate in the presence of a chiral ligand, such as **144**, is an example.¹⁰⁹⁵ The use of chiral ligands with MgI₂/I₂ and Bu₃SnI gave conjugate addition products with α,β -unsaturated amides with good % ee.¹⁰⁹⁶ Chiral bis(oxazoline) copper catalysts have been used for the conjugate addition of indoles to α,β -unsaturated esters.¹⁰⁹⁷ Chiral templates have also been used with Grignard reagents, directly¹⁰⁹⁸ and in the presence of AlMe₂Cl.¹⁰⁹⁹ Many of the examples cited below involve the use of chiral additives, chiral catalysts, or chiral templates.

Grignard reagents also add to conjugated substrates such as α,β -unsaturated ketones, cyano-ketones,¹¹⁰⁰ esters, and nitriles,¹¹⁰¹ but 1,2-addition may seriously compete:¹¹⁰² The product is often controlled by steric factors. Thus **145** with phenylmagnesium bromide gives 100% 1,4-addition, while **146** gives 100% 1,2-addition. In general, substitution at the carbonyl group increases 1,4-addition, while substitution at the double bond increases 1,2-addition. In most cases, both products are obtained, but α,β -unsaturated aldehydes nearly always give exclusive 1,2-addition when treated with Grignard reagents. However, the extent of 1,4-addition of Grignard reagents can be increased by the use of a copper ion catalyst, for example, CuCl, Cu(OAc)₂.¹¹⁰³ A dialkyl copper–magnesium iodide complex (R₂Cu•MgI) has been used for conjugate addition to chiral α,β -unsaturated amides.¹¹⁰⁴ Grignard reagents mixed with CeCl₃ generates a reactive species that gives primarily 1,4-addition.¹¹⁰⁵ It is likely that alkylcopper reagents, formed from RMgX and

Cu^+ (cupric acetate is reduced to cuprous ion by excess RMgX), are the actual attacking species in these cases.¹⁰⁶³ Alkylidene malonic ester derivatives, $\text{C}=\text{C}(\text{CO}_2\text{R})$, increase the facility of 1,4-addition with the two electron withdrawing groups.¹¹⁰⁶ Alkylidene amido esters, $\text{C}=\text{C}(\text{CO}_2\text{R})\text{NHCOAr}$, react with $\text{EtI}/\text{Mg}(\text{ClO}_4)_2$ and Bu_3SnH , in the presence of BEt_3/O_2 and a chiral ligand, to give the ethylated product $\text{EtCHCH}(\text{CO}_2\text{R})\text{NHCOAr}$.¹¹⁰⁷ This is probably a radical process (see 15-35).

Organolithium reagents¹¹⁰⁸ generally react with conjugated aldehydes, ketones and esters by 1,2-addition,¹¹⁰⁹ but 1,4-addition was achieved with esters of the form $\text{C}=\text{C}-\text{COOAr}$, where Ar was a bulky group such as 2,6-di-*tert*-butyl-4-methoxyphenyl.¹¹¹⁰ Alkylolithium reagents can be made to give 1,4-addition with α,β -unsaturated ketones¹¹¹¹ and aldehydes¹¹¹² if the reactions are conducted in the presence of HMPA.¹¹¹³ Among organolithium reagents that have been found to add 1,4 in this manner are 2-lithio-1,3-dithianes (see 10-71),¹¹¹⁴ vinylolithium reagents,¹¹¹⁵ and α -lithio allylic amides.¹¹¹⁶ Lithium-halogen exchange (12-22) generates an organolithium species that adds intramolecularly to conjugated esters to give cyclic and bicyclic products.¹¹¹⁷ 1,4-Addition of alkylolithium reagents to α,β -unsaturated aldehydes can also be achieved by converting the aldehyde to a benzothiazole derivative (masking the aldehyde function),¹¹¹⁸ from which the aldehyde group can be regenerated. When some conjugated acids are added to organolithium reagents, the conjugate addition product was isolated in good yield.¹¹¹⁹ α,β -Unsaturated nitro compounds undergo conjugate addition with aryllithium reagents, and subsequent treatment with acetic acid gives the α -aryl ketone.¹¹²⁰

If the organolithium reagent is modified, 1,4-addition is more successful. The reaction of an aryllithium reagent with $B(OMe)_3$, for example, led to a rhodium-catalyzed conjugate addition with excellent enantioselectivity in when a chiral ligand was employed.¹¹²¹ Allylic tellurium reagents that are treated with lithium diisopropyl amide, and then conjugated esters give the 1,4-addition product, which cyclizes to form the corresponding cyclopropane derivative.¹¹²²

Boron reagents add to conjugated carbonyl compounds.¹¹²³ Alkynyl borate esters (p. 815) give conjugate addition in the presence of boron trifluoride etherate,¹¹²⁴ as do arylboronic acids (p. 815) with a rhodium,¹¹²⁵ palladium,¹¹²⁶ or a bismuth catalyst.¹¹²⁷ Diethylzinc has also been used.¹¹²⁸ Aryl boronic acids add to the double bond of vinyl sulfones in the presence of a rhodium catalyst.¹¹²⁹ Similarly, $LiBPh(OMe)_3$ and a rhodium catalyst gave conjugate addition of the phenyl group to α,β -unsaturated esters.¹¹³⁰ Potassium vinyltrifluoroborates (see p. 607) give 1,4-addition with a rhodium catalyst,¹¹³¹ as do aryltrifluoroborates.¹¹³²

Organozinc compounds add to conjugated systems. The use of chiral ligands is effective for conjugate addition of dialkylzinc compounds to α,β -unsaturated ketones, esters, and so on,¹¹³³ including conjugated lactones.¹¹³⁴ Many dialkylzinc compounds can be used, including vinylzinc compounds.¹¹³⁵ Dialkylzinc

of palladium acetate, to give the 2-alkenyl pyrrole.¹¹⁶⁵

In certain cases, Grignard reagents add 1,4 to *aromatic* systems to give **147** after tautomerization (p. \$\$\$) of the initial formed enol.¹¹⁶⁶ Such cyclohexadienes are easily oxidizable to benzenes (often by atmospheric oxygen), so this reaction becomes a method of alkylating and arylating suitably substituted (usually hindered) aryl ketones. A similar reaction has been reported for aromatic nitro compounds where 1,3,5-trinitrobenzene reacts with excess methylmagnesium halide to give 2,4,6-trinitro-1,3,5-trimethylcyclohexane.¹¹⁶⁷

The mechanisms of most of these reactions are not well known. The 1,4 uncatalyzed Grignard reaction has been postulated to proceed by the cyclic mechanism shown, but there is evidence against it.¹¹⁶⁸ The R₂CuLi¹¹⁶⁹ and copper-catalyzed Grignard additions may involve a number of mechanisms, since the actual attacking species and substrates are so diverse.¹¹⁷⁰ A free-radical mechanism of some type

(perhaps SET) has been suggested¹¹⁷¹ although the fact that retention of configuration at R has been demonstrated in several cases rules out a completely free R• radical.¹¹⁷² For simple α,β -unsaturated ketones, such as 2-cyclohexenone, and Me_2CuLi , there is evidence¹¹⁷³ for this mechanism:

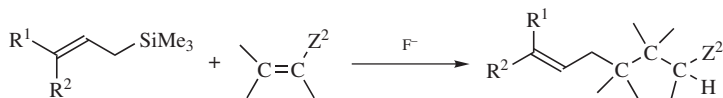

148 is a d,π^* complex, with bonding between copper, as a base supplying a pair of d electrons, and the enone as a Lewis acid using the π^* orbital of the allylic system.¹¹⁷³ The ^{13}C NMR spectrum of an intermediate similar to **148** has been reported.¹¹⁷⁴

For the addition of organocopper reagents to alkynes and conjugated dienes, see **15-22**.

15-26 The Sakurai Reaction

Allylic silanes $\text{R}_2\text{C}=\text{CHCH}_2\text{SiMe}_3$ can be used instead of silyl enol ethers (the *Sakurai reaction*).¹¹⁷⁵ An allyl group can be added, to α,β -unsaturated carboxylic esters, amides and nitriles, with $\text{CH}_2=\text{CHCH}_2\text{SiMe}_3$ and F^- ion (see **15-47**).¹¹⁷⁶ This reagent gave better results than lithium diallylcuprate (**15-25**). Catalytic Sakurai reactions are known.¹¹⁷⁷ The palladium catalyzed reaction of conjugated ketones with $\text{PhSi}(\text{OEt})_3$ with SbCl_3 and Bu_4NF in acetic acid gave the 1,4-addition product.¹¹⁷⁸ A similar reaction was reported using $\text{PhSi}(\text{OMe})_3$

with a rhodium catalyst.¹¹⁷⁹ In a related reaction, Ph_2SiCl_2 , NaF and a rhodium catalyst gives conjugate addition of a phenyl group to α,β -unsaturated ketones.¹¹⁸⁰ An interesting rhodium-catalyzed, conjugate addition of a phenyl group was reported using a siloxane polymer bearing Si-Ph units.¹¹⁸¹

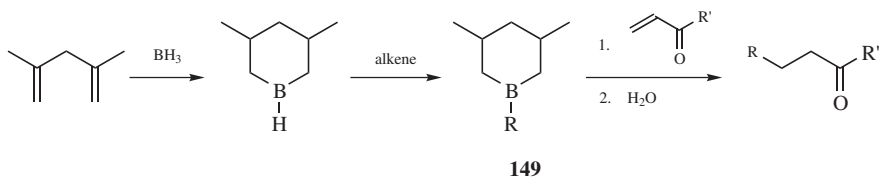

Silyl ketene acetals, $\text{RCH}=\text{C}(\text{OMe})\text{OSiMe}_3$, add to conjugated ketones to give δ -keto esters, in MeNO_2 as solvent.¹¹⁸²

15-27 Conjugate Addition of Boranes to Activated Double Bonds

Hydro-alkyl-addition (overall transformation)

Just as trialkylboranes add to simple alkenes (15-16), they rapidly add to the double bonds of acrolein, methyl vinyl ketone, and certain of their derivatives in THF at 25°C to give enol borinates (also see, p. 631), which can be hydrolyzed to aldehydes or ketones.¹¹⁸³ If water is present in the reaction medium from the beginning, the reaction can be run in one laboratory step. Since the boranes can be prepared from alkenes (15-16), this reaction provides a means of lengthening a carbon chain by three or four carbons, respectively. Compounds containing a terminal alkyl group, such as crotonaldehyde ($\text{CH}_3\text{CH}=\text{CHCHO}$) and 3-penten-2-one, fail to react under these conditions, as does acrylonitrile, but these compounds can be induced to react by the slow and controlled addition of O_2 or by initiation with peroxides or UV light.¹¹⁸⁴ A disadvantage is

¹¹⁸⁴Brown, H.C.; Kabalka, G.W. *J. Am. Chem. Soc.* **1970**, *92*, 712, 714. See also, Utimoto, K.; Tanaka, T.; Furubayashi, T.; Nozaki, H. *Tetrahedron Lett.* **1973**, 787; Miyaura, N.; Kashiwagi, M.; Itoh, M.; Suzuki, A. *Chem. Lett.* **1974**, 395.

that only one of the three R groups of R_3B adds to the substrate, so that the other two are wasted. This difficulty is overcome by the use of a β -alkyl borinate, such as **149**,¹¹⁸⁵ which can be prepared as shown. **149** ($R = \textit{tert}$ -butyl) can be made by treatment of **149** ($R = \text{OMe}$) with $t\text{-BuLi}$. The use of this reagent permits \textit{tert} -butyl groups to be added. β -1-Alkenyl-9-BBN compounds $\beta\text{-RCH}=\text{CR}'\text{-9-BBN}$ (prepared by treatment of alkynes with 9-BBN or of $\text{RCH}=\text{CR}'\text{Li}$ with β -methoxy-9-BBN¹¹⁸⁶) add to methyl vinyl ketones to give, after hydrolysis, γ,δ -unsaturated ketones,¹¹⁸⁷ although $\beta\text{-R-9-BBN}$, where $R =$ a saturated group, are not useful here, because the R group of these reagents does not preferentially add to the substrate.¹¹⁸⁴ The corresponding β -1-alkynyl-9-BBN compounds also give the reaction.¹¹⁸⁸ Like the three substrates mentioned above, 3-butyn-2-one fails to react in the absence of air, but undergoes the reaction when exposed to a slow stream of air.¹¹⁸⁹ Since the product, **150**, is an α,β -unsaturated ketone, it can be made to react with another BR_3 , the same or different, to produce a wide variety of ketones **151**.

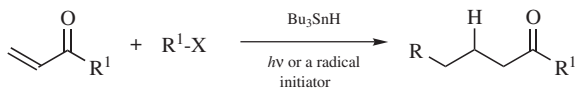

Vinyl boranes add to conjugated ketones in the presence of a rhodium catalyst (with high asymmetric induction in the presence of BINAP).¹¹⁹⁰ Alkynyl-boranes also add to conjugated ketones, in the presence of BF_3 .¹¹⁹¹

The fact that these reactions are catalyzed by free-radical initiators and inhibited by galvinoxyl¹¹⁹² (a free-radical inhibitor) indicates that free-radical mechanisms are involved.

In a reaction similar to **15-25**, alkyl groups can be added to alkenes activated by, such groups as COR', COOR', CN, and even Ph.¹¹⁹³ In the method illustrated above, the R group comes from an alkyl halide (R = primary, secondary, or tertiary alkyl; X = Br or I) and the hydrogen from the tin hydride. The reaction of *tert*-butyl bromide, Bu₃SnH and AIBN (p. 935), for example, adds a *tert*-butyl group to a conjugated ester via 1,4-addition.¹¹⁹⁴ An alkene is converted to an alkylborane with catecholborane (p. 817) and when treated with a conjugated ketone and O₂, radical conjugate addition leads to the β-substituted ketone.¹¹⁹⁵ Organomercury hydrides (RHgH) generated *in situ* from RHgX and NaBH₄, can also be used.¹¹⁹⁶ When the tin method is used, Bu₃SnH can also be generated in a similar way, from R₃SnX and NaBH₄. The tin method has a broader scope (e.g., it can be used on CH₂=CCl₂), but the mercury method uses milder reaction conditions. Like **15-27**, these additions have free-radical mechanisms. The reaction has been used for free-radical cyclizations of the type discussed on p. 1125.¹¹⁹⁷ Such cyclizations normally give predominant formation of 15-membered rings, but large rings (11–20 members) have also been synthesized by this reaction.¹¹⁹⁸

Free-radical addition of an aryl group and a hydrogen has been achieved by treatment of activated alkenes with a diazonium salt and TiCl₃.¹¹⁹⁹ The addition of R₃Al takes place by a free-radical mechanism.¹¹⁴⁶

Radical addition to alkenes is usually difficult, except when addition occurs to conjugated carbonyl compounds (15-24). An important exception involves radicals bearing a heteroatom α to the carbon bearing the radical center. These radical are much more stable and can add to alkenes, usually with anti-Markovnikov orientation, as in the radical induced addition of HBr to alkenes (15-2).¹²⁰¹ Examples of this type of reaction include the use of alcohol-, ester-,¹²⁰² amino-, and aldehyde-stabilized radicals.⁴⁵⁵ Carbon tetrachloride can be cleaved homolytically to generate $\text{Cl}\cdot$ and $\text{Cl}_3\text{C}\cdot$, which can add to alkenes. The alkyl group of alkyl iodides adds to alkenes with BEt_3/O_2 as the initiator and in the presence of a tetraalkylammonium hypophosphite.¹²⁰³ When chloroform was treated with a ruthenium carbene complex, $\text{Cl}_2\text{CH}\cdot$ add to the less substituted carbon of an alkene, and $\text{Cl}\cdot$ to the more substituted carbon.¹²⁰⁴ The radical generated from $(\text{EtO})_2\text{POCH}_2\text{Br}$ adds to alkenes to generate a new phosphonate ester.¹²⁰⁵ α -Bromo esters add to alkenes in the presence of BEt_3/air to give a γ -bromo ester.¹²⁰⁶ α -Bromo amides add the Br and the acyl carbon to an alkene using $\text{Yb}(\text{OTf})_3$ with BEt_3/O_2 as the radical initiator.¹²⁰⁷ α -Iodo amides add to alkenes using a water soluble azobis initiator to give the iodo ester, which cyclizes under the reaction conditions to give a lactone.¹²⁰⁸ β -Keto dithiocarbonates, $\text{RC}(=\text{O})\text{—C—SC}(=\text{S})\text{OEt}$, generate the radical in the presence of a peroxide and add to alkenes.¹²⁰⁹ Malonate derivatives add to alkenes in the presence of a mixture of Mn/Co catalyst, in oxygenated acetic acid.¹²¹⁰

Other radicals can add to alkenes, and the rate constant for the addition of methyl radicals to alkenes has been studied,¹²¹¹ and the rate of radical additions to alkenes in general has also been studied.¹²¹² The kinetic and thermodynamic control of a radical addition regiochemistry has also been studied.¹²¹³ Alkynes are generally less reactive than alkenes in radical coupling reactions.¹²¹⁴ Nonradical nucleophiles usually react faster with alkynes than with alkenes, however.¹²¹⁵

15-30 Radical Cyclization¹²¹⁶

Alkyl-hydro-addition

ω -Haloalkenes generate radicals upon treatment with reagents, such as AIBN or under photolysis conditions,¹²¹⁷ and the radical carbon adds to the alkene to form cyclic compounds.¹²¹⁸ This intramolecular addition of a radical to an alkene is called radical cyclization. In a typical example, haloalkene **154** reacts with the radical produced by AIBN to give radical **153**. The radical can add to the more substituted carbon to give **155** via a 5-exo-trig reaction (p. 305).¹²¹⁹ If the radical adds to the less substituted carbon, **156** is formed via a 6-endo-trig reaction.¹²²⁰ In both cases, the product is another radical, which must be converted to an unreactive product. This is generally accomplished by adding a hydrogen transfer agent,¹²²¹ such as tributyltin hydride (Bu_3SnH), which reacts with **155** to form methylcyclopentane and $\text{Bu}_3\text{Sn}\cdot$, or with **156** to give cyclohexane. The $\text{Bu}_3\text{Sn}\cdot$ formed in both cases usually dimerizes to form $\text{Bu}_3\text{SnSnBu}_3$. Cyclization can compete with hydrogen transfer¹²²² of Bu_3SnH to **153** to give **152**, the reduction product. In general, formation of the five-membered ring dominates the cyclization, but if addition to the $\text{C}=\text{C}$ unit is relatively slow, the reduction product is formed preferentially. Radical rearrangements can also diminish the yield of the desired product.¹²²³ Given a choice between a larger and a smaller ring, radical cyclization generally gives the smaller ring,¹²²⁴ but not

always.¹²²⁵ The mechanism of this reaction has been discussed.¹²²⁶ Formation of other size rings is possible of course. A 4-exo-trig radical cyclization has been studied,¹²²⁷ selectivity in a 7-endo versus 6-exo cyclization,¹²²⁸ and also an 8-endo-trig reaction.¹²²⁹ In radical cyclization to form large rings, 1,5- and 1,9-hydrogen atom abstractions can pose a problem¹²³⁰

In cases where hydrogen atom transfer gives primarily reduced products, $\text{Bu}_3\text{Sn-SnBu}_3$ under photochemical generates the radical which can cyclize (see **15-46**),¹²³¹ but a halogen atom transfer agent, such as iodoethane, is used rather than a hydrogen-transfer agent, so the final product is an alkyl iodide.

A mixture of a Grignard reagent and CoCl_2 has also been used to initiate aryl radical cyclizations.¹²³² Titanium(III)-mediated radical cyclizations are known,¹²³³ and SmI_2 -mediate reactions are possible in the presence of a nickel catalyst.¹²³⁴ Organoborane-mediated radical cyclizations are known.¹²³⁵ Electrochemically generated radicals also cyclize.¹²³⁶ The influence of the halogen atom on radical cyclization has been studied.¹²³⁷ Both phenylthio¹²³⁸ and phenylseleno

groups¹²³⁹ can be used as 'leaving groups' for radical cyclization, where sulfur or selenium atom transfer leads to formation of the radical. A seleno ester, $R_2N-CH_2C(O)SeMe$, has also been used with $(Me_3Si)_3SiH$ (tristrimethylsilylsilane, TTMSS) and AIBN to generate $R_2NCH_2\cdot$.¹²⁴⁰ *O*-Phosphonate esters have also served as the leaving group.¹²⁴¹ *N*-(2-bromophenylbenzyl)methylamino groups have been used as leaving groups for formation of a radical.¹²⁴² Alkenes also serve as radical precursors, adding to another alkene,¹²⁴³ including conjugated systems.¹²⁴⁴

Radical cyclization reaction often proceeds with high diastereoselectivity¹²⁴⁵ and high asymmetric induction when chiral precursors are used. Internal alkynes are good substrates for radical cyclization,¹²⁴⁶ but terminal alkynes tend to give mixtures of *exo/endo-dig* products (p. 305).¹²⁴⁷ *N*-Alkenyl pyridinium salts, with ortho-halogen substituents generate the aryl radical with $Bu_3SnH/AIBN$, which cyclizes on the pendant alkene unit.¹²⁴⁸ Cyclization of vinyl radicals¹²⁴⁹ and allenyl radicals¹²⁵⁰ are also well known. Ring expansion during radical cyclization is possible when the terminal intermediate is a cyclobutylcarbinyl radical.¹²⁵¹

Aryl radicals participate in radical cyclization reactions when the aromatic ring has an alkene or alkyne substituent. *o*-Iodo aryl allyl ethers cyclize to benzofuran derivatives, for example, when treated with AIBN, aqueous H_3PO_2 and $NaHCO_3$ in ethanol.¹²⁵² Cyclization of an *o*-bromo-*N*-acyl aniline (a methacrylic acid derivative) with AIBN/ Bu_3SnH gave an indolone under the typical conditions used for cyclization of alkenes.¹²⁵³

Radical cyclization is compatible with the presence of other functional groups. Treatment of $XCH_2CON(R)-C(R^1)=CH_2$ derivatives ($X = Cl, Br, I$) with Ph_3SnH

of a phenylseleno ester with $\text{Bu}_3\text{SnH/AIBN}$ to form the acyl radical, which added to the first alkene unit.¹²⁷¹ The newly formed carbon radical added to the next alkene, and so on. Acyl radicals generated from Ts(R)NCOSePh derivatives cyclize to form lactams.¹²⁷²

Radical cyclization of iodo aldehydes or ketones, at the carbon of the carbonyl, is effectively an acyl addition reaction (**16-24**, **16-25**). This cyclization is often reversible, and there are many fewer examples can addition to an alkene or alkyne. In one example, a δ -iodo aldehyde was treated with BEt_3/O_2 to initiate formation of the radical, and in the presence of Bu_3SnH cyclization gave a cyclopentanol.¹²⁷³ The reaction of an aldehyde-alkene with AIBN, 0.5 PhSiH_3 and 0.1 Bu_3SnH generated a radical from the alkene, which cyclized at the aldehyde to give cyclopentanol derivatives.¹²⁷⁴ An aldehyde-*O*-methyloxime generated a radical adjacent to nitrogen under standard conditions, which cyclized at the carbonyl to give a cyclic α -hydroxy *N*-methoxyamine.¹²⁷⁵ Alternatively an α -bromoacetal-*O*-methyl oxime cyclized at the $\text{C}=\text{NOMe}$ unit under electrolytic conditions in the presence of cobaloxime.¹²⁷⁶

The attacking radical in radical cyclization reactions is not limited to a carbon, and a number of heterocycles can be prepared.¹²⁷⁷ Amidyl radical are known and give cyclization reactions.¹²⁷⁸ Aminyl radical cyclizations have been reported.¹²⁷⁹ *N*-Chloroamine-alkenes give an aminyl radical when treated with $\text{TiCl}_3\cdot\text{BF}_3$, and cyclization give a pyrrolidine derivative with a pendant chloromethyl group.¹²⁸⁰ *N*-(*S*-substituted) amines give similar results using AIBN/ Bu_3SnH .¹²⁸¹ Oxime-alkenes cyclize to imines when treated with PhSSPh and TEMPO (p. 274).¹²⁸² An oxygen radical can be generated under photochemical conditions, and they add to alkenes in a normal manner.¹²⁸³ Note that radical substitution occurs, and reaction of $\text{Ph}_3\text{SnH/AIBN}$ and an *O*-amidyl compound having a phosphonate ester elsewhere in the molecule gave cyclization to a tetrahydrofuran derivative.¹²⁸⁴

15-31 Conjugate Addition With Heteroatom Nucleophiles

Other nucleophiles add to conjugated systems to give Michael-type products. Aniline derivatives add to conjugated aldehydes in the presence of a catalytic amount of DBU (p. 1132).¹²⁸⁵ Amines add to conjugated esters in the presence of InCl_3 ,¹²⁸⁶ $\text{Bi}(\text{NO})_3$,¹²⁸⁷ $\text{Cu}(\text{OTf})_2$,¹²⁸⁸ $\text{CeCl}_3/\text{NaI}/\text{SiO}_2$,¹²⁸⁹ $\text{La}(\text{OTf})_3$,¹²⁹⁰ or $\text{Yb}(\text{OTf})_3$ at 3 kbar,¹²⁹¹ for example, to give β -amino esters. Palladium catalysts have been used as well.¹²⁹² Conjugate addition of amines has also been promoted by lithium perchlorate,¹²⁹³ and by clay.¹²⁹⁴ This reaction can be initiated photochemically¹²⁹⁵ or with microwave irradiation.¹²⁹⁶ Lithium amides add to conjugated esters to give the β -amino ester.¹²⁹⁷ An intramolecular addition of an amine unit to a conjugated ketone in the presence of a palladium catalyst, or photochemically, led to cyclic amines.¹²⁹⁸ Amines add to conjugated thio-lactams.¹²⁹⁹ Chiral catalysts lead to enantioselective reactions.¹³⁰⁰ Chiral imines add in a highly stereoselective manner.¹³⁰¹ Chiral additives, such as chiral Cinchona alkaloids¹³⁰² or chiral naphthol derivatives,¹³⁰³ have also been used. The nitrogen of carbamates add to conjugated ketones with a platinum,¹³⁰⁴ palladium,¹³⁰⁵ copper,¹³⁰⁶ or with a bis-(triflamide) catalyst.¹³⁰⁷ The amine moiety of a carbamate adds to conjugated

ketones with a polymer-supported acid catalyst,¹³⁰⁸ or with $\text{BF}_3 \cdot \text{OEt}_2$.¹³⁰⁹ Chiral catalysts have been used for the conjugated addition of carbamates.¹³¹⁰ The reaction of ammonium formate with 1,4-diphenylbut-2-en-1,4-dione, in PEG-200 and a palladium catalyst under microwave irradiation, gave 2,5-diphenylpyrrole.¹³¹¹

Lactams have been shown to add to conjugated esters in the presence of $\text{Si}(\text{OEt})_4$ and CsF .¹³¹² Phthalimide adds to alkylidene malononitriles via 1,4-addition with a palladium catalyst, and the resulting anion can be alkylated with an added allylic halide.¹³¹³ Alkylidene amido amides, $\text{C}=\text{C}(\text{NHAc})\text{CONHR}$, react with secondary amines in water to give the β -amino amido amide.¹³¹⁴ Amines also add in a conjugate manner to alkynyl phosphonate esters, $\text{C}\equiv\text{C}-\text{PO}(\text{OEt})_2$, using a CuI catalyst.¹³¹⁵ Hydroxylamines add to conjugated nitro compounds to give 2-nitro hydroxylamines.¹³¹⁶ *N,O*-Trimethylsilyl hydroxylamines add to conjugated esters, via nitrogen, using a copper catalyst.¹³¹⁷ Trimethylsilyl azide with acetic acid reacts with conjugated ketones to give the β -azido ketone.¹³¹⁸ Sodium azide adds to conjugated ketones in aqueous acetic acid and 20% PBu_3 .¹³¹⁹

Phosphines react similarly to amines under certain conditions. Conjugate addition of R_2PH and a nickel catalyst give conjugate addition to α,β -unsaturated nitriles.¹³²⁰

Alcohols add to conjugated ketones with a PMe_3 catalyst to give the β -alkoxy ketone.¹³²¹ The conjugate addition of peroxide anions (HOO^- and ROO^-) to α,β -unsaturated carbonyl compounds is discussed in **15-48**.

bis(Silanes) add to alkylidene malonate derivatives in the presence of a copper catalyst to give β -silyl malonates, $\text{RCH}(\text{SiR}_3)\text{CH}(\text{CO}_2\text{Me})_2$.¹³²² Alkylsilane units add using bis(trialkylsilyl)zinc reagents with a CuCN catalyst.¹³²³

Thiophenol and butyllithium (lithium phenylthiolate) adds to conjugated esters.¹³²⁴ Similar addition is observed with selenium compounds RSeLi .¹³²⁵

Thiols react with conjugated amides via 1,4-addition with the addition of 10% Hf(OTf)₄ or other lanthanide triflates¹³²⁶ or to conjugated ketones in ionic solvents.¹³²⁷ Thiophenol adds in a similar manner in the presence of Na₂CaP₂O₇¹³²⁸ or LiAl-poly₂a.¹³²⁹ Thioaryl moieties can be added in the presence of Yb¹³³⁰ or a catalytic amount of (DHQD)₂PYR (a dihydroquinidine, see **15-48**).¹³³¹ Thioalkyl units, such as BuS-, add to conjugated ketones using BuS-SnBu and In-I.¹³³² Addition of conjugated lactones is possible to produce β-arylthiolated lactones.¹³³³

α,β-Unsaturated sulfones undergo conjugate addition of a cyano group using Et₂AlCN.¹³³⁴ Trimethylsilyl cyanide (Me₃SiCN) adds a cyano group to α,β-unsaturated amines with a specialized aluminum salen-ytterbium catalyst.¹³³⁵

15-32 Acylation of Activated Double Bonds and of Triple Bonds

Hydro-acyl-addition

Under some conditions, acid derivatives add directly to activated double bonds. Acetic anhydride, magnesium metal, and Me₃SiCl reacts with conjugated esters to give a γ-keto ester.¹³³⁶ Similar reaction with vinyl phosphonate esters leads to a γ-keto phosphonate ester.¹³³⁷ Thioesters undergo conjugate addition to α,β-unsaturated ketones in the presence of SmI₂.¹³³⁸ Using DBU (1,8-diazabicyclo [5.4.0] undec-7-ene) (p. 1132) and a thioimidazolium salt, acyl silanes, Ar(C=O)SiMe₃, add in a similar manner.¹³³⁹ Under microwave irradiation, aldehydes add to conjugated ketones using DBU/Al₂O₃ and a thiazolium salt.¹³⁴⁰ The conjugate addition

of acyl zirconium complexes in the presence of $\text{BF}_3 \cdot \text{OEt}_2$ is catalyzed by palladium acetate.¹³⁴¹

An acyl group can be introduced into the 4 position of an α,β -unsaturated ketone by treatment with an organolithium compound and nickel carbonyl.¹³⁴² The product is a 1,4-diketone, **157**. The R group may be aryl or primary alkyl. The reaction can also be applied to alkynes (which need not be activated), in which case 2 mol add and the product is also a 1,4-diketone (e.g., $\text{R}'\text{C}\equiv\text{CH} \rightarrow \text{RCOCHR}'\text{CH}_2\text{COR}$).¹³⁴³ In a different procedure, α,β -unsaturated ketones and aldehydes are acylated by treatment at -110°C with $\text{R}_2(\text{CN})\text{CuLi}_2$ and CO. This method is successful for R = primary, secondary, and tertiary alkyl.¹³⁴⁴ For secondary and tertiary groups, $\text{R}(\text{CN})\text{CuLi}$ (which does not waste an R group) can be used instead.¹³⁴⁵

Another method involves treatment with an aldehyde and cyanide ion (see **16-52**) in a polar aprotic solvent (e.g., DMF or DMSO).¹³⁴⁶

This method has been applied to α,β -unsaturated ketones, esters, and nitriles to give the corresponding 1,4-diketones, γ -keto esters, and γ -keto nitriles, respectively (see also, **16-55**). The ion **158** is a synthon for the unavailable $\text{R}^\ominus\text{C}=\text{O}$ anion (see also, p. 634); it is a masked $\text{R}^\ominus\text{C}=\text{O}$ anion. Other masked carbanions that have been used in this reaction are the $\text{RC}^\ominus(\text{CN})\text{NR}$ ion,¹³⁴⁷ the $\text{EtSC}^\ominus\text{RSOEt}$ ion¹³⁴⁸ (see p. 634), the $\text{CH}_2=\text{C}^\ominus\text{OEt}$ ion,¹³⁴⁹ $\text{CH}_2=\text{C}(\text{OEt})\text{Cu}_2\text{Li}$,¹³⁵⁰ $\text{CH}_2=\text{CMe}(\text{SiMe}_3)$,⁷⁵⁰

and the $\text{RC}^{\ominus}(\text{OCHMeOEt})\text{CN}$ ion¹³⁵¹ (see p. 640). In the last case, best results are obtained when R is a vinylic group. Anions of 1,3-dithianes (**10-71**) do not give 1,4-addition to these substrates (except in the presence of HMPA, see **15-25**), but add 1,2 to the $\text{C}=\text{O}$ group instead (**16-38**).

In another procedure, acyl radicals derived from phenyl selenoesters ArCOSePh (by treatment of them with Bu_3SnH) add to α,β -unsaturated esters and nitriles to give γ -keto esters and γ -keto nitriles, respectively.¹³⁵²

OS VI, 866; VIII, 620.

15-33 Addition of Alcohols, Amines, Carboxylic Esters, Aldehydes, and so on.

Hydro-acyl-addition, and so on.

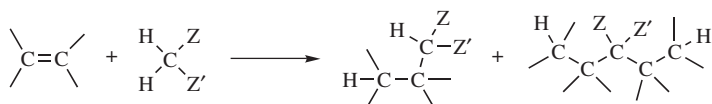

Formates, primary, and secondary alcohols, amines, ethers, alkyl halides, compounds of the type $\text{Z}-\text{CH}_2-\text{Z}'$, and a few other compounds add to double bonds in the presence of free-radical initiators.¹³⁵³ This is formally the addition of RH to a double bond, but the "R" is not just any carbon but one connected to an oxygen or a nitrogen, a halogen, or to two Z groups (defined as on p. 1007). Formates and formamides¹³⁵⁴ add similarly:

Alcohols, ethers, amines, and alkyl halides add as follows (shown for alcohols):

$\text{ZCH}_2\text{Z}'$ compounds react at the carbon bearing the active hydrogen:¹³⁵⁵

Similar additions have been successfully carried out with carboxylic acids, anhydrides,¹³⁵⁶ acyl halides, carboxylic esters, nitriles, and other types of compounds.¹³⁵⁷

Similar reactions have been carried out on acetylene.¹³⁵⁸ In an interesting variation, thiocarbonates add to alkynes in the presence of a palladium catalyst to give a β -phenylthio α,β -unsaturated ester.¹³⁵⁹ Aldehydes add to alkynes in the presence of a rhodium catalyst to give conjugated ketones.¹³⁶⁰ In a cyclic version of the addition of aldehydes, 4-pentalen was converted to cyclopentanone with a rhodium–complex catalyst.¹³⁶¹ An intramolecular acyl addition to an alkyne was reported using silyl ketones, acetic acid and a rhodium catalyst.¹³⁶² In the presence of a palladium catalyst, a tosylamide group added to an alkene unit to generate *N*-tosylpyrrolidine derivatives.¹³⁶³

15-34 Addition of Aldehydes

Alkyl-carbonyl-addition

In the presence of metal catalysts, such as rhodium compounds¹³⁶⁴ or $\text{Yb}(\text{OTf})_3$,¹³⁶⁵ aldehydes can add directly to alkenes to form ketones. The reaction of ω -alkenyl aldehydes with rhodium catalyst leads to cyclic ketones,¹³⁶⁶ with high enantioselectivity if chiral ligands are employed. Aldehydes also add to vinyl esters in the presence of hyponitrites and thioglycolates.¹³⁶⁷ The addition of aldehydes to activated double bonds, mediated by a catalytic amount of thiazolium salt in the presence of a

weak base, is called the *Stetter reaction*,¹³⁶⁸ An internal addition of an alkynyl aldehyde, catalyzed by a rhodium complex, led to a cyclopentenone derivative.¹³⁶⁹

A similar carbonyl addition with benzaldehyde derivatives having an ortho-allylic ether then led to a benzopyranone when treated with potassium hexamethyldisilazide.¹³⁷⁰

These reactions are not successful when the alkene contains electron-withdrawing groups, such as halo or carbonyl groups. A free-radical initiator is required,¹³⁷¹ usually peroxides or *UV* light. The mechanism is illustrated for aldehydes but is similar for the other compounds:

Polymers are often side products. Photochemical addition of aldehyde to conjugated C=C units can be efficient when a triplet sensitizer (p. 340), such as benzophenone is used.¹³⁷²

A variation that is more of an acyl addition (**16-25**) involves the reaction of an allylic alcohol with benzaldehyde. With a ruthenium catalyst and in an ionic liquid, the C=C unit reacts with the aldehyde, with concomitant oxidation of the allylic alcohol unit, to give a β -hydroxy ketone, $\text{PhCHO} + \text{C}=\text{C}-\text{CH}(\text{OH})\text{R} \rightarrow \text{PhCH}(\text{OH})-\text{CH}(\text{Me})\text{COR}$.¹³⁷³ In another variation, formate esters add to alkenes using a ruthenium catalyst to give an alkyl ester via a formylation process.¹³⁷⁴

The acid-catalyzed hydrocarboxylation of alkenes (the *Koch reaction*) can be performed in a number of ways.¹³⁷⁵ In one method, the alkene is treated with carbon monoxide and water at 100–350°C and 500–1000-atm pressure with a mineral acid catalyst. However, the reaction can also be performed under milder conditions. If the alkene is first treated with CO and catalyst and then water added, the reaction can be accomplished at 0–50°C and 1–100 atm. If formic acid is used as the source of both the CO and the water, the reaction can be carried out at room temperature and atmospheric pressure.¹³⁷⁶ The formic acid procedure is called the *Koch–Haaf reaction* (the Koch–Haaf reaction can also be applied to alcohols, see 10-77). Nearly all alkenes can be hydrocarboxylated by one or more of these procedures. However, conjugated dienes are polymerized instead. Hydrocarboxylation can also be accomplished under mild conditions (160°C and 50 atm) by the use of nickel carbonyl as catalyst. Acid catalysts are used along with the nickel carbonyl, but basic catalysts can also be employed.¹³⁷⁷ Other metallic salts and complexes can be used, sometimes with variations in the reaction procedure, including palladium,¹³⁷⁸ platinum,¹³⁷⁹ and rhodium¹³⁸⁰ catalysts. The Ni(CO)₄-catalyzed oxidative carbonylation with CO and water as a nucleophile is often called *Reppe carbonylation*.¹³⁸¹ The toxic nature of nickel

tetracarbonyl has led to development of other catalysts, including Co, Rh, Ir, Pd, and Pt, and Mo compounds.¹³⁸² This reaction converts alkenes, alkynes and dienes and is tolerant of a wide variety of functional groups. When the additive is alcohol or acid, saturated or unsaturated acids, esters, or anhydrides are produced (see **15-36**). The transition-metal-catalyzed carbonylation has been done enantioselectively, with moderate-to-high optical yields, by the use of an optically active palladium complex catalyst.¹³⁸³ Dienes react with $\text{Cp}_2\text{TiCl}_2/\text{RMgCl}$ and then with Me_2NCOCI to give amides.¹³⁸⁴ In the presence of formic acid, CO, and palladium acids can similarly be formed.¹³⁸⁵ Alkenes also react with $\text{Fe}(\text{CO})_5$ and CO to give carboxylic acids.¹³⁸⁶ Electrochemical carboxylation procedures have been developed, including the conversion of alkenes to 1,4-butane-dicarboxylic acids.¹³⁸⁷

When applied to triple bonds, hydrocarboxylation gives α,β -unsaturated acids under very mild conditions. Triple bonds give unsaturated acids and saturated dicarboxylic acids when treated with carbon dioxide and an electrically reduced nickel complex catalyst.¹³⁸⁸ Alkynes also react with $\text{NaHFe}(\text{CO})_4$, followed by $\text{CuCl}_2 \bullet 2\text{H}_2\text{O}$, to give alkenyl acid derivatives.¹³⁸⁹ A related reaction with CO and palladium catalysts in the presence of SnCl_2 also leads to conjugated acid derivatives.¹³⁹⁰ Terminal alkynes react with CO_2 and $\text{Ni}(\text{cod})_2$, and subsequent treatment with DBU (p. 1132) gives the α,β -unsaturated carboxylic acid.¹³⁹¹

When acid catalysts are employed, in the absence of nickel carbonyl, the mechanism¹³⁹² involves initial attack by a proton, followed by attack of the resulting carbocation on carbon monoxide to give an acyl cation, which, with water, gives the product, **159**. Markovnikov's rule is followed, and carbon skeleton rearrangements and double-bond isomerizations (prior to attack by CO) are frequent.

For the transition metal catalyzed reactions, the nickel carbonyl reaction has been well studied and the addition is syn for both alkenes and alkynes.¹³⁹³ The following is the accepted mechanism:⁷⁸⁵

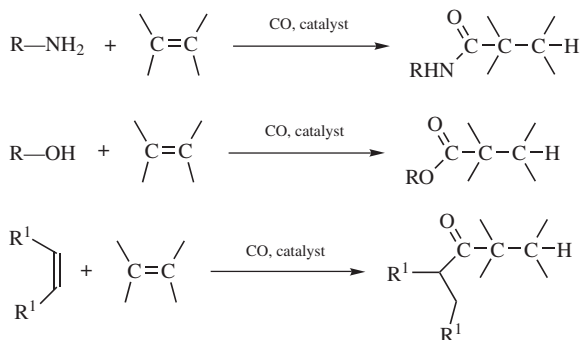

Step 3 is an electrophilic substitution. The principal step of the mechanism, step 4, is a rearrangement.

An indirect method for hydrocarboxylation involves the reaction of an alkene with a borate, $(\text{RO})_2\text{BH}$ and a rhodium catalysts. Subsequent reaction with LiCHCl_2 and then NaClO_2 gives the Markovnikov carboxylic acid $(\text{RC}=\text{C} \rightarrow \text{RC}(\text{COOH})\text{CH}_3$).¹³⁹⁴ When a chiral ligand is used, the reaction proceeds with good enantioselectivity.

15-36 Carbonylation, Alkoxy-carbonylation and Aminocarbonylation of Double and Triple Bonds

Alkyl, Alkoxy or Amino-carbonyl-addition

¹³⁹⁴Chen, A.; Ren, L.; Crudden, C.M. *J. Org. Chem.* **1999**, *64*, 9704.

In the presence of certain metal catalysts, alkenes and alkynes can be carbonylated or converted to amides or esters.¹³⁹⁵ There are several variations. The reaction of an alkyl iodide and a conjugated ester with CO, (Me₃Si)₃SiH and AIBN (p. 935) in supercritical CO₂ (p. 414) gave a γ -keto ester.¹³⁹⁶ Terminal alkynes react with CO and methanol, and in the presence of CuCl₂ and PdCl₂ the product is a β -chloro- α - β -unsaturated methyl ester.¹³⁹⁷ Conjugated dienes react with thiophenol, CO and palladium(II) acetate to give the β,γ -unsaturated thioester.¹³⁹⁸ Allene reacts with CO, methanol and a ruthenium catalyst to give methacrylic acid.¹³⁹⁹ 5-Iodo-1-pentene reacted with 40 atm of CO in butanol to give a cyclopentanone with a pendant ester (–CH₂CO₂Bu).¹⁴⁰⁰ Alkynes react with thiophenol and CO with a palladium¹⁴⁰¹ or platinum¹⁴⁰² catalyst to give a conjugated thioester. Terminal alkynes react with CO and methanol, using a combination of a palladium (II) halide and a copper (II) halide, to give a conjugated diester, MeO₂C–C=C–CO₂Me.¹⁴⁰³ A similar reaction with alkenes using a combination of a palladium and a molybdenum catalyst led to a saturated diester, MeO₂C–C–C–CO₂Me.¹⁴⁰⁴ Alkenes were converted to the dimethyl ester of 1,4-butanedioic acid derivatives with CO/O₂ and a combination of PdCl₂ and CuCl catalysts.¹⁴⁰⁵ Note that alkenes are converted to primarily the anti-Markovnikov ester upon treatment with arylmethyl formate esters (ArCH₂OCHO) and a ruthenium catalyst.¹⁴⁰⁶

A bicyclic ketone was generated when 1,2-diphenylethyne was heated with CO, methanol and a dirhodium catalyst.¹⁴⁰⁷ 2-Iodostyrene reacted at 100°C with CO and a palladium catalyst to give the bicyclic ketone 1-indanone.¹⁴⁰⁸ Another variation reacted a conjugated allene–alkene with 5 atm of CO and a rhodium catalyst to give a bicyclic ketone.¹⁴⁰⁹ An intermolecular version of this reaction is known

using a cobalt catalyst, giving a cyclopentenone¹⁴¹⁰ in a reaction related to the Pauson–Khand reaction (see below). The reaction of a conjugated diene having a distal alkene unit and CO with a rhodium catalyst led to a bicyclic conjugated ketone.¹⁴¹¹ When a Stille coupling (**12-15**) is done in a CO atmosphere, conjugated ketones of the type C=C–CO–C=C are formed,¹⁴¹² suitable for a Nazarov cyclization (**15-20**). Alkynes were converted to cyclobutenones using Fe₃(CO)₁₂ to form the initial complex, followed by reaction with copper(II) chloride.¹⁴¹³ An interesting variation treated cyclohexene with 5 equivalents of Oxone[®] and a RuCl₃ catalyst to give 2-hydroxycyclohexanone.¹⁴¹⁴

The reaction of dienes, diynes, or en-yne with transition metals¹⁴¹⁵ (usually cobalt)¹⁴¹⁶ forms organometallic coordination complexes. In the presence of carbon monoxide, the metal complexes derived primarily from enynes (alkene–alkynes) form cyclopentenone derivatives in what is known as the *Pauson–Khand reaction*.¹⁴¹⁷ The reaction involves (1) formation of a hexacarbonyldicobalt–alkyne complex and (2) decomposition of the complex in the presence of an alkene.¹⁴¹⁸ A typical example is formation of **160**.¹⁴¹⁹ Cyclopentenones can be prepared by an intermolecular reaction of a vinyl silane and an alkyne using CO and a ruthenium catalyst.¹⁴²⁰ Carbonylation of an alkene–diene using a rhodium catalyst leads to cyclization to an α -vinyl cyclopentanone.¹⁴²¹ An yne–diene can also be used for the Pauson–Khand reaction.¹⁴²²

Rhodium,¹⁴²³ titanium,¹⁴²⁴ and tungsten¹⁴²⁵ complexes have also been used for this reaction. The reaction can be promoted photochemically¹⁴²⁶ and the rate is enhanced by the presence of primary amines.¹⁴²⁷ Coordinating ligands also accelerate the reaction,¹⁴²⁸ polymer-supported promoters have been developed¹⁴²⁹ and there are many possible variations in reaction conditions.¹⁴³⁰ The Pauson–Khand reaction has been done under heterogeneous reaction conditions,¹⁴³¹ and with cobalt nanoparticles.¹⁴³² A dendritic cobalt catalyst has been used.¹⁴³³ Ultrasound promoted¹⁴³⁴ and microwave promoted¹⁴³⁵ reactions have been developed. Polycyclic compounds (tricyclic and higher) are prepared in a relatively straightforward manner using this reaction.¹⁴³⁶ Asymmetric Pauson–Khand reactions are known.¹⁴³⁷

The Pauson–Khand reaction is compatible with other groups or heteroatoms elsewhere in the molecule. These include ethers and aryl halides,¹⁴³⁸ esters,¹⁴³⁹

amides,¹⁴⁴⁰ alcohols,¹⁴⁴¹ diols,¹⁴⁴² and an indole unit.¹⁴⁴³ A silicon-tethered Pauson–Khand reaction is known.¹⁴⁴⁴ Allenes are reaction partners in the Pauson–Khand reaction.¹⁴⁴⁵ This type of reaction can be extended to form six-membered rings using a ruthenium catalyst.¹⁴⁴⁶ A double-Pauson–Khand process was reported.¹⁴⁴⁷ In some cases, an aldehyde can serve as the source of the carbonyl for carbonylation.¹⁴⁴⁸

The accepted mechanism was proposed by Magnus,¹⁴⁴⁹ shown for the formation of **161**,¹⁴⁵⁰ and supported by Krafft's work.¹⁴⁵¹ It has been shown that CO is lost from the Pauson–Khand complex prior to alkene coordination and insertion.¹⁴⁵² Calculations concluded that the LUMO of the coordinated alkene plays a crucial role in alkene reactivity by determining the degree of back-donation in the complex.¹⁴⁵³

Other carbonylation methods are available. Carbonylation occurs with conjugated ketones to give 1,4-diketones, using phenylboronic acid (**13-12**), CO and a rhodium catalyst.¹⁴⁵⁴ A non-carbonylation route treated a conjugated diene with an

excess of *tert*-butyllithium and quenching with carbon dioxide led to a cyclopentadienone.¹⁴⁵⁵ When quenched with CO rather than CO₂, a nonconjugated cyclopentenone was formed.¹⁴⁵⁶ It is noted that a carbonylation reaction with CO, a diyne and an iridium catalyst¹⁴⁵⁷ or a cobalt catalyst¹⁴⁵⁸ provided similar molecules.

The reaction of a secondary amine, CO, a terminal alkyne and *t*-BuMe₂SiH with a rhodium catalyst led to a conjugated amide bearing the silyl group of the C=C unit.¹⁴⁵⁹ Reaction of a molecule containing an amine and an alkene unit was carbonylated with CO in the presence of a palladium catalyst to give a lactam.¹⁴⁶⁰ A similar reaction with a molecule containing an amine and an alkyne also generated a lactam, in the presence of CO and a rhodium catalyst.¹⁴⁶¹ An intramolecular carbonylation reaction of a conjugated imine, with CO, ethylene and a ruthenium catalyst, led to a highly substituted β,γ-unsaturated lactam.¹⁴⁶²

With any method, if the alkene contains a functional group, such as OH, NH₂, or CONH₂, the corresponding lactone (**16-63**),¹⁴⁶³ lactam (**16-74**), or cyclic imide may be the product.¹⁴⁶⁴ Titanium,¹⁴⁶⁵ palladium,¹⁴⁶⁶ ruthenium,¹⁴⁶⁷ and rhodium¹⁴⁶⁸ catalysts have been used to generate lactones. Allenic alcohols are converted to butenolides with 10 atm of CO and a ruthenium catalyst.¹⁴⁶⁹ Larger ring conjugated lactones can also be formed by this route using the appropriate allenic alcohol.¹⁴⁷⁰ Propargylic alcohols lead to β-lactones.¹⁴⁷¹ Allenic tosyl-amides are converted to *N*-tosyl α,β-unsaturated pyrrolidinones using 20 atm of CO and a ruthenium catalyst.¹⁴⁷² Conjugated imines are converted to similar products with CO, ethylene and a ruthenium catalyst.¹⁴⁷³ Propargyl alcohols are converted to

butenolides with CO/H₂O and a rhodium catalyst.¹⁴⁷⁴ Propargyl alcohols generate lactones when treated with a chromium pentacarbonyl carbene complex.¹⁴⁷⁵ Amines add to allenes, in the presence of CO and a palladium catalyst, to form conjugated amides.¹⁴⁷⁶

15-37 Hydroformylation

Hydro-formyl-addition

Alkenes can be hydroformylated¹⁴⁷⁷ by treatment with carbon monoxide and hydrogen over a catalyst. The most common catalysts are cobalt carbonyls (see below for a description of the mechanism) and rhodium complexes,¹⁴⁷⁸ but other transition metal compounds have also been used. Cobalt catalysts are less active than the rhodium type, and catalysts of other metals are generally less active.¹⁴⁷⁹ Commercially, this is called the *oxo process*, but it can be carried out in the laboratory in an ordinary hydrogenation apparatus. The order of reactivity is straight-chain terminal alkenes > straight-chain internal alkenes > branched-chain alkenes. With terminal alkenes, for example, the aldehyde unit is formed on both the primary and secondary carbon, but proper choice of catalyst and additive leads to selectivity for the secondary product¹⁴⁸⁰ or primary

product.¹⁴⁸¹ Good yields for hydroformylation have been reported using rhodium catalysts in the presence of certain other additives.¹⁴⁸² Among the side reactions are the aldol reaction (**16-34**), acetal formation, the Tishchenko reaction (**19-82**), and polymerization. In one case using a rhodium catalyst, 2-octene gave nonanal, presumably via a η^3 -allyl complex (p. 116).¹⁴⁸³ Conjugated dienes give dialdehydes when rhodium catalysts are used¹⁴⁸⁴ but saturated mono-aldehydes (the second double bond is reduced) with cobalt carbonyls. Both 1,4- and 1,5-dienes may give cyclic ketones.¹⁴⁸⁵ Hydroformylation of triple bonds proceeds very slowly, and few examples have been reported.¹⁴⁸⁶ However, in the presence of a rhodium catalyst, the triple bond of a conjugated enyne is formylated.¹⁴⁸⁷ Many functional groups such as OH, CHO, COOR,¹⁴⁸⁸ CN, can be present in the molecule, although halogens usually interfere. Stereoselective syn addition has been reported,¹⁴⁸⁹ and also stereoselective anti addition.¹⁴⁹⁰ Asymmetric hydroformylation has been accomplished with a chiral catalyst,¹⁴⁹¹ and in the presence of chiral additives.¹⁴⁹² Cyclization to prolinol derivatives has been reported with allylic amines.¹⁴⁹³

When dicobalt octacarbonyl, $[\text{Co}(\text{CO})_4]_2$, is the catalyst, the species that actually adds to the double bond is tricarbonylhydrocobalt, $\text{HCo}(\text{CO})_3$.¹⁴⁹⁴ Carbonylation $\text{RCo}(\text{CO})_3 + \text{CO} \rightarrow \text{RCo}(\text{CO})_4$ takes place, followed by a rearrangement and a

reduction of the C—Co bond, similar to steps 4 and 5 of the nickel carbonyl mechanism shown in **15-35**. The reducing agent in the reduction step is tetracarbonylhydrocobalt, $\text{HCo}(\text{CO})_4$,¹⁴⁹⁵ or, under some conditions, H_2 .¹⁴⁹⁶ When $\text{HCo}(\text{CO})_4$ was the agent used to hydroformylate styrene, the observation of CIDNP indicated that the mechanism is different, and involves free radicals.¹⁴⁹⁷ Alcohols can be obtained by allowing the reduction to continue after all the carbon monoxide is used up. It has been shown¹⁴⁹⁸ that the formation of alcohols is a second step, occurring after the formation of aldehydes, and that $\text{HCo}(\text{CO})_3$ is the reducing agent.

OS VI, 338.

15-38 Addition of HCN

Hydro-cyano-addition

Ordinary alkenes do not react with HCN, but polyhalo alkenes and alkenes of the form $\text{C}=\text{C}-\text{Z}$ add HCN to give nitriles.¹⁴⁹⁹ The reaction is therefore a nucleophilic addition and is base catalyzed. When Z is COR or, more especially, CHO, 1,2-addition (**16-53**) is an important competing reaction and may be the only reaction. Triple bonds react very well when catalyzed by an aqueous solution of CuCl , NH_4Cl , and HCl or by Ni or Pd compounds.¹⁵⁰⁰ The HCN can be generated *in situ* from acetone cyanohydrin (see **16-52**), avoiding the use of the poisonous HCN.¹⁵⁰¹ One or 2 equivalents of HCN can be added to a triple bond, since the initial product is a Michael-type substrate. Acrylonitrile is commercially prepared this way, by the addition of HCN to acetylene. Alkylaluminum cyanides, for example, Et_2AlCN , or mixtures of HCN and trialkylalanes R_3Al are especially good reagents for conjugate addition of HCN¹⁵⁰² to α,β -unsaturated ketones and α,β -unsaturated acyl halides. Hydrogen cyanide can be added to ordinary alkenes in the presence of dicobalt octacarbonyl¹⁵⁰³ or certain other

transition-metal compounds.¹⁵⁰⁴ An indirect method for the addition of HCN to ordinary alkenes uses an isocyanide (RNC) and Schwartz's reagent (see **15-17**); this method gives anti-Markovnikov addition.¹⁵⁰⁵ *tert*-Butyl isocyanide and TiCl₄ have been used to add HCN to C=C–Z alkenes.¹⁵⁰⁶ Pretreatment with NaI/Me₃SiCl followed by CuCN converts alkynes to vinyl nitriles.¹⁵⁰⁷

When an alkene is treated with Me₃SiCN and AgClO₄, followed by aq. NaHCO₃, the product is the isonitrile (RNC) formed with Markovnikov selectivity.¹⁵⁰⁸ An alternative reagent is the cyanohydrin of acetone, which adds to alkenes to give a nitrile in the presence of a nickel complex.¹⁵⁰⁹

Most double bonds are easily halogenated¹⁵¹⁰ with bromine, chlorine, or inter-halogen compounds.¹⁵¹¹ Substitution can compete with addition in some cases.¹⁵¹² Iodination has also been accomplished, but the reaction is slower.¹⁵¹³ Under free-radical conditions, iodination proceeds more easily.¹⁵¹⁴ However, *vic*-diiodides are generally unstable and tend to revert to iodine and the alkene.

The mechanism is usually electrophilic (see p. 1002), involving formation of an halonium ion (**162**),¹⁵¹⁵ followed by nucleophilic opening to give the *vic*-dihalide. Nucleophilic attack occurs with selectivity for the less substituted carbon with unsymmetrical alkenes. When free-radical initiators (or UV light) are present, addition can occur by a free-radical mechanism.¹⁵¹⁶ Once Br• or Cl• radicals are formed, however, substitution may compete (**14-1** and **14-3**). This is especially important when the alkene has allylic hydrogens. Under free-radical conditions (UV light) bromine or chlorine adds to the benzene ring to give, respectively, hexabromo- and hexachlorocyclohexane. These are mixtures of stereoisomers (see p. 187).¹⁵¹⁷

Under ordinary conditions fluorine itself is too reactive to give simple addition; it attacks other bonds and mixtures are obtained.¹⁵¹⁸ However, F₂ has been successfully added to certain double bonds in an inert solvent at low temperatures (−78°C), usually by diluting the F₂ gas with Ar or N₂.¹⁵¹⁹ Addition of fluorine has also been accomplished with other reagents (e.g., *p*-Tol-IF₂/Et₃N•5 HF),¹⁵²⁰ and a mixture of PbO₂ and SF₄.¹⁵²¹

The reaction with bromine is very rapid and is easily carried out at room temperature,¹⁵²² although the reaction is reversible under some conditions.¹⁵²³ In the case of bromine, an alkene•Br₂ complex has been detected in at least one case.¹⁵²⁴ Bromine is often used as a test, qualitative or quantitative, for unsaturation.¹⁵²⁵ The vast majority of double bonds can be successfully brominated. Even when aldehyde, ketone, amine, and so on functions are present in the molecule, they do not interfere, since the reaction with double bonds is faster. Bromination has been carried out in an ionic liquid.¹⁵²⁶

Several other reagents add Cl₂ to double bonds, among them Me₃SiCl⁻MnO₂,¹⁵²⁷ NaClO₂/Mn(acac)₂/moist Al₂O₃,¹⁵²⁸ BnNEt₃MnO₄/Me₃SiCl,¹⁵²⁹ and KMnO₄-oxalyl chloride.¹⁵³⁰ A convenient reagent for the addition of Br₂ to a double bond on a small scale is the commercially available pyridinium bromide perbromide C₅H₅NH⁺Br₃⁻.¹⁵³¹ Potassium bromide with ceric ammonium nitrate, in water/dichloromethane, gives the dibromide.¹⁵³² A combination of KBr and Selectfluor also give the dibromide.¹⁵³³ A combination of CuBr₂ in aq. THF and a chiral ligand led to the dibromide with good enantioselectivity.¹⁵³⁴ A mixture of (decyl)Me₃NMnO₄ and Me₃SiBr is also an effective reagent.¹⁵³⁵ Either Br₂ or Cl₂ can also be added with CuBr₂ or CuCl₂ in the presence of a compound, such as acetonitrile, methanol, or triphenylphosphine.¹⁵³⁶

Mixed halogenations have also been achieved, and the order of activity for some of the reagents is $\text{BrCl} > \text{ICl}^{1537} > \text{Br}_2 > \text{IBr} > \text{I}_2$.¹⁵³⁸ Mixtures of Br_2 and Cl_2 have been used to give bromochlorination,¹⁵³⁹ as has tetrabutylammonium dichlorobromate, $\text{Bu}_4\text{NBrCl}_2$,¹⁵⁴⁰ iodochlorination has been achieved with KICl_2 ,¹⁵⁴¹ CuCl_2 , and either I_2 , HI , or CdI_2 ; iodofluorination¹⁵⁴² with mixtures of AgF and I_2 ,¹⁵⁴³ and mixtures of *N*-bromo amides in anhydrous HF give bromofluorination.¹⁵⁴⁴ Bromo-, iodo-, and chlorofluorination have also been achieved by treatment of the substrate with a solution of Br_2 , I_2 , or an *N*-halo amide in polyhydrogen fluoride-pyridine,¹⁵⁴⁵ while addition of I along with Br , Cl , or F has been accomplished with the reagent bis(pyridine)iodo(I) tetrafluoroborate $\text{I}(\text{Py})_2\text{BF}_4$ and Br^- , Cl^- , or F^- , respectively.¹⁵⁴⁶ This reaction (which is also successful for triple bonds¹⁵⁴⁷) can be extended to addition of I and other nucleophiles (e.g., NCO , OH , OAc , and NO_2).¹⁵⁴⁷ Cyclohexene is converted to *trans*-2-fluoroiodocyclohexane under electrolytic conditions using $\text{Et}_4\text{NI}-\text{Et}_3\text{N}\bullet\text{HF}$ in the reaction medium.¹⁵⁴⁸

Conjugated systems give both 1,2- and 1,4-addition.¹⁵¹⁸ Triple bonds add bromine, although generally more slowly than double bonds (see p. 1015). Molecules that contain both double and triple bonds are preferentially attacked at the double bond. Addition of 2 equivalents of bromine to triple bonds gives tetrabromo products. There is evidence that the addition of the first mole of bromine to a triple bond may take place by a nucleophilic mechanism.¹⁵⁴⁹ Molecular diiodine on Al_2O_3 adds to triple bonds to give good yields of 1,2-diiodoalkenes.¹⁵⁵⁰ Interestingly, 1,1-diiodo alkenes are prepared from an alkynyltin compound, via initial treatment with $\text{Cp}_2\text{Zr}(\text{H})\text{Cl}$, and then 2.15 equivalents of iodine.¹⁵⁵¹ A mixture of

15-40 Addition of Hypohalous Acids and Hypohalites (Addition of Halogen, Oxygen)

Hydroxy-chloro-addition, and so on.¹⁵⁵⁴

Alkoxy-chloro-addition, and so on.

Hypohalous acids (HOCl, HOBr, and HOI) can be added to alkenes¹⁵⁵⁵ to produce halohydrins.¹⁵⁵⁶ Both HOBr and HOCl are often generated *in situ* by the reaction between water and Br₂ or Cl₂, respectively. HOI, generated from I₂ and H₂O, also adds to double bonds, if the reaction is carried out in tetramethylene sulfone-CHCl₃¹⁵⁵⁷ or if an oxidizing agent, such as HIO₃ is present.¹⁵⁵⁸ Iodine and cerium sulfate in aqueous acetonitrile generates iodohydrins,¹⁵⁵⁹ as does iodine and ammonium acetate in acetic acid,¹⁵⁶⁰ or NaIO₄ with sodium bisulfite.¹⁵⁶¹ The HOBr can also be conveniently added by the use of a reagent consisting of an *N*-bromo amide

(e.g., NBS or *N*-bromoacetamide) and a small amount of water in a solvent, such as DMSO or dioxane.¹⁵⁶² *N*-Iodosuccinimide (NIS) in aqueous dimethoxyethane leads to the iodohydrin.¹⁵⁶³ An especially powerful reagent for HOCl addition is *tert*-butyl hydroperoxide (or di-*tert*-butyl peroxide) along with TiCl₄. This reaction is generally complete within 15 min at -78°C .¹⁵⁶⁴ Chlorohydrins can be conveniently prepared by treatment of the alkene with Chloramine T (TsNCl⁻ Na⁺)¹⁵⁶⁵ in acetone–water.¹⁵⁶⁶ The compound HOI can be added by treatment of alkenes with periodic acid and NaHSO₃.¹⁵⁶⁷ The reaction of an alkene with polymeric (SnO)_{*n*}, and then HCl with Me₃SiOOSiMe₃ leads to the chlorohydrin.¹⁵⁶⁸ Hypervalent iodine compounds react with an alkene and iodine in aqueous media to give the iodohydrin.¹⁵⁶⁹

The compound HOF has also been added, but this reagent is difficult to prepare in a pure state and *explosions have occurred*.¹⁵⁷⁰

The mechanism of HOX addition is electrophilic, with initial attack by the positive halogen end of the HOX dipole. Following Markovnikov's rule, the positive halogen goes to the side of the double bond that has more hydrogens (forming a more stable carbocation). This carbocation (or bromonium or iodonium ion in the absence of an aqueous solvent) reacts with ⁻OH or H₂O to give the product. If the substrate is treated with Br₂ or Cl₂ (or another source of positive halogen such as NBS) in an alcohol or a carboxylic acid solvent, it is possible to obtain,

directly $\text{X}-\underset{\text{|}}{\overset{\text{|}}{\text{C}}}-\underset{\text{|}}{\overset{\text{|}}{\text{C}}}-\text{OR}$ or $\text{X}-\underset{\text{|}}{\overset{\text{|}}{\text{C}}}-\underset{\text{|}}{\overset{\text{|}}{\text{C}}}-\text{OCOR}$, respectively (see also, **15-48**).¹⁵⁷¹

Even the weak nucleophile CF₃SO₂O⁻ can participate in the second step: The addition of Cl₂ or Br₂ to alkenes in the presence of this ion resulted in the formation of some β-haloalkyl triflates.¹⁵⁷² There is evidence that the mechanism with Cl₂ and H₂O is different from that with HOCl.¹⁵⁷³ HOCl and HOBr can be added to triple bonds to give dihalo carbonyl compounds –CX₂–CO–.

Alcohols and halogens react with alkenes to form halo ethers. When a homoallylic alcohol is treated with bromine, cyclization occurs to give a 3-bromotetrahydrofuran derivative.¹⁵⁷⁴ *tert*-Butyl hypochlorite (Me₃COCl), hypobromite, and hypoiodite¹⁵⁷⁵ add to double bonds to give halogenated *tert*-butyl ethers, X-C-C-OCMe₃. This is a convenient method for the preparation of tertiary ethers. Iodine and ethanol convert some alkenes to iodo-ethers.¹⁵⁷⁶ Iodine, alcohol and a Ce(OTf)₂ catalyst also generates the iodo-ether.¹⁵⁷⁷ When Me₃COCl or Me₃COBr is added to alkenes in the presence of excess ROH, the ether produced

is $\begin{array}{c} | \quad | \\ \text{X}-\text{C}-\text{C}-\text{OR} \\ | \quad | \end{array}$.¹⁵⁷⁸ Vinylic ethers give β -halo acetals.¹⁵⁷⁹ A mixture of Cl₂ and

SO₃ at -78°C converts alkenes to 2-chloro chlorosulfates ClCH₂CHROSO₂Cl, which are stable compounds.¹⁵⁸⁰ Chlorine acetate [solutions of which are prepared by treating Cl₂ with Hg(OAc)₂ in an appropriate solvent] adds to alkenes to give acetoxy chlorides.¹⁵⁸¹ Acetoxy fluorides have been obtained by treatment of alkenes with CH₃COOF.¹⁵⁸²

For a method of iodoacetyl addition, see **15-48**.

An oxidative variation of this reaction treats a vinyl chloride with NaOCl and acetic acid, generating an α -chloro ketone.¹⁵⁸³

halolactonization.¹⁵⁸⁴

The most common version of this reaction is known as *iodolactonization*,¹⁵⁸⁵ and a typical example is the conversion of **163** to **164**.¹⁵⁸⁶ Bromo lactones and, to a lesser extent, chloro lactones have also been prepared. In general, addition of the halogen to an alkenyl acid, as shown, leads to the halo-lactone. Other reagents include I^+ (collidine) $_2\text{PF}_6^-$,¹⁵⁸⁷ KI/sodium persulfate.¹⁵⁸⁸ Thallium reagents, along with the halogen, have also been used.¹⁵⁸⁹ When done in the presence of a chiral titanium reagent, I_2 , and CuO, lactones are formed with good enantioselectivity.¹⁵⁹⁰ ICl has been used, with formation of a quaternary center at the oxygen-bearing carbon of the lactone.¹⁵⁹¹

In the case of γ,δ -unsaturated acids, 5-membered rings (γ -lactones) are predominantly formed (as shown above; note that Markovnikov's rule is followed), but 6-membered and even 4-membered lactones have also been made by this procedure. There is a gem-dimethyl effect that favors formation of 7–11-membered ring lactones by this procedure.¹⁵⁹²

Formation of halo-lactams (**15-43**) by a similar procedure is difficult, but the problems have been overcome. Formation of a triflate followed by treatment with iodine leads to the iodo-lactam, **165**.¹⁵⁹³

A related cyclization of *N*-sulfonyl-amino-alkenes and NBS gave the bromo-lactam,¹⁵⁹⁴ and a dichloro-*N,N*-bis(allylamide) was converted to a dichloro-lactam with FeCl₂.¹⁵⁹⁵ It is noted that lactone formation is possible from unsaturated amides. The reaction of 3-methyl *N,N*-dimethylpent-4-ene amide with iodine in aqueous acetonitrile, for example, gave iodolactone **166**.¹⁵⁹⁶

OS IX, 516.

15-42 Addition of Sulfur Compounds (Addition of Halogen, Sulfur)

Alkylsulfonyl-chloro-addition, and so on.¹⁵⁹⁷

Sulfonyl halides add to double bonds, to give β -halo sulfones, in the presence of free-radical initiators or UV light. A particularly good catalyst is cuprous chloride.¹⁵⁹⁸ A combination of the anion ArSO₂Na, NaI, and ceric ammonium nitrate converts alkenes to vinyl sulfones.¹⁵⁹⁹ Triple bonds behave similarly, to give β -halo- α,β -unsaturated sulfones.¹⁶⁰⁰ In a similar reaction, sulfonyl chlorides, RSO₂Cl, give β -halo thioethers.¹⁶⁰¹ The latter may be free-radical or electrophilic additions, depending on conditions. The addition of MeS and Cl has also been accomplished by treating the alkene with Me₃SiCl and Me₂SO.¹⁶⁰² The use of Me₃SiBr and Me₂SO does not give this result; dibromides (**15-39**) are formed instead. β -Iodo

15-44 Addition of NOX and NO₂X (Addition of Halogen, Nitrogen)

Nitroso-chloro-addition

There are three possible products when NOCl is added to alkenes, a β-halo nitroso compound, an oxime, or a β-halo nitro compound.¹⁶¹⁵ The initial product is always the β-halo nitroso compound,¹⁶¹⁶ but these are stable only if the carbon bearing the nitrogen has no hydrogen. If it has, the nitroso compound tautomerizes to the oxime, $\text{H}-\text{C}-\text{N}=\text{O} \rightarrow \text{C}=\text{N}-\text{OH}$. With some alkenes, the initial β-halo nitroso compound is oxidized by the NOCl to a β-halo nitro compound.¹⁶¹⁷ Many functional groups can be present without interference (e.g., COOH, COOR, CN, OR). The mechanism in most cases is probably simple electrophilic addition, and the addition is usually anti, although syn addition has been reported in some cases.¹⁶¹⁸ Markovnikov's rule is followed, the positive NO going to the carbon that has more hydrogens.

Nitryl chloride NO₂Cl also adds to alkenes, to give β-halo nitro compounds, but this is a free-radical process. The NO₂ goes to the less-substituted carbon.¹⁶¹⁹ Nitryl chloride also adds to triple bonds to give the expected 1-nitro-2-chloro alkenes.¹⁶²⁰ The compound FNO₂ can be added to alkenes¹⁶²¹ by treatment with HF in HNO₃¹⁶²² or by addition of the alkene to a solution of nitronium tetrafluoroborate (NO₂⁺ BF₄⁻) (see 11-2) in 70% polyhydrogen fluoride-pyridine solution¹⁶²³ (see also 15-37).

The addition of iodine azide to double bonds gives β -iodo azides.¹⁶²⁴ The reagent can be prepared *in situ* from KI–NaN₃ in the presence of Oxone[®]-wet alumina.¹⁶²⁵ The addition is stereospecific and anti, suggesting that the mechanism involves a cyclic iodonium ion intermediate.¹⁶²⁶ The reaction has been performed on many double-bond compounds, including allenes¹⁶²⁷ and α,β -unsaturated ketones. Similar reactions can be performed with BrN₃¹⁶²⁸ and ClN₃. 1,4-Addition has been found with acyclic conjugated dienes.¹⁶²⁹ In the case of BrN₃, both electrophilic and free-radical mechanisms are important,¹⁶³⁰ while with ClN₃ the additions are chiefly free radical.¹⁶³¹ The compound IN₃ also adds to triple bonds to give β -iodo- α,β -unsaturated azides.¹⁶³²

β -Iodo azides can be reduced to aziridines (**167**) with LiAlH₄¹⁶³³ or converted to *N*-alkyl- or *N*-arylaziridines (**168**) by treatment with an alkyl- or aryldichloroborane followed by a base.¹⁶³⁴ In both cases, the azide is first reduced to the corresponding amine (primary or secondary, respectively) and ring closure (**10-31**) follows. With Chloramine T (TsNCl⁻ Na⁺) and 10% of pyridinium bromide perbromide, however, the reaction with alkenes give an *N*-tosyl aziridine directly.¹⁶³⁵

Alkyl halides can be added to alkenes in the presence of a Friedel-Crafts catalyst, most often AlCl_3 .¹⁶³⁶ The yields are best for tertiary R. Secondary R can also be used, but primary R give rearrangement products (as with **11-11**). Methyl and ethyl halides, which cannot rearrange to a more stable secondary or tertiary carbocation, give no reaction at all. The attacking species is the carbocation formed from the alkyl halide and the catalyst (see **11-11**).¹⁶³⁷ The addition therefore follows Markovnikov's rule, with the cation going to the carbon with more hydrogens. Substitution is a side reaction, arising from loss of hydrogen from the carbocation formed when an additional molecule of alkene attacks the initially formed carbocation (**169**). Conjugated dienes can add 1,4.¹⁶³⁸ Triple bonds also undergo the reaction, to give vinylic halides.¹⁶³⁹

Simple polyhalo alkanes, such as CCl_4 , BrCCl_3 , ICF_3 and related molecules, add to alkenes in good yield.¹⁶⁴⁰ These are free-radical additions and require initiation, for example,¹⁶⁴¹ by peroxides, metal halides (e.g., FeCl_2 , CuCl),¹⁶⁴² ruthenium catalysts,¹⁶⁴³ or UV light. The initial attack is by the carbon, and it goes to the carbon with more hydrogens, as in most free-radical attack:

This type of polyhalo alkane adds to halogenated alkenes in the presence of AlCl_3 by an electrophilic mechanism. This is called the *Prins reaction* (not to be confused with the other Prins reaction, **16-54**).¹⁶⁴⁴

α -Iodolactones add to alkenes in the presence of BEt_3/O_2 to give the addition product.¹⁶⁴⁵ Other α -iodoesters add under similar conditions to give the lactone.¹⁶⁴⁶ Iodoesters also add to alkenes in the presence of BEt_3 to give iodo-esters that have not cyclized.¹⁶⁴⁷

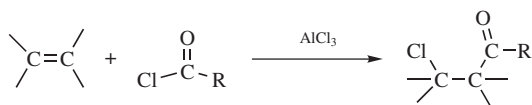

A variant of the free-radical addition method has been used for ring closure (see **15-30**).

For another method of adding R and I to a triple bond (see **15-23**).

15-47 Addition of Acyl Halides (Addition of Halogen, Carbon)

Acyl-halo-addition

Acyl halides have been added to many alkenes, in the presence of Friedel–Crafts catalysts, although polymerization is a problem. The reaction has been applied to straight-chain, branched, and cyclic alkenes, but to very few containing functional groups, other than halogen.¹⁶⁴⁸ The mechanism is similar to that of **15-46**, and, as in that case, substitution competes (**12-16**). Increasing temperature favors substitution,¹⁶⁴⁹ and good yields of addition products can be achieved if the temperature is kept under 0°C . The reaction usually fails with conjugated dienes, since polymerization predominates.¹⁶⁵⁰ Iodo acetates have been formed from alkenes using iodine, $\text{Pb}(\text{OAc})_2$ in acetic acid.¹⁶⁵¹ The reaction can be performed on triple-bond compounds, producing compounds of the form $\text{RCO}-\underset{\substack{| \\ |}}{\text{C}=\text{C}}-\text{Cl}$.¹⁶⁵² A *formyl* group and a halogen can be added to triple bonds by treatment with *N,N*-disubstituted formamides

15-48 Hydroxylation (Addition of Oxygen, Oxygen)

Dihydroxy-addition

There are many reagents that add two OH groups to a double bond.¹⁶⁵⁵ The most common are OsO_4 ¹⁶⁵⁶ and alkaline KMnO_4 ,¹⁶⁵⁷ which give syn addition from the less-hindered side of the double bond. Less substituted double bonds are oxidized more rapidly than more substituted alkenes.¹⁶⁵⁸ Permanganate adds to alkenes to form an intermediate manganate ester (**171**), which is decomposed under alkaline conditions. Bases catalyze the decomposition of **171** by coordinating with the ester. Osmium tetroxide adds rather slowly but almost quantitatively to form a cyclic ester, such as **170**, as an intermediate, which can be isolated,¹⁶⁵⁹ but is usually decomposed solution, with sodium sulfite in ethanol or other reagents. The chief drawback to the use of OsO_4 is expensive and highly toxic, but the reaction is made catalytic in OsO_4 by using *N*-methylmorpholine-*N*-oxide (NMO),¹⁶⁶⁰ *tert*-butyl hydroperoxide in alkaline solution,¹⁶⁶¹ H_2O_2 ,¹⁶⁶² peroxyacid,¹⁶⁶³ flavin and

TEAA,¹⁶⁶⁴ $\text{K}_3\text{Fe}(\text{CN})_6$ ¹⁶⁶⁵ and non-heme iron catalysts.¹⁶⁶⁶ Polymer-bound OsO_4 ,¹⁶⁶⁷ and encapsulated OsO_4 have been shown to give the diol in the presence of NMO,¹⁶⁶⁸ as well as OsO_4^{-2} on an ion exchange resin.¹⁶⁶⁹ Dihydroxylation has also been reported in ionic liquids,¹⁶⁷⁰ and with fluoros osmium tetroxide.¹⁶⁷¹ A catalytic amount of K_2OsO_4 with a Cinchona alkaloid on an ordered inorganic support, in the presence of $\text{K}_3\text{Fe}(\text{CN})_6$, gives the cis-diol.¹⁶⁷² Oxidation of pent-4-en-1-ol to valerolactone was accomplished with Oxone[®] and a catalytic amount of OsO_4 in DMF.¹⁶⁷³

The end-product of the reaction of either potassium permanganate or osmium tetroxide under the conditions described above is a 1,2-diol. Potassium permanganate is a strong oxidizing agent and can oxidize the glycol product¹⁶⁷⁴ (see **19-7** and **19-10**). In acid and neutral solution it always does so; hence glycols must be prepared with alkaline¹⁶⁷⁵ permanganate, but the conditions must be mild. Even so, yields are seldom $>50\%$, although they can be improved with phase-transfer catalysis¹⁶⁷⁶ or increased stirring.¹⁶⁷⁷ The use of ultrasound with permanganate

¹⁶⁷⁴Or give more highly oxidized products, such as α -hydroxy ketones without going through the glycols. See, for example, Wolfe, S.; Ingold, C.F.; Lemieux, R.U. *J. Am. Chem. Soc.* **1981**, *103*, 938; Wolfe, S.; Ingold, C.F. *J. Am. Chem. Soc.* **1981**, *103*, 940. Also see, Lohray, B.B.; Bhushan, V.; Kumar, R.K. *J. Org. Chem.* **1994**, *59*, 1375.

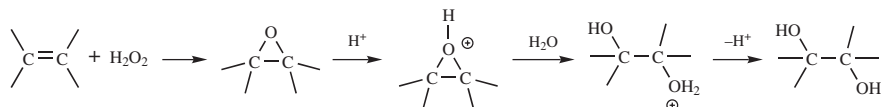

¹⁶⁷⁵The role of the base seems merely to be to inhibit acid-promoted oxidations. The base does not appear to play any part in the mechanism: Taylor, J.E.; Green, R. *Can. J. Chem.* **1985**, *63*, 2777.

¹⁶⁷⁶See, for example, Weber, W.P.; Shepherd, J.P. *Tetrahedron Lett.* **1972**, 4907; Ogino, T.; Mochizuki, K. *Chem. Lett.* **1979**, 443.

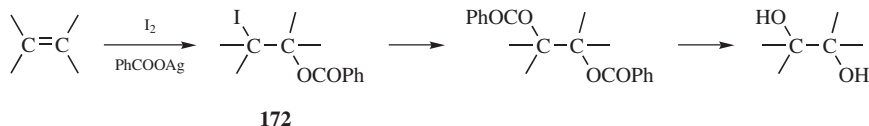

¹⁶⁷⁷Taylor, J.E.; Williams, D.; Edwards, K.; Otonnaa, D.; Samanich, D. *Can. J. Chem.* **1984**, *62*, 11; Taylor, J.E. *Can. J. Chem.* **1984**, *62*, 2641.

dihydroxylation has resulted in good yields of the diol.¹⁶⁷⁸ There is evidence that cyclic esters (**171**) are intermediates for OsO₄ dihydroxylation.¹⁶⁷⁹ This reaction is the basis of the *Baeyer test* for the presence of double bonds. The oxidation is compatible with a number of functional groups, including trichloroacetamides.¹⁶⁸⁰

Anti hydroxylation can be achieved by treatment with H₂O₂ and formic acid. In this case, epoxidation (**15-50**) occurs first, followed by an S_N2 reaction, which results in overall anti addition:

The same result can be achieved in one step with *m*-chloroperoxybenzoic acid and water.¹⁶⁸¹ Overall anti addition can also be achieved by the method of Prévost (the *Prévost reaction*). In this method, the alkene is treated with iodine and silver benzoate in a 1:2 molar ratio. The initial addition is anti and results in a β-halo benzoate (**172**). These can be isolated, and this represents a method of addition of IOCOPh. However, under the normal reaction conditions, the iodine is replaced by a second PhCOO group. This is a nucleophilic substitution reaction, and it operates by the neighboring-group mechanism (p. 446), so the groups are still anti:

Hydrolysis of the ester does not change the configuration. The *Woodward modification* of the Prévost reaction is similar, but results in overall syn hydroxylation.¹⁶⁸² The alkene is treated with iodine and silver acetate in a 1:1 molar ratio in acetic acid containing water. Here again, the initial product is a β-halo ester; the addition is anti and a nucleophilic replacement of the iodine occurs. However, in the presence of water, neighboring-group participation is prevented or greatly decreased by solvation of the ester function, and the mechanism is the normal S_N2 process,¹⁶⁸³

¹⁶⁸³For another possible mechanism that accounts for the stereochemical result of the Woodward method, see Woodward, R.B.; Brutcher, Jr., F.V. *J. Am. Chem. Soc.* **1958**, 80, 209.

so the monoacetate is syn and hydrolysis gives the glycol that is the product of overall syn addition. Although the Woodward method results in overall syn addition, the product may be different from that with OsO_4 or KMnO_4 , since the overall syn process is from the more-hindered side of the alkene.¹⁶⁸⁴ Both the Prévost and the Woodward methods¹⁶⁸⁵ have also been carried out in high yields with thallium(I) acetate and thallium(I) benzoate instead of the silver carboxylates.¹⁶⁸⁶ Note that cyclic sulfates can be prepared from alkenes by reaction with PhIO and $\text{SO}_3 \cdot \text{DMF}$.¹⁶⁸⁷

With suitable substrates, addition of two OH groups creates one new stereogenic center from a terminal alkene and two new stereogenic centers from internal alkenes. Addition to alkenes of the form $\text{RCH}=\text{CH}_2$ has been made enantioselective, and addition to $\text{RCH}=\text{CHR}'$ both diastereoselective¹⁶⁸⁸ and enantioselective,¹⁶⁸⁹ by using chiral additives or chiral catalysts,¹⁶⁹⁰ such as **173**, **174** (derivatives of the

naturally occurring quinine and quinuclidine),¹⁶⁹¹ along with OsO₄, in what is called *Sharpless asymmetric dihydroxylation*.¹⁶⁹² Other chiral ligands¹⁶⁹³ have also been used, as well as polymer¹⁶⁹⁴ and silica-bound¹⁶⁹⁵ *Cinchona* alkaloids. These amines bind to the OsO₄ *in situ* as chiral ligands, causing it to add asymmetrically.¹⁶⁹⁶ This has been done both with the stoichiometric and with the catalytic method.¹⁶⁹⁷ The catalytic method has been extended to conjugated dienes, which give tetrahydroxy products diastereoselectively,¹⁶⁹⁸ and to conjugated ketones.¹⁶⁹⁹ Asymmetric dihydroxylation has also been reported with chiral alkenes.¹⁷⁰⁰ Ligands **173** and **174** not only cause enantioselective addition, but also accelerate the reaction, so that they may be useful even where enantioselective addition is not required.¹⁷⁰¹ Although **173** and **174** are not enantiomers, they give enantioselective addition to a given alkene in the opposite sense; for example, styrene predominantly gave the (*R*)-diol with **173**, and the

(*S*)-diol with **174**.¹⁷⁰² Note that ionic liquids have been used in asymmetric dihydroxylation.¹⁷⁰³

Two phthalazine derivatives,¹⁷⁰⁴ (DHQD)₂PHAL (**175**) and (DHQ)₂PHAL (**176**) used in conjunction with an osmium reagent improve the efficiency and ease of use, and are commercial available as AD-mix-βTM (using **175**) and AD-mix-αTM (using **176**). Catalyst **175** is prepared from dihydroquinidine (DHQD) and 1,4-dichlorophthalazine (PHAL), and **176** is prepared from dihydroquinine (DHQ) and PHAL. The actual oxidation labeled AD-mix α- or β-uses **176** or **175**, respectively, mixed with potassium osmate [K₂OsO₂(OH)₄], powdered K₃Fe(CN)₆, and powdered K₂CO₃ in an aqueous solvent mixture.¹⁷⁰⁵ These additives have been used in conjunction with microencapsulated OsO₄,¹⁷⁰⁵ and polymer bound **175** has been used.¹⁷⁰⁶ A catalytic amount of flavin has been used.¹⁷⁰⁷ Both **175**¹⁷⁰⁸ and **176**¹⁷⁰⁹ have been used to generate diols with high enantioselectivity. Oxidation of a terminal alkene with AD-mix and then oxidation with TEMPO/NaOCl/NaOCl₂ leads to α-hydroxyl carboxylic acids with high enantioselectivity.¹⁷¹⁰

Enantioselective and diastereoselective addition have also been achieved by using preformed derivatives of OsO₄, already containing chiral ligands,¹⁷¹¹ and by the use of OsO₄ on alkenes that have a chiral group elsewhere in the molecule.¹⁷¹²

Alkenes can also be oxidized with metallic acetates such as lead tetraacetate¹⁷¹³ or thallium(III) acetate¹⁷¹⁴ to give bis(acetates) of glycols.¹⁷¹⁵ Oxidizing agents, such as benzoquinone, MnO₂, or O₂, along with palladium acetate, have been used to convert conjugated dienes to 1,4-diacetoxy-2-alkenes (1,4-addition).¹⁷¹⁶ Sodium periodate and sulfuric acid in aqueous media converts conjugated esters to dihydroxy esters.¹⁷¹⁷ Diols are also produced by the reaction of a terminal alkyne with Bu₃SnH, followed by ozonolysis, followed by reduction with BH₃·SMe₂.¹⁷¹⁸ 1,2-Diols are also generated from terminal alkynes by two sequential reactions with a platinum catalyst, and then a palladium catalyst, both with HSiCl₃, and a final oxidation with H₂O₂–KF.¹⁷¹⁹

1,2-Dithiols can be prepared from alkenes.¹⁷²⁰

groups generates a chiral molecule that can be used as a template for asymmetric syntheses.¹⁷²⁴

OS X, 217.

15-50 Epoxidation (Addition of Oxygen, Oxygen)

epi-Oxy-addition

Alkenes can be epoxidized with many peroxyacids,¹⁷²⁵ of which *m*-chloroperoxybenzoic has been the most often used. The reaction, called the *Prilezhaev reaction*, has wide utility.¹⁷²⁶ Alkyl, aryl, hydroxyl, ester, and other groups may be present, although not amino groups, since these are affected by the reagent. Electron-donating groups increase the rate, and the reaction is particularly rapid with tetraalkyl alkenes. Conditions are mild and yields are high. Other peroxyacids, especially peroxyacetic and peroxybenzoic, are also used; trifluoroperoxyacetic acid¹⁷²⁷ and 3,5-dinitroperoxybenzoic acid¹⁷²⁸ are particularly reactive ones. Transition metal catalysts can facilitate epoxidation of alkenes at low temperatures or with alkenes that may otherwise react sluggishly.¹⁷²⁹ Magnesium monoperoxyphthalate (MMPP)¹⁷³⁰ is commercially available, and has been

shown to be a good substitute for *m*-chloroperoxybenzoic acid in a number of reactions.¹⁷³¹

The one-step mechanism involving a transition state, such as **177**,¹⁷³¹ was proposed by Bartlett.¹⁷³² Evidence for this concerted mechanism is as follows:¹⁷³³ (1) The reaction is second order. If ionization were the rate-determining step, it would be first order in peroxyacid. (2) The reaction readily takes place in nonpolar solvents, where formation of ions is inhibited.¹⁷³⁴ (3) Measurements of the effect on the reaction rate of changes in the substrate structure show that there is no carbocation character in the transition state.¹⁷³⁵ (4) The addition is stereospecific (i.e., a *trans*-alkene gives a *trans*-epoxide and a *cis*-alkene a *cis*-epoxide) even in cases where electron-donating substituents would stabilize a hypothetical carbocation intermediate.¹⁷³⁶ However, where there is an OH group in the allylic or homoallylic position, the stereospecificity diminishes or disappears, with both *cis* and *trans* isomers giving predominantly or exclusively the product where the incoming oxygen is *syn* to the OH group. This probably indicates a transition state in which there is hydrogen bonding between the OH group and the peroxy acid.¹⁷³⁷

In general, peroxides (HOOH and ROOH) are poor reagents for epoxidation of simple alkenes since OH and OR are poor leaving groups in the concerted mechanism shown above.¹⁷³⁸ Aqueous hydrogen peroxide epoxidizes alkenes in the presence of fluorosulfonic compounds, such as $\text{CF}_3\text{CH}_2\text{OH}$ ¹⁷³⁹ or hexafluoroacetone.¹⁷⁴⁰ Transition-metal catalysts¹⁷⁴¹ have been used with alkyl hydroperoxides.¹⁷⁴² In the presence of other reagents,¹⁷⁴³ peroxides give good yields of the epoxide. These coreagents include dicyclohexylcarbodiimide,¹⁷⁴⁴ magnesium aluminates,¹⁷⁴⁵ metalloporphyrins,¹⁷⁴⁶ hydrotalcite¹⁷⁴⁷ with microwave irradiation,¹⁷⁴⁸ fluorosulfonic aryl selenides,¹⁷⁴⁹ and arsines in fluorosulfonic solvents.¹⁷⁵⁰ The catalyst MeReO_3 ¹⁷⁵¹ has been used for epoxidation with sodium percarbonate and pyrazole,¹⁷⁵² with hydrogen peroxide,¹⁷⁵³ and with urea– H_2O_2 .¹⁷⁵⁴ Epoxidation occurs with FeSO_4 /silica,¹⁷⁵⁵ and with N_2O and a zinc catalyst.¹⁷⁵⁶ Epoxidation occurs when alkenes

are treated with oxygen gas, *N*-hydroxyphthalimide, and a mixture of cobalt and molybdenum catalyst.¹⁷⁵⁷

Other epoxidation methods are available. Enzymatic epoxidation¹⁷⁵⁸ and epoxidation with catalytic antibodies¹⁷⁵⁹ have been reported. Chromyl chloride (CrO₂Cl₂) reacts with alkenes, even at –78°C to give an epoxide and numerous side products including chlorohydrins and dichlorides.¹⁷⁶⁰ Several mechanisms have been proposed.¹⁷⁶¹ Epoxidation has been done in ionic liquids using 10% H₂O₂ with MnSO₄¹⁷⁶² or an iron catalyst.¹⁷⁶³ Hypervalent iodine compounds, such as PhI(OAc)₂, in conjunction with a ruthenium catalyst in aqueous media, converts alkenes to epoxides.¹⁷⁶⁴ This reagent has been used in an ionic liquid with a manganese catalyst.¹⁷⁶⁵

Dioxiranes,¹⁷⁶⁶ such as dimethyl dioxirane (**178**),¹⁷⁶⁷ either isolated or generated *in situ*,¹⁷⁶⁸ are important epoxidation reagents. With dimethyloxirane, C–H insertion reactions can occur preferentially.¹⁷⁶⁹ The reaction with alkenes is rapid, mild, safe, and a variety of methods have been developed using an oxidant as a coreagent. The most commonly used coreagent is probably potassium peroxomonosulfate (KHSO₅). Oxone[®] (2 KHSO₅·KHSO₄·K₂SO₄) is a common source of KHSO₅. Oxone[®] reacts with ketones¹⁷⁷⁰ and sodium bicarbonate to convert an alkene

to an epoxide. Oxone[®] also converts alkenes to epoxides in the presence of certain additives, such as *N,N*-dialkylalloxans.¹⁷⁷¹ Oxone, usually with hydrogen peroxide or another similar oxidant, can be used with chiral ketones¹⁷⁷² or aldehydes to convert alkenes to chiral, nonracemic epoxides.¹⁷⁷³ Chiral dioxiranes have reportedly given nonracemic epoxides.¹⁷⁷⁴ Hydrogen peroxide, in the presence of chiral ketones in acetonitrile (or other nitrile solvents), probably converts alkenes to epoxides with good enantioselectivity by *in situ* generation of dioxirane.¹⁷⁷⁵ Epoxidation does not occur in good yields with these reagents in most other solvents, and it is suggested that the active agent that generates dioxirane is peroxyimidic acid MeC(=NH)OOH.¹⁷⁷⁶ Note that benzaldehyde with Chloramine-M¹⁷⁷⁷ will convert alkenes to epoxides.¹⁷⁷⁸ Amines, including chiral amines can be similarly used with aldehydes with aqueous sodium bicarbonate.¹⁷⁷⁹

Oxone[®] oxidizes iminium salts to an oxaziridinium intermediate **179**, which can transfer oxygen to an alkene to form an epoxide and regenerate the iminium salt.¹⁷⁸⁰

This variation has been applied to asymmetric¹⁷⁸¹ epoxidations using chiral iminium salt precursors.¹⁷⁸²

Although *cis*–*trans* isomerization of epoxides is not formally associated with this section, it is clearly a potential problem in the conversion of an alkene to an epoxide. There are several catalysts for this process.¹⁷⁸³

It would be useful if triple bonds could be similarly epoxidized to give oxirenes, but they are not stable compounds.¹⁷⁸⁴ Two of them have been trapped in solid argon matrices at very low temperatures, but they decayed on warming to 35 K.¹⁷⁸⁵ Oxirenes probably form in the reaction,¹⁷⁸⁶ but react further before they can be isolated. Note that oxirenes bear the same relationship to cyclobutadiene that furan does to benzene and may therefore be expected to be antiaromatic (see p. 38).

Conjugated dienes can be epoxidized (1,2-addition), although the reaction is slower than for corresponding alkenes, but α,β -unsaturated ketones do not generally give epoxides when treated with peroxyacids.¹⁷⁸⁷ The epoxidation of α,β -unsaturated ketones with hydrogen peroxide under basic conditions is known as the *Waits–Scheffer epoxidation*, discovered in 1921.¹⁷⁸⁸ This fundamental reaction has been extended to α,β -unsaturated ketones (including quinones), aldehydes, and sulfones.¹⁷⁸⁹ This is a nucleophilic addition by a Michael-type mechanism, involving attack by HO_2^- .¹⁷⁹⁰ This reaction is another example of 1,4-addition of a heteroatom containing species as discussed in **15-31**.

α,β -Unsaturated compounds can be epoxidized alkyl hydroperoxides and a base,¹⁷⁹¹ or with H_2O_2 and a base or heteropoly acids.¹⁷⁹² The reaction has been done in D_2O using sodium bicarbonate with hydrogen peroxide.¹⁷⁹³ The reaction has been done with LiOH and polymer-bound quaternary ammonium salts.¹⁷⁹⁴ Epoxides can also be prepared by treating alkenes with oxygen or with an alkyl peroxide¹⁷⁹⁵ catalyzed by a complex of a transition metal such as V, Mo, Ti, La,¹⁷⁹⁶ or Co.¹⁷⁹⁷ The reaction with oxygen, which can also be carried out without a catalyst, is probably a free-radical process.¹⁷⁹⁸ Conjugated ketones are oxidized to epoxy-ketones with NaBO_3 and tetrahexylammonium hydrogen sulfate,¹⁷⁹⁹ $\text{KF}\cdot\text{Al}_2\text{O}_3$ /*tert*-butyl hydroperoxide.¹⁸⁰⁰ α,β -Unsaturated esters react normally to give glycidic esters.¹⁸⁰¹ When a carbonyl group is elsewhere in the molecule but not conjugated with the double bond, the Baeyer–Villiger reaction (18-19) may compete. Allenes¹⁸⁰² are converted by peroxyacids to allene oxides¹⁸⁰³ or spiro dioxides, both of which species can in certain cases be isolated¹⁸⁰⁴ but more often are unstable under the reaction conditions and react further to give other products.¹⁸⁰⁵

Asymmetric Weitz–Scheffer epoxidation is commonly used for the epoxidation of electron-poor alkenes. Cinchona-derived phase-transfer catalysts, initially used

by Wynberg, are now common.¹⁸⁰⁶ Enantioselectivities can be significantly improved by changes of the catalyst structure as well as the type of oxidant.¹⁸⁰⁷ A Yb-BINOL complex, with *t*-BuOOH led to epoxidation of conjugated ketones with high asymmetric induction,¹⁸⁰⁸ as did a mixture of NaOCl and a *Cinchona* alkaloid.¹⁸⁰⁹ Other enantioselective methods include treatment with diethylzinc, O₂, in the presence of a chiral amino-alcohol, to give the epoxy-ketone.¹⁸¹⁰ Similarly, treatment with aqueous NaOCl¹⁸¹¹ or with an alkyl hydroperoxide¹⁸¹² and a chiral phase-transfer agent leads to chiral nonracemic epoxy-ketones.

Another important asymmetric epoxidation of a conjugated systems is the reaction of alkenes with polyleucine, DBU and urea–H₂O₂, giving an epoxy-carbonyl compound with good enantioselectivity.¹⁸¹³ The hydroperoxide anion epoxidation of conjugated carbonyl compounds with a polyamino acid, such as poly-L-alanine or poly-L-leucine is known as the *Juliá–Colonna epoxidation*.¹⁸¹⁴ Epoxidation of conjugated ketones to give nonracemic epoxy-ketones was done with aq. NaOCl and a *Cinchona* alkaloid derivative as catalyst.¹⁸¹⁵ A triphasic phase-transfer catalysis protocol has also been developed.¹⁸¹⁶ β-Peptides have been used as catalysts in this reaction.¹⁸¹⁷

Allylic alcohols can be converted to epoxy-alcohols with *tert*-butylhydroperoxide on molecular sieves,¹⁸¹⁸ or with peroxy acids.¹⁸¹⁹ The addition of an appropriate chiral ligand to the metal-catalyzed hydroperoxide epoxidation of allylic alcohols leads to high enantioselectivity. This important modification is

known as the *Sharpless asymmetric epoxidation*,¹⁸²⁰ where allylic alcohols are converted to optically active epoxides with excellent enantioselectivity by treatment with *t*-BuOOH, titanium tetrakisopropoxide and optically active diethyl tartrate.¹⁸²¹ The Ti(OCHMe)₂ and diethyl tartrate can be present in catalytic amounts (15–10 mol%) if molecular sieves are present.¹⁸²² Polymer-supported catalysts have also been reported.¹⁸²³ Both (+) and (–) diethyl tartrate are readily available, so either enantiomer of the product can be prepared. The method has been successful for a wide range of primary allylic alcohols, including substrates where the double bond is mono-, di-, tri-, and tetrasubstituted,¹⁸²⁴ and is highly useful in natural product synthesis. The mechanism of the Sharpless epoxidation is believed to involve attack on the substrate by a compound¹⁸²⁵ formed from the titanium alkoxide and the diethyl tartrate to produce a complex that also contains the substrate and the *t*-BuOOH.¹⁸²⁶

Ordinary alkenes (without an allylic OH group) do not give optically active alcohols by the Sharpless protocol because binding to the catalyst is necessary for enantioselectivity. Simple alkenes can be epoxidized enantioselectively with sodium hypochlorite (NaOCl, commercial bleach) and an optically active manganese-complex catalyst.¹⁸²⁷ An important variation of this oxidation uses a manganese–salen complex¹⁸²⁸ with various oxidizing agents, in what is called

the *Jacobsen–Katsuki reaction*.¹⁸²⁹ Apart from the commonly used NaOCl, urea–H₂O₂ has been used.¹⁸³⁰ With this reaction, simple alkenes can be epoxidized with high enantioselectivity.¹⁸³¹ The mechanism of this reaction has been examined.¹⁸³² Radical intermediates have been suggested for this reaction,¹⁸³³ A polymer-bound Mn^(III)–salen complex, in conjunction with NaOCl, has been used for asymmetric epoxidation.¹⁸³⁴ Chromium–salen complexes¹⁸³⁵ and ruthenium–salen complexes¹⁸³⁶ have been used for epoxidation. Manganese porphyrin complexes have also been used.¹⁸³⁷ Cobalt complexes give similar results.¹⁸³⁸ A related epoxidation reaction used an iron complex with molecular oxygen and isopropanol.¹⁸³⁹ Nonracemic epoxides can be prepared from racemic epoxides with salen–cobalt(II) catalysts following a modified procedure for kinetic resolution.¹⁸⁴⁰

In a different type of reaction, alkenes are photooxygenated (with singlet O₂, see **14-7**) in the presence of a Ti, V, or Mo complex to give epoxy alcohols, such as **180**, formally derived from allylic hydroxylation followed by epoxidation.¹⁸⁴¹ In other cases, modification of the procedure gives simple epoxidation.¹⁸⁴² Alkenes react with aldehydes and oxygen, with palladium-on-silica¹⁸⁴³ or a ruthenium catalyst,¹⁸⁴⁴

to give the epoxide.

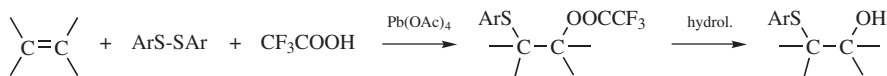

Thiiranes can be prepared directly from alkenes using specialized reagents.¹⁸⁴⁵ Thiourea with a tin catalyst gives the thiirane, for example.¹⁸⁴⁶ Interestingly, internal alkynes were converted to 1,2-dichorothiiranes by reaction with S_2Cl_2 (sulfur monochloride).¹⁸⁴⁷ It is noted that epoxides are converted to thiiranes with ammonium thiocyanate and a cerium complex.¹⁸⁴⁸ A trans-thiiration reaction occurs with a molybdenum catalyst, in which an alkene reacts with styrene thiirane to give the new thiirane.¹⁸⁴⁹

15-51 Hydroxysulfenylation (Addition of Oxygen, Sulfur)

Hydroxy-arythio-addition (overall transformation)

A hydroxy and an arylthio group can be added to a double bond by treatment with an aryl disulfide and lead tetraacetate in the presence of trifluoroacetic acid.¹⁸⁵⁰ Manganese and copper acetates have been used instead of $Pb(OAc)_4$.¹⁸⁵¹ Addition of the groups OH and RSO has been achieved by treatment of alkenes with O_2 and a thiol RSH .¹⁸⁵² Two RS groups were added, to give *vic*-dithiols, by treatment of the alkene with a disulfide $RSSR$ and BF_3 -etherate.¹⁸⁵³ This reaction

has been carried out internally.¹⁸⁵⁴ In a similar manner, reaction of alkenes with ceric ammonium nitrate, diphenyl diselenide in methanol leads to vicinally substituted phenylselenyl methyl ethers.¹⁸⁵⁵ Dimethyl diselenide adds to alkenes to form vicinal bis-methylselenyl compounds, in the presence of tin tetrachloride.¹⁸⁵⁶

Halo-ethers can be formed by the reaction of alkenyl alcohols with various reagents. Hept-6-en-1-ol reacts with (collidine)₂I⁺PF₆⁻, for example, to form 2-iodomethyl-1-oxacycloheptane.¹⁸⁵⁷

15-52 Oxyamination (Addition of Oxygen, Nitrogen)

Tosylamino-hydroxy-addition

N-Tosylated β-hydroxy alkylamines (which can be easily hydrolyzed to β-hydroxyamines¹⁸⁵⁸) can be prepared¹⁸⁵⁹ by treatment of alkenes with the trihydrate of Chloramine-T (*N*-chloro-*p*-toluenesulfonamide sodium salt)¹⁸⁶⁰ and a catalytic amount of OsO₄.¹⁸⁶⁰ In some cases, yields can be improved by the use of phase-transfer catalysis.¹⁸⁶¹ The reaction has been carried out enantioselectively.¹⁸⁶² Alkenes can be converted to amido alcohols enantioselectivity by modification of this basic scheme. The *Sharpless asymmetric aminohydroxylation* employs a catalyst consisting of *Cinchona* alkaloid derived ligands and an osmium species in combination with a stoichiometric nitrogen source that also functions as the oxidant.¹⁸⁶³ The reaction of a carbamate with (DHQ)₂PHAL (**176**) and the osmium compound, with NaOH and *tert*-butyl hypochlorite, leads to a diastereomeric mixture of amido alcohols **181** and **182**, each formed with high enantioselectivity.¹⁸⁶⁴ In general, the nitrogen adds to the less sterically hindered carbon of the alkene to give the major product. *N*-Bromoamides, in the presence of a catalytic amount of (DHQ)₂PHAL

and LiOH converts conjugated esters to β -amido- α -hydroxy esters with good enantioselectivity.¹⁸⁶⁵ In another procedure, certain β -hydroxy secondary alkylamines can be prepared by treatment of alkenes with the osmium compound t -Bu-N=OsO₃, followed by reductive cleavage with LiAlH₄ of the initially formed osmic esters.¹⁸⁶⁶ It is presumed that Ts-N=OsO₃ is an intermediate in the Chloramine-T reaction. Another oxyamination reaction involves treatment of a palladium complex of the alkene with a secondary or primary amine, followed by lead tetraacetate or another oxidant.¹⁸⁶⁷

The organolanthanide-catalyzed alkene hydroamination has been reported.¹⁸⁶⁸ With this approach, amino alkenes (not enamines) can be cyclized to form cyclic amines,¹⁸⁶⁹ and amino alkynes lead to cyclic imine.¹⁸⁷⁰ The use of synthesized C-1¹⁸⁷¹ and C-2 symmetric¹⁸⁷² chiral organolanthanide complexes give the amino alcohol with good enantioselectivity.

β -Amino alcohols can be prepared by treatment of an alkene with a reagent prepared from HgO and HBF₄ along with aniline to give an aminomercurial

compound $\text{PhHN}-\overset{\text{||}}{\underset{\text{||}}{\text{C}}}-\text{C}-\text{HgBF}_4$ (aminomercuration; see 15-7) which is hydrolyzed

to $\text{PhHN}-\overset{\text{|}}{\underset{\text{|}}{\text{C}}}-\overset{\text{|}}{\underset{\text{|}}{\text{C}}}-\text{OH}$.¹⁸⁷³ The use of an alcohol instead of water gives the corresponding

amino ether. β -Azido alcohols are prepared by the reaction of an alkene with $\text{Me}_3\text{SiOOSiMe}_3$, Me_3SiN_3 , and 20% $(\text{Cl}_2\text{SnO})_n$, followed by treatment with aqueous acetic acid.¹⁸⁷⁴

OS VII, 223, 375.

15-53 Diamination (Addition of Nitrogen, Nitrogen)

Di(alkylarylamino)-addition

Primary (R = H) and secondary aromatic amines react with alkenes in the presence of thallium(III) acetate to give *vic*-diamines in good yields.¹⁸⁷⁵ The reaction is not successful for primary aliphatic amines. In another procedure, alkenes can be diaminated by treatment with the osmium compounds R_3NOsO (R = *t*-Bu) and R_2NOsO_2 ,¹⁸⁷⁶ analogous to the osmium compound mentioned at 15-52.¹⁸⁷⁷ The palladium-promoted method of 15-52 has also been extended to diamination.¹⁸⁷⁸ Alkenes can also be diaminated¹⁸⁷⁹ indirectly by treatment of the aminomercurial compound mentioned in 15-52 with a primary or secondary aromatic amine.¹⁸⁸⁰ The reaction of an alkene with *N*-arylsulfonyl dichloroamines, $\text{ArSO}_2\text{NCl}_2$, followed by reaction with aqueous Na_2SO_3 , gives the *anti-vic*-diacetamide.¹⁸⁸¹

Two azido groups can be added to double bonds by treatment with sodium azide and iodosobenzene in acetic acid, $\text{C}=\text{C} + \text{NaN}_3 + \text{PhIO} \rightarrow \text{N}_3-\text{C}-\text{C}-\text{N}_3$.¹⁸⁸²

15-54 Formation of Aziridines (Addition of Nitrogen, Nitrogen)*epi-Arylimino-addition*, and so on.

Aziridines can be prepared directly from double-bond compounds by photolysis or thermolysis of a mixture of the substrate and an azide.¹⁸⁸³ The reaction has been carried out with R = aryl, cyano, EtOOC, and RSO₂, as well as other groups. The reaction can take place by at least two pathways.

In one pathway a 1,3-dipolar addition (**15-58**) takes place to give a triazoline (which can be isolated), followed thermal by extrusion of nitrogen (**17-34**). Evidence for the nitrene pathway is most compelling for R = acyl groups. In the other, the azide is converted to a nitrene, which adds to the double bond in a manner analogous to that of carbene addition (**15-64**). Sulfonyloxy amines, such as ArSO₂ONHCO₂Et, form an aziridine when treated with CaO in the presence of a conjugated carbonyl compound.¹⁸⁸⁴ In the presence of copper,¹⁸⁸⁵ cobalt,¹⁸⁸⁶ or rhodium complexes,¹⁸⁸⁷ ethyl diazoacetate adds to imines to give aziridines. Diazirines (p. 288) with *n*-butyllithium converted conjugated amides to the α,β -aziridino amide.¹⁸⁸⁸ Calcium oxide has also been used to generate the nitrene,¹⁸⁸⁹ including nitrene precursors that have an attached chiral ester.¹⁸⁹⁰ Other specialized reagents have also been used.¹⁸⁹¹ As discussed on p. 293, singlet nitrenes add stereospecifically while triplet nitrenes do not. Diphenyl sulfimide (Ph₂SNH) converts

Michael-type substrates to the corresponding aziridines.¹⁸⁹² Aminonitrenes ($R_2NN:$) have been shown to add to alkenes¹⁸⁹³ to give *N*-substituted aziridines and to triple bonds to give 1-azirines, which arise from rearrangement of the initially formed 2-azirines.¹⁸⁹⁴ Like oxirenes (see **15-50**), 2-azirines are unstable, probably because of anti-aromaticity. 1-Azirines can be reduced to give chiral aziridines.¹⁸⁹⁵

An alternative preparation of aziridines reacts an alkene with iodine and chloramine-T, generating the corresponding *N*-tosyl aziridine.¹⁸⁹⁶ Chloramine T and NBS also gives the *N*-tosyl aziridine,¹⁸⁹⁷ and bromamine-T ($TsNBr^-Na^+$) has been used in a similar manner,¹⁸⁹⁸ and also $TsNIK$.¹⁸⁹⁹ Diazoalkanes react with imines to give aziridines.¹⁹⁰⁰ Another useful reagent is $NsN=I\text{Ph}$, which reacts with alkenes in the presence of rhodium compounds¹⁹⁰¹ or $Cu(OTf)_2$ ¹⁹⁰² to give *N*-Ns aziridines. Other sulfonamide reagents can be used,¹⁹⁰³ including $PhI=NTs$.¹⁹⁰⁴ Enantioselective aziridination is possible using this reaction with

chiral ligands.¹⁹⁰⁵ This reagent has been used in ionic liquids with a copper catalyst.¹⁹⁰⁶ Such reactions are catalyzed by palladium¹⁹⁰⁷ and methyl trioxorhenium (MeReO₃) can be used in these reactions.¹⁹⁰⁸ Manganese–salen catalysts have also been used with this reagent.¹⁹⁰⁹ A nitrido manganese–salen complex was also used with ditosyl anhydride, converting a conjugated diene to an allylic *N*-tosylaziridine.¹⁹¹⁰

Nitrenes can also add to aromatic rings to give ring-expansion products analogous to those mentioned in **15-62**.¹⁹¹¹

OS VI, 56.

15-55 Aminosulfenylation (Addition of Nitrogen, Sulfur)

Arylamino-arylthio-addition

An amino and an arylthio group can be added to a double bond by treatment with a sulfenamide PhSNHAr in the presence of BF₃-etherate.¹⁹¹² The addition is anti, and the mechanism probably involves a thiiranium ion.¹⁹¹³ In another aminosulfenylation procedure, the substrate is treated with dimethyl(methylthio)sulfonium fluoroborate (MeSSMe₂ BF₄⁻) and ammonia or an amine,¹⁹¹⁴ the latter acting as a nucleophile. This reaction was extended to other nucleophiles:¹⁹¹⁵ N₃⁻,¹⁹¹⁶

NO_2^- , CN^- , OH^- , and OAc^- to give $\text{MeS}-\overset{\text{O}}{\underset{\text{O}}{\text{C}}}-\overset{\text{O}}{\underset{\text{O}}{\text{C}}}-\text{A}$, where $\text{A} = \text{N}_3, \text{NO}_2, \text{CN}, \text{OH}$, and OAc , respectively. An RS ($\text{R} = \text{alkyl or aryl}$) and an NHCOMe group have been added in an electrochemical procedure.¹⁹¹⁷

15-56 Acylacyloxylation and Acylamidation (Addition of Oxygen, Carbon, or Nitrogen, Carbon)

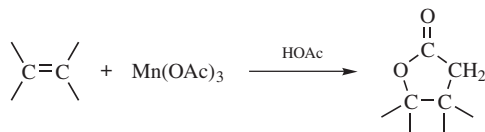

Acyl-acyloxy-addition

An acyl and an acyloxy group can be added to a double bond by treatment with an acyl fluoroborate and acetic anhydride.¹⁹¹⁸ As expected, the addition follows Markovnikov's rule, with the electrophile Ac^+ going to the carbon with more hydrogens. In an analogous reaction, an acyl and an amido group can be added to give **183**, if a nitrile is used in place of the anhydride. Similarly, halo acetoxylation is known.¹⁹¹⁹ This reaction has also been carried out on triple bonds, to give the unsaturated analogs of **183** (syn addition).¹⁹²⁰

15-57 The Conversion of Alkenes to γ -Lactones (Addition of Oxygen, Carbon)

This reaction is clearly related to forming esters and lactones by reaction of carboxylic acids with alkenes (**15-6**), but the manganese reagent leads to

differences. Alkenes react with manganese(III) acetate to give γ -lactones.¹⁹²¹ The mechanism is probably free radical, involving addition of $\bullet\text{CH}_2\text{COOH}$ to the double bond. Ultrasound improves the efficiency of the reaction.¹⁹²² In a related reaction, cyclohexene reacted with $\text{MeO}_2\text{CCH}_2\text{CO}_2\text{K}$ and $\text{Mn}(\text{OAc})_3$ to give an α -carbomethoxy bicyclic lactone.¹⁹²³ The use of dimethyl malonate and ultrasound in this reaction gave the same type of product.¹⁹²⁴ Lactone formation has also been accomplished by treatment of alkenes with α -bromo carboxylic acids in the presence of benzoyl peroxide as catalyst,¹⁹²⁵ and with alkylidene chromium pentacarbonyl complexes.¹⁹²⁶ Alkenes can also be converted to γ -lactones by indirect routes.¹⁹²⁷ Chromium-carbene complexes add to alkenes to give β -lactones using ultrasound.¹⁹²⁸

An intramolecular variation of this reaction is known, involving amides, which generates a lactam.¹⁹²⁹

OS VII, 400.

For addition of aldehydes and ketones, see the Prins reaction (16-54), and reactions 16-95 and 16-96.

15-58 1,3-Dipolar Addition (Addition of Oxygen, Nitrogen, Carbon)

There are a large group of reactions ($[3 + 2]$ -cycloadditions) in which five-membered heterocyclic compounds are prepared by addition of 1,3-dipolar compounds to double bonds. This reaction is quite useful in the synthesis of alkaloids,¹⁹³⁰ including asymmetric syntheses.¹⁹³¹ These dipolar compounds have a

sequence of three atoms $a-b-c$, of which a has a sextet of electrons in the outer shell and c an octet with at least one unshared pair (see Table 15.3).¹⁹³² The reaction can then be formulated as shown to generate **184**. Note that the initial reaction of potassium permanganate (**15-48**) occurs by [3 + 2]-cycloaddition to give a manganate ester (**171**).¹⁹³³ [3+2]-Cycloadditions occur with other metal oxides.¹⁹³⁴ Hydrazones have also been reported to give [3 + 2]-cycloadditions.¹⁹³⁵

1,3-Dipoles of the type shown in Table 15.3 have an atom with six electrons in the outer shell, which is usually unstable, and such compounds will delocalize the charge to alleviate this electronic arrangement (they are resonance stabilized). 1,3-Dipolar compounds can be divided into two main types:

1. Those in which the dipolar canonical form has a double bond on the sextet atom and the other canonical form has a triple bond on that atom:

nitrogen; hence there are six types. Among these are azides ($a = b = c = \text{N}$) and diazoalkanes.

2. Those in which the dipolar canonical form has a single bond on the sextet atom and the other form has a double bond:

Here b can be nitrogen or oxygen, and a and c can be nitrogen, oxygen, or carbon, but there are only 12 types, since, for example, $\text{N}-\text{N}-\text{C}$ is only another form of $\text{C}-\text{N}-\text{N}$. Examples are shown in Table 15.3.

Of the 18 systems, some of which are unstable and must be generated *in situ*,¹⁹⁴² the reaction has been accomplished for at least 15, but not in all cases with a carbon–carbon double bond (the reaction also can be carried out with other double bonds¹⁹⁴³). Not all alkenes undergo 1,3-dipolar addition equally well. The reaction is most successful for those that are good dienophiles in the Diels–Alder reaction (15-60). The addition is stereospecific and syn, and the mechanism is probably a one-step concerted process,¹⁹⁴⁴ as illustrated above,¹⁹⁴⁵ largely controlled by Frontier Molecular Orbital considerations.¹⁹⁴⁶ In-plane aromaticity has been invoked for these dipolar cycloadditions.¹⁹⁴⁷ As expected for this type of mechanism, the rates do not vary much with changes in solvent,¹⁹⁴⁸ although rate acceleration has been observed in ionic liquids.¹⁹⁴⁹ Nitrile oxide cycloadditions have also been done in supercritical carbon dioxide.¹⁹⁵⁰ There are no simple rules

covering orientation in 1,3-dipolar additions. The regioselectivity has been explained by molecular-orbital treatments,¹⁹⁵¹ where overlap of the largest orbital coefficients of the atoms forming the new bonds leads to the major regioisomer. When the 1,3-dipolar compound is a thiocarbonyl ylid ($R_2C=S^+-CH_2^-$) the addition has been shown to be nonstereospecific with certain substrates but stereospecific with others, indicating a nonsynchronous mechanism in these cases, and in fact, a diionic intermediate (see mechanism *c* on p. 1224) has been trapped in one such case.¹⁹⁵² In a theoretical study of the 1,3-dipolar cycloadditions (diazomethane and ethene; fulminic acid [$H-C\equiv N-O$] and ethyne),¹⁹⁵³ calculations based on valence bond descriptions suggest that many concerted 1,3-dipolar cycloaddition reactions follow an electronic heterolytic mechanism where the movement of well-identifiable orbital pairs are retained along the entire reaction path from reactants to product.¹⁹⁵⁴

An antibody-catalyzed [3 + 2]-cycloaddition has been reported.¹⁹⁵⁵ Metal assisted dipolar additions are also known.¹⁹⁵⁶

Many of the cycloadducts formed from the dipoles in Table 15.3 are unstable, leading to other products. The reaction of alkyl azides with alkenes generates triazolines (**15-54**), which extrude nitrogen ($N\equiv N$) upon heating or photolysis to give an aziridine.

[3 + 2]-Cycloaddition reactions occur intramolecularly to generate bicyclic and polycyclic compounds.¹⁹⁵⁷ The intramolecular cycloaddition of azomethine imines give bicyclic pyrrolidines for example.¹⁹⁵⁸ When diazoalkanes, including diazo acetates such as N_2CHCO_2Et react with an alkene and a chromium catalyst the initially formed product is a five-membered ring, a pyrazoline. Pyrazolines are generally unstable and extrusion of nitrogen leads to a cyclopropane.¹⁹⁵⁹

There are many cases where the [3 + 2]-cycloaddition leads to cycloadducts with high enantioselectivity.¹⁹⁶⁰ Cycloaddition of diazo esters with a cobalt catalyst having a chiral ligand leads to cyclopropane derivatives with good enantioselectivity.¹⁹⁶¹

Cycloaddition of nitrones and pyrazolinones with a copper catalyst and a chiral ligand leads to pyrrolidine derivatives with good enantioselectivity.¹⁹⁶²

Conjugated dienes generally give exclusive 1,2-addition, although 1,4 addition (a [3 + 4]-cycloaddition) has been reported.¹⁹⁶³ Carbon-carbon triple bonds can also undergo 1,3-dipolar addition.¹⁹⁶⁴ For example, azides react to give triazoles, **185**.

The 1,3-dipolar reagent can in some cases be generated by the *in situ* opening of a suitable three-membered ring system. For example, aziridines open to give a zwitterion, such as **186**, which can add to activated double bonds to give pyrrolidines.¹⁹⁶⁵

Aziridines also add to $\text{C}\equiv\text{C}$ triple bonds as well as to other unsaturated linkages, including $\text{C}=\text{O}$, $\text{C}=\text{N}$, and $\text{C}\equiv\text{N}$.¹⁹⁶⁶ In some of these reactions it is a C–N bond of the aziridine that opens rather than the C–C bond.

For other [3 + 2]-cycloadditions, see **15-59**.

See also, the series *Advances in Cycloaddition*.

15-59 All-Carbon [3 + 2]-Cycloadditions¹⁹⁶⁸

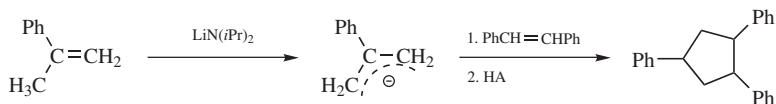

Several methods have been reported for the formation of cyclopentanes by [3 + 2]-cycloadditions.¹⁹⁶⁹ Heating a conjugated ketone with trialkylphosphines generates an intermediate that adds to conjugated alkynes.¹⁹⁷⁰ One type involves reagents that produce intermediates **187** or **188**.¹⁹⁷¹ A synthetically useful example¹⁹⁷² uses 2-[(trimethylsilyl)methyl]-2-propen-1-yl acetate (**191**) (which is commercially available) and a palladium or other transition-metal catalyst to generate **187** or **188**, which adds to double bonds, to give, in

good yields, cyclopentanes with an exocyclic double bond. Note that **95** also reacts with *N*-tosyl aziridines, with 20% *n*-butyllithium and 10% of Pd(OAc)₂, to give a vinylidene piperidine derivative.¹⁹⁷³ Similar or identical intermediates generated from bicyclic azo compounds **189** (see 17-34) or methylenecyclopropane **190**¹⁹⁷⁴ also add to activated double bonds. With suitable substrates the addition can be enantioselective.¹⁹⁷⁵

In a different type of procedure, [3 + 2]-cycloadditions are performed with allylic anions. Such reactions are called 1,3-anionic cycloadditions.¹⁹⁷⁶ For example, α -methylstyrene adds to stilbene on treatment with the strong base LDA.¹⁹⁷⁷

¹⁹⁷⁷Eidenschink, R.; Kauffmann, T. *Angew. Chem. Int. Ed.* **1972**, *11*, 292.

The mechanism can be outlined as

In the case above, **192** is protonated in the last step by the acid HA, but if the acid is omitted and a suitable nucleofuge is present, it may leave, resulting in a cyclopentene.¹⁹⁷⁸ In these cases the reagent is an allylic anion, but similar [3 + 2]-cycloadditions involving allylic cations have also been reported.¹⁹⁷⁹

OS VIII,173, 347.

15-60 The Diels–Alder Reaction

(4 + 2)cyclo-Ethylene-1/4/addition or (4 + 2)cyclo-[But-2-ene-1,4-diyl]-1/2/addition, and so on.

In the prototype *Diels–Alder reaction* the double bond of an alkene adds 1,4 to a conjugated diene (a [4 + 2]-cycloaddition),¹⁹⁸⁰ so the product is always a cyclohexene. The cycloaddition is not limited to alkenes or to dienes (see **15-61**), but the substrate that reacts with the diene is called a *dienophile*. The reaction is of

¹⁹⁷⁸See, for example, Padwa, A.; Yeske, P.E. *J. Am. Chem. Soc.* **1988**, *110*, 1617; Beak, P.; Burg, D.A. *J. Org. Chem.* **1989**, *54*, 1647.

very broad scope¹⁹⁸¹ and reactivity of dienes and dienophiles can be predicted based on analysis of the HOMOs¹⁹⁸² and LUMOs of these species (frontier molecular orbital theory).¹⁹⁸³ Ethylene and simple alkenes make poor dienophiles, unless high temperatures and/or pressures are used. Most dienophiles are of the form $\begin{array}{c} \text{---C=C---Z} \\ | \quad | \end{array}$ or $\begin{array}{c} \text{Z---C=C---Z'} \\ | \quad | \end{array}$, where Z and Z' are electron-withdrawing groups,¹⁹⁸⁴ such as CHO, COR,¹⁹⁸⁵ COOH, COOR, COCl, COAr, CN,¹⁹⁸⁶ NO₂,¹⁹⁸⁷ Ar, CH₂OH, CH₂Cl, CH₂NH₂, CH₂CN, CH₂COOH, halogen, PO(OEt)₂,¹⁹⁸⁸ or C=C. In the last case, the dienophile is itself a diene.¹⁹⁸⁹ Particularly common dienophiles are maleic anhydride¹⁹⁹⁰ and quinones.¹⁹⁹¹ Triple bond compounds ($\text{---C}\equiv\text{C---Z}$ or $\text{Z---C}\equiv\text{C---Z'}$)

may be dienophiles,¹⁹⁹² generating nonconjugated cyclohexadienes (**193**), and this reaction can be catalyzed by transition-metal compounds.¹⁹⁹³ Allenes react as dienophiles, but without activating groups are very poor dienophiles.¹⁹⁹⁴

¹⁹⁹⁴For a review of Allenes as dienes or dienophiles, see Hopf, H., in Landor, S.R. *The Chemistry of Allenes*, Vol. 2, Academic Press, NY, **1982**, pp. 563–577. See Nendel, M.; Tolbert, L.M.; Herring, L.E.; Islam, Md.N.; Houk, K.N. *J. Org. Chem.* **1999**, 64, 976.

Ketenes, however, do not undergo Diels–Alder reactions.¹⁹⁹⁵ Benzyne, although not isolable, act as dienophiles and can be trapped with dienes,¹⁹⁹⁶ for example,

The low reactivity of simple alkenes can be overcome by incorporating an electron-withdrawing group to facilitate the cycloaddition, but a group that can be removed after the cycloaddition. An example is phenyl vinyl sulfone $\text{PhSO}_2\text{CH}=\text{CH}_2$.¹⁹⁹⁷ The PhSO_2 group can be easily removed with Na-Hg after the ring-closure reaction. Similarly, phenyl vinyl sulfoxide ($\text{PhSOCH}=\text{CH}_2$) can be used as a synthon for acetylene.¹⁹⁹⁸ In this case PhSOH is lost from the sulfoxide product (17-12).

Electron-donating substituents in the diene accelerate the reaction; electron-withdrawing groups retard it.¹⁹⁹⁹ For the dienophile it is just the reverse: donating groups decrease the rate, and withdrawing groups increase it. The cisoid conformation is required for the cycloaddition,²⁰⁰⁰ and acyclic dienes are conformationally mobile so the cisoid conformation will be available. Cyclic dienes, in which the cisoid conformation is built in, usually react faster than the corresponding open-chain compounds, which have to achieve the cisoid conformation by rotation.²⁰⁰¹ Dienes can be open-chain, inner-ring (e.g., **194**), outer-ring²⁰⁰² (e.g., **195**), across

¹⁹⁹⁵Ketenes react with conjugated dienes to give 1,2-addition (see 15–49).

rings (e.g., **196**), or inner-outer (e.g., **197**), except that they may not be frozen into a transoid conformation (see p. 1201). They need no special activating groups, and nearly all conjugated dienes undergo the reaction with suitable dienophiles.²⁰⁰³

In most Diels–Alder reactions,²⁰⁰⁴ no catalyst is needed, but Lewis acids are effective catalysts in many cases, particularly those in which Z in the dienophile is a C=O or C=N group. A Lewis acid catalyst usually increases both the regioselectivity of the reaction (in the sense given above) and the extent of endo addition,²⁰⁰⁵ and, in the case of enantioselective reactions, the extent of enantioselectivity. It has been shown that InCl₃ is an effective catalyst for aqueous Diels–Alder reactions,²⁰⁰⁶ which is suitable for ionic Diels–Alder reactions,²⁰⁰⁷ and there are other Lewis acid catalysts that are effective in water.²⁰⁰⁸ Brønsted acids have also been used to accelerate the rate of the Diels–Alder reaction.²⁰⁰⁹ Lanthanum triflate [La(OTf)₃] has been reported as a reusable catalyst²⁰¹⁰ and Me₃SiNTf₂ has been used as a green Lewis acid catalyst.²⁰¹¹ Cationic Diels–Alder catalysts have been developed, particularly oxazaborolidine catalysts.²⁰¹² Some Diels–Alder reactions can also be catalyzed by the addition of a stable cation radical,²⁰¹³ for

on the reaction has been examined²⁰³⁰ as has micellar effects.²⁰³¹ Another alternative reaction medium is the use of 5 M LiClO₄ in Et₂O as solvent,²⁰³² An alternative to lithium perchlorate in ether is lithium triflate in acetonitrile.²⁰³³ The addition of HPO₄⁻ to an aqueous ethanol solution has also been shown to give an small rate enhancement.²⁰³⁴ This appears to be the only case where an anion is responsible for a rate enhancement. The *retro*-Diels–Alder reaction has also been done in water.²⁰³⁵

It is noted that the Diels–Alder reaction has been done with supercritical CO₂²⁰³⁶ and with supercritical water²⁰³⁷ as solvents. Diels–Alder reactions on solid supports have also been reported,²⁰³⁸ and zeolites have been used in conjunction with catalytic agents.²⁰³⁹ Alumina has been used to promote Diels–Alder reactions.²⁰⁴⁰ Diels–Alder reactions can be done in ionic liquids,²⁰⁴¹ including asymmetric Diels–Alder reactions.²⁰⁴²

When an unsymmetrical diene adds to an unsymmetrical dienophile, regioisomeric products (not counting stereoisomers) are possible. Rearrangements have been encountered in some cases.²⁰⁴³ In simple cases, 1-substituted dienes give cyclohexenes with a 1,2- and a 1,3- substitution pattern. 2-Substituted dienes

lead to 1,4- and 1,3-disubstituted products.

Although mixtures are often obtained, usually one predominates, the one indicated above, but selectivity depends on the nature of the substituents on both diene and alkene. This regioselectivity, in which the “ortho” or “para” product is favored over the “meta,” has been explained by molecular-orbital considerations.²⁰⁴⁴ When X = NO₂, regioselectivity to give the “ortho” or “para” product was very high at room temperature, and this method, combined with subsequent removal of the NO₂ (see **19-67**) has been used to perform regioselective Diels–Alder reactions.²⁰⁴⁵

The stereochemistry of the Diels–Alder reaction can be considered from several aspects:²⁰⁴⁶

1. With respect to the dienophile, the addition is stereospecifically syn, with very few exceptions.²⁰⁴⁷ This means that groups that are cis in the alkene will be cis in the cyclohexene ring, (A–B and C–D) and groups that are trans in the alkene will be trans in the cyclohexene ring (A–D and C–B).

2. With respect to 1,4-disubstituted dienes, fewer cases have been investigated, but here too the reaction is stereospecific and syn. Thus, *trans*, *trans*-1,4-diphenylbutadiene gives *cis*-1,4-diphenylcyclohexene derivatives. This

²⁰⁴⁶See Smith, M.B. *Organic Synthesis*, 2nd ed., McGraw-Hill, NY, **2001**, pp. 933–940, 968–977; Bakalova, S.M.; Santos, A.G. *J. Org. Chem.* **2004**, *69*, 8475.

²⁰⁴⁷For an exception, see Meier, H.; Eckes, H.; Niedermann, H.; Kolshorn, H. *Angew. Chem. Int. Ed.* **1987**, *26*, 1046.

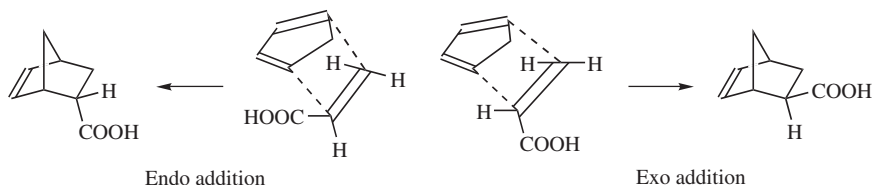

selectivity is predicted by disrotatory motion of the substituent in the transition state²⁰⁴⁸ of the reaction (see 18-27).

3. The diene must be in the cisoid conformation. If it is frozen into the transoid conformation, as in **198**, the reaction does not take place. The diene either must be frozen into the cisoid conformation or must be able to achieve it during the reaction.

198

4. When the diene is cyclic, there are two possible ways in which addition can occur if the dienophile is not symmetrical. The larger side of the dienophile may be under the ring (*endo addition*), or it may be the smaller side (*exo addition*):

Most of the time, the addition is predominantly *endo*; that is, the more bulky side of the alkene is under the ring, and this is probably true for open-chain dienes also.²⁰⁴⁹ However, exceptions are known, and in many cases mixtures of *exo* and *endo* addition products are found.²⁰⁵⁰ An imidazolidone catalyst was used to give a 1:1.3 mixture favoring the *exo* isomer in a reaction of conjugated aldehydes and cyclopentadiene.²⁰⁵¹ It has been argued that facial selectivity is not due to torsional angle decompression.²⁰⁵² Secondary orbital interactions.²⁰⁵³ have been invoked, but this approach has been called into question.²⁰⁵⁴ There has been a direct evaluation of such interactions, however.²⁰⁵⁵ The *endo/exo* ratio can be influenced by the nature of the solvent.²⁰⁵⁶

5. As we have seen, the Diels–Alder reaction can be both stereoselective and regioselective.²⁰⁵⁷ In some cases, the Diels–Alder reaction can be made enantioselective.²⁰⁵⁸ Solvent effects are important in such reactions.²⁰⁵⁹ The role of reactant polarity on the course of the reaction has been examined.²⁰⁶⁰ Most enantioselective Diels–Alder reactions have used a chiral dienophile (e.g., **199**) and an achiral diene,²⁰⁶¹ along with a Lewis acid catalyst (see below). In such cases, addition of the diene to the two faces²⁰⁶² of **199** takes place at different rates, and **200** and **201** are formed in different amounts.²⁰⁶³ An achiral compound A can be converted to a chiral compound by a chemical reaction with a compound B that is enantiopure. After the reaction, the resulting diastereomers can be separated, providing enantiopure compounds, each with a bond between molecule A and chiral compound B (a chiral auxiliary). Common chiral auxiliaries include chiral carboxylic acids, alcohols, or sultams. In the case illustrated, hydrolysis of the product removes the chiral R group, making it a chiral auxiliary in this reaction. Asymmetric Diels–Alder reactions have also been carried out with achiral dienes and dienophiles, but with an optically active catalyst.²⁰⁶⁴ Many chiral catalysts

have been developed.²⁰⁶⁵ In many cases, asymmetric Lewis acids form a chiral complex with the dienophile.²⁰⁶⁶

Many interesting compounds can be prepared by the Diels–Alder reaction,²⁰⁶⁷ some of which would be hard to make in any other way. Azelines react with dienes to form cyclohexene derivatives fused to a four-membered ring amine (azetidine).²⁰⁶⁸ The C₆₀-Fullerenes undergo Diels–Alder reactions,²⁰⁶⁹ and the reaction is reversible.²⁰⁷⁰ Bicyclic sultams can be prepared by an intramolecular Diels–Alder reaction.²⁰⁷¹ Polycyclic lactones can be prepared.²⁰⁷² Aromatic compounds can behave as dienes,²⁰⁷³ but benzene is very unreactive toward dienophiles,²⁰⁷⁴ and very few dienophiles (one of them is benzyne) have been reported to give Diels–Alder adducts with it.²⁰⁷⁵ Naphthalene and phenanthrene are also quite resistant, although naphthalene has given Diels–Alder addition at high pressures.²⁰⁷⁶ However, anthracene and other compounds with at least three linear benzene rings give Diels–Alder reactions readily. The interesting compound triptycene can be prepared by a Diels–Alder

reaction between benzyne and anthracene:²⁰⁷⁷ For both all-carbon and hetero systems, the “diene” can be a conjugated enyne. If the geometry of the molecule is suitable, the diene can even be nonconjugated, for example,²⁰⁷⁸

This last reaction is known as the *homo-Diels-Alder reaction*. A similar reaction has been reported with alkynes, using a mixture of a cobalt complex, ZnI_2 and tetrabutylammonium borohydride as catalysts.²⁰⁷⁹

Competing reactions are polymerization of the diene or dienophile, or both, and [1,2]-cycloaddition (**15-63**). Intramolecular versions of the Diels-Alder reaction are well-known, and this is a powerful method for the synthesis of mono- and polycyclic compounds.²⁰⁸⁰ There are many examples and variations. Internal Diels-Alder reactions can be viewed as linking the diene and alkene by a tether, usually of carbon atoms. If the tether is replaced by functional groups that allow the selectivity inherent to the intramolecular cycloaddition, but can be cleaved afterward, a powerful modification is available. Indeed, such tethered cycloaddition reactions are increasingly common. After cycloaddition, the tether can be cleaved to give a functionalized cyclohexene derivative. Such tethered reactions allow enhancement of stereoselectivity²⁰⁸¹ and sometimes reactivity, relative to an untethered reaction, giving an indirect method for enhancing those parameters. Tethers or linkages include $C-O-SiR_2-C$ ²⁰⁸² or a $C-O-SiR_2-O-C$,²⁰⁸³ or hydroxamides.²⁰⁸⁴ Transient tethers can be used, as in the reaction of a diene having an allylic alcohol unit in a reaction is allyl alcohol, with $AlMe_3$, to give the cycloadduct with good selectivity.²⁰⁸⁵

The Diels–Alder reaction is usually reversible, although the retro reaction typically occurs at significantly higher temperatures than the forward reaction. However, the reversibility of the reaction and has been used to protect double bonds.²⁰⁸⁶ A convenient substitute for butadiene in the Diels–Alder reaction is the compound 3-sulfolene since the latter is a solid which is easy to handle while the former is gas.²⁰⁸⁷ Butadiene is generated *in situ* by a reverse Diels–Alder reaction (see 17-20).

There are, broadly speaking, three possible mechanisms that have been considered for the uncatalyzed Diels–Alder reaction.²⁰⁸⁸ In mechanism *a* there is a cyclic six-centered transition state and no intermediate. The reaction is concerted and occurs in one step. In mechanism *b*, one end of the diene fastens to one end of the dienophile first to give a diradical, and then, in a second step, the other ends become fastened.²⁰⁸⁹ A diradical formed in this manner must be a singlet; that is, the two unpaired electrons must have opposite spins, by an argument similar to that outlined on p. 277. The third mechanism (*c*, not shown) is similar to mechanism *b*, but the initial bond and the subsequent bond are formed by movements of electron pairs and the intermediate is a diion. There have been many mechanistic investigations of the Diels–Alder reaction. The bulk of the evidence suggests that most Diels–Alder reactions take place by the one-step cyclic mechanism *a*,²⁰⁹⁰ although it is possible

that a diradical²⁰⁹¹ or even a diion²⁰⁹² mechanism may be taking place in some cases. Radical cation Diels–Alder reactions have been considered.²⁰⁹³ The main evidence in support of mechanism *a* is as follows: (1) The reaction is stereospecific in both the diene and dienophile. A completely free diradical or diion probably would not be able to retain its configuration. (2) In general, the rates of Diels–Alder reactions depend very little on the nature of the solvent. This would rule out a diion intermediate because polar solvents increase the rates of reactions that develop charges in the transition state. (3) It was shown that, in the decomposition of **202**, the isotope effect k_I/k_{II} was equal to 1.00 within experimental error.²⁰⁹⁴ If bond *x* were to break before bond *y*, there

should surely be a secondary isotope effect. This result strongly indicates that the bond breaking of *x* and *y* is simultaneous. This is the reverse of a Diels–Alder reaction, and by the principle of microscopic reversibility, the mechanism of the forward reaction should involve simultaneous formation of bonds *x* and *y*. Subsequently, a similar experiment was carried out on the forward reaction²⁰⁹⁵ and the result was the same. There is also other evidence for mechanism *a*.²⁰⁹⁶ However, the fact that the mechanism is concerted does not necessarily mean that it is synchronous.²⁰⁹⁷ In the transition state of a synchronous reaction both new σ bonds would be formed to the same extent, but a Diels–Alder reaction with non-symmetrical components might very well be non-synchronous;²⁰⁹⁸ that is, it could have a transition state in which one

bond has been formed to a greater degree than the other.²⁰⁹⁹ A biradical mechanism has been proposed for some Diels–Alder reactions.²¹⁰⁰

In another aspect of the mechanism, the effects of electron-donating and electron-withdrawing substituents (p. 1196) indicate that the diene is behaving as a nucleophile and the dienophile as an electrophile. However, this can be reversed. Perchlorocyclopentadiene reacts better with cyclopentene than with maleic anhydride and not at all with tetracyanoethylene, although the latter is normally the most reactive dienophile known. It is apparent, then, that this diene is the electrophile in its Diels–Alder reactions.²¹⁰¹ Reactions of this type are said to proceed with *inverse electron demand*.²¹⁰²

We have emphasized that the Diels–Alder reaction generally takes place rapidly and conveniently. In sharp contrast, the apparently similar dimerization of alkenes to cyclobutanes (**15-63**) gives very poor results in most cases, except when photochemically induced. Woodward and Hoffmann, and Fukui have shown that these contrasting results can be explained by the *principle of conservation of orbital symmetry*,²¹⁰³ which predicts that certain reactions are allowed and others forbidden. The orbital-symmetry rules (also called the Woodward–Hoffmann rules)²¹⁰⁴ apply *only to concerted reactions*, for example, mechanism *a*, and are based on the principle that reactions take place in such a way as to maintain maximum bonding throughout the course of the reaction. There are several ways of applying the orbital-symmetry principle to cycloaddition reactions, three

of which are used more frequently than others.²¹⁰⁵ Of these three, we will discuss two: the frontier-orbital method and the Möbius–Hückel method. The third, called the correlation diagram method,²¹⁰⁶ is less convenient to apply than the other two.

The Frontier Orbital Method²¹⁰⁷

As applied to cycloaddition reactions the rule is that *reactions are allowed only when all overlaps between the highest occupied molecular orbital (HOMO) of one reactant and the lowest unoccupied molecular orbital (LUMO) of the other are such that a positive lobe overlaps only with another positive lobe and a negative lobe only with another negative lobe*. We may recall that monoalkenes have two π molecular orbitals (p. 10) and that conjugated dienes have four (p. 38), as shown in Fig. 15.2. A concerted cyclization of two monoalkenes (a [2 + 2]-reaction) is not allowed because it would require that a positive lobe overlap with a negative lobe (Fig. 15.3). On the other hand, the Diels–Alder reaction (a [4 + 2]-reaction) is allowed, whether considered from either direction (Fig. 15.4).

These considerations are reversed when the ring closures are photochemically induced since in such cases an electron is promoted to a vacant orbital before the reaction occurs. Obviously, the [2 + 2] reaction is now allowed (Fig. 15.5) and the [4 + 2]-reaction disallowed. The reverse reactions follow the same rules, by the principle of microscopic reversibility. In fact, Diels–Alder adducts are usually cleaved quite readily, while cyclobutanes, despite the additional strain, require more strenuous conditions.

The Möbius–Hückel Method²¹⁰⁸

In this method, the orbital symmetry rules are related to the Hückel aromaticity rule discussed in Chapter 2.²¹⁰⁹ Hückel's rule, which states that a cyclic system of electrons is aromatic (hence, stable) when it consists of $4n + 2$ electrons, applies of course to molecules in their ground states. In applying the orbital symmetry principle we are not concerned with ground states, but with transition states. In the present method, we do not examine the molecular orbitals themselves, but rather the p orbitals before they overlap to form the molecular orbitals. Such a set of p orbitals is called a *basis set* (Fig. 15.6). In investigating the possibility of a concerted reaction, we put the basis sets into the position they would occupy in the transition state. Figure 15.7 shows this for both the $[2 + 2]$ and the $[4 + 2]$ ring closures. What we look for are *sign inversions*. In Fig. 15.7, we can see that there are no sign inversions in either case. That is, the dashed line connects only lobes with a minus sign. Systems with *zero or an even number* of sign inversions are called *Hückel systems*. Because they have no sign inversions, both of these systems are Hückel systems. Systems with *an odd number* of sign

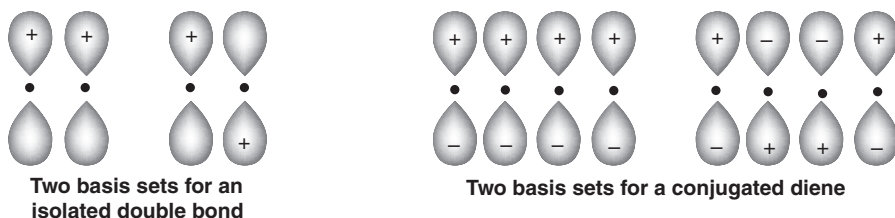

Fig. 15.6. Some basis sets.

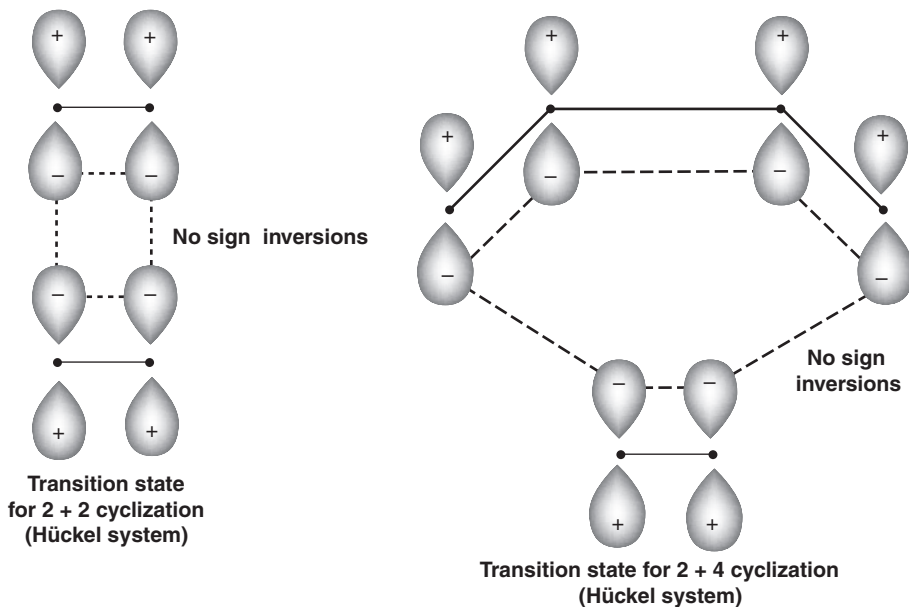

Fig. 15.7. Transition states illustrating Hückel–Möbius rules for cycloaddition reactions.

inversions are called *Möbius systems* (because of the similarity to the Möbius strip, which is a mathematical surface, shown in Fig. 15.8). Möbius systems do not enter into either of these reactions, but an example of such a system is shown on p. \$\$\$.

The rule may then be stated: *A thermal pericyclic reaction involving a Hückel system is allowed only if the total number of electrons is $4n + 2$. A thermal pericyclic reaction involving a Möbius system is allowed only if the total number of electrons is $4n$.* For photochemical reactions these rules are reversed. Since both the [4 + 2]- and [2 + 2]-cycloadditions are Hückel systems, the Möbius–Hückel method predicts that the [4 + 2]-reaction, with 6 electrons, is thermally allowed,

Fig. 15.8. A Möbius strip. Such a strip is easily constructed by twisting a thin strip of paper 180° and fastening the ends together.

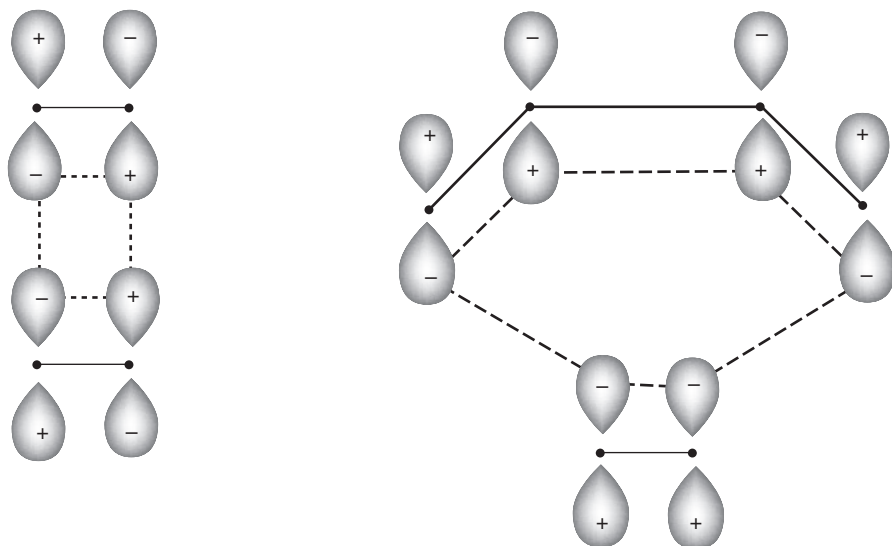

Fig. 15.9. Transition states of $[2 + 2]$ - and $[4 + 2]$ -cyclizations involving other basis sets.

but the $[2 + 2]$ -reaction is not. On the other hand, the $[2 + 2]$ -reaction is allowed photochemically, while the $[4 + 2]$ -reaction is forbidden.

Note that both the $[2 + 2]$ and $[4 + 2]$ transition states are Hückel systems no matter what basis sets we chose. For example, Fig. 15.9 shows other basis sets we might have chosen. In every case there will be zero or an even number of sign inversions.

Thus, the frontier orbital and Hückel–Möbius methods (and the correlation-diagram method as well) lead to the same conclusions: thermal $[4 + 2]$ -cycloadditions and photochemical $[2 + 2]$ -cycloadditions (and the reverse ring openings) are allowed, while photochemical $[4 + 2]$ and thermal $[2 + 2]$ ring closings (and openings) are forbidden.

Application of the same procedures to other ring closures shows that $[4 + 4]$ and $[2 + 6]$ ring closures and openings require photochemical induction while the $[4 + 6]$ - and $[2 + 8]$ -reactions can take place only thermally (see 15-53). In general, cycloaddition reactions allowed thermally are those with $4n + 2$ electrons, while those allowed photochemically have $4n$ electrons.

It must be emphasized once again that the rules apply only to cycloaddition reactions that take place by cyclic mechanisms, that is, where two σ bonds are formed (or broken) at about the same time.²¹¹⁰ The rule does not apply to cases where one bond is clearly formed (or broken) before the other. It must further be emphasized that the fact that the thermal Diels–Alder reaction (mechanism *a*) is allowed by the principle of conservation of orbital symmetry does not constitute

²¹¹⁰For a discussion of concertedness in these reactions see Lehr, R.E.; Marchand, A.P., in Marchand, A.P.; Lehr, R.E. *Pericyclic Reactions*, Vol. 1, Academic Press, NY, 1977, pp. 1–51.

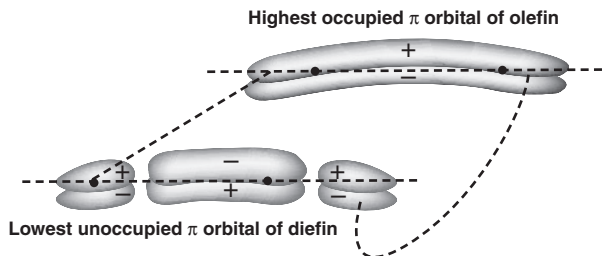

Fig. 15.10. Overlap of orbitals in an antarafacial thermal $[4 + 2]$ -cycloaddition.

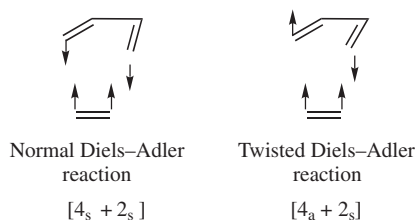

proof that any given Diels–Alder reaction proceeds by this mechanism. The principle merely says the mechanism is allowed, not that it must go by this pathway. However, the principle does say that thermal $[2 + 2]$ -cycloadditions in which the molecules assume a face-to-face geometry cannot²¹¹¹ take place by a cyclic mechanism because their activation energies would be too high (however, see below). As we will see (15-62), such reactions largely occur by two-step mechanisms. Similarly, $[4 + 2]$ -photochemical cycloadditions are also known, but the fact that they are not stereospecific indicates that they also take place by the two-step diradical mechanism (mechanism *b*).²¹¹²

In all of the above discussion we have assumed that a given molecule forms both the new σ bonds from the same face of the π system. This manner of bond formation, called *suprafacial*, is certainly most reasonable and almost always takes place. The subscript *s* is used to designate this geometry, and a normal Diels–Alder reaction would be called a $[\pi 2_s + \pi 4_s]$ -cycloaddition (the subscript π indicates that π electrons are involved in the cycloaddition). However, we can conceive of another approach in which the newly forming bonds of the diene lie on *opposite* faces of the π system, that is, they point in opposite directions. This type of orientation of the newly formed bonds is called *antarafacial*, and the reaction would be a $[\pi 2_s + \pi 4_a]$ -cycloaddition (a stands for antarafacial). We can easily show by the frontier-orbital method that this reaction (and consequently the reverse ring-opening reactions) are thermally forbidden and photochemically allowed. Thus in order for a $[\pi 2_s + \pi 4_a]$ -reaction to proceed, overlap between the highest occupied π orbital of the alkene and the lowest unoccupied π orbital of the diene would have to occur as shown in Fig. 15.10, with a + lobe

²¹¹¹The possibility has been raised that some disallowed reactions may nevertheless proceed by concerted mechanisms: see Schmidt, W. *Helv. Chim. Acta* **1971**, *54*, 862; *Tetrahedron Lett.* **1972**, 581; Muszkat, K.A.; Schmidt, W. *Helv. Chim. Acta* **1971**, *54*, 1195; Baldwin, J.E.; Andrist, A.H.; Pinschmidt Jr., R.K. *Acc. Chem. Res.* **1972**, *5*, 402; Berson, J.A. *Acc. Chem. Res.* **1972**, *5*, 406; Baldwin, J.E., in Marchand, A.P.; Lehr, R.E. *Pericyclic Reactions*, Vol. 2, Academic Press, NY, **1977**, pp. 273–302.

²¹¹²For example, see Sieber, W.; Heimgartner, H.; Hansen, H.; Schmid, H. *Helv. Chim. Acta* **1972**, *55*, 3005. For discussions see Bartlett, P.D.; Helgeson, R.; Wersel, O.A. *Pure Appl. Chem.* **1968**, *16*, 187; Seeley, D.A. *J. Am. Chem. Soc.* **1972**, *94*, 4378; Kaupp, G. *Angew. Chem. Int. Ed.* **1972**, *11*, 313, 718.

overlapping a $-$ lobe. Since like signs are no longer overlapping, the thermal reaction is now forbidden. Similarly, thermal $[\pi 4_s + \pi 2_a]$ - and

$[\pi 2_a + \pi 2_a]$ -cyclizations are forbidden, while thermal $[\pi 4_a + \pi 2_a]$ - and $[\pi 2_s + \pi 2_a]$ -cyclizations are allowed, and these considerations are reversed for the corresponding photochemical processes. Of course, an antarafacial approach is highly unlikely in a $[4 + 2]$ -cyclization,²¹¹³ but larger ring closures could take place by such a pathway, and $[2 + 2]$ -thermal cyclizations, where the $[\pi 2_s + \pi 2_s]$ pathway is forbidden, can also do so in certain cases (see **15-63**). We therefore see that whether a given cycloaddition is allowed or forbidden depends on the geometry of approach of the two molecules involved.

Symmetry considerations have also been advanced to explain predominant endo addition.²¹¹⁴ In the case of $[4 + 2]$ addition of butadiene to itself, the approach can be exo or endo. It can be seen (Fig. 15.11) that whether the HOMO of the diene overlaps with the LUMO of the alkene or vice versa, the endo orientation is stabilized by additional secondary overlap of orbitals²¹¹⁵ of like sign (dashed lines between heavy dots). Addition from the exo direction has no such stabilization. Evidence for secondary orbital overlap as the cause of predominant endo orientation, at least in some cases, is that $[4 + 6]$ -cycloaddition is predicted by similar considerations to proceed with predominant exo orientation, and that is what is found.²¹¹⁶ However, this explanation does not account for endo orientation in cases where the dienophile does not possess additional π orbitals, and a number of alternative explanations have been offered.²¹¹⁷

²¹¹³A possible photochemical $[\pi 2_a + \pi 4_s]$ -cycloaddition has been reported: Hart, H.; Miyashi, T.; Buchanan, D.N.; Sasson, S. *J. Am. Chem. Soc.* **1974**, *96*, 4857.

15-61 Heteroatom Diels–Alder Reactions

Carbon–carbon multiple bonds are not the only units that can participate in Diels–Alder reactions. Other double- and triple-bond compounds can be dienophiles and they give rise to heterocyclic compounds.²¹¹⁸ Among these are $\text{N}\equiv\text{C}-$, $-\text{N}=\text{C}-$,²¹¹⁹ iminium salts,²¹²⁰ $-\text{N}=\text{N}-$, $\text{O}=\text{N}-$,²¹²¹ and $-\text{C}=\text{O}$ compounds²¹²² and even molecular oxygen (**15-62**). It is noted that in the presence of a YbCl_3 catalyst, azirines reaction with dienes to give a 1-azabicyclo[4.1.0]heptene.²¹²³ Several catalysts can be used, depending on the nature of the heteroatoms incorporated into the alkene or diene.²¹²⁴ Intramolecular cycloaddition with a diene–imine substrate leads to pyrrolidines.²¹²⁵

Aldehydes react with suitably functionalized dienes, such as **203**, known as *Danishefsky's diene*,²¹²⁶ and the reaction usually requires a Lewis acid catalyst

such as lanthanide compounds. Aldehydes react using a chiral titanium²¹²⁷ or a zirconium²¹²⁸ catalyst to give the dihydropyran with good enantioselectivity. Note that the reaction of Danishefsky's diene with an imine, formed *in situ* by reaction of an aryl aldehyde and an aniline derivative, proceeds without a Lewis acid.²¹²⁹ Such reactions of aldehydes can be catalyzed with Lewis acids and transition-metal catalysts. The Diels–Alder reaction of aldehydes with dienes can be catalyzed by many transition-metal compounds, including cobalt²¹³⁰ and indium²¹³¹ catalyst. Ketones also react with suitably functionalized dienes.²¹³²

Azadienes undergo Diels–Alder reactions to form pyridine, dihydro- and tetrahydropyridine derivatives.²¹³³ Aza-Diels–Alder reactions have been done in ionic liquids.²¹³⁴ Similarly, acyl iminium salts $C=N(R)-C=O$ react with alkenes via cycloaddition.²¹³⁵ *N*-Vinyl lactim ethers undergo Diels–Alder reactions with a limited set of dienophiles.²¹³⁶ Thioketones react with dienes to give Diels–Alder cycloadducts.²¹³⁷ The carbonyl group of lactams have also been shown to be a dienophile.²¹³⁸ Certain heterocyclic aromatic rings (among them furans)²¹³⁹ can also behave as dienes in the Diels–Alder reaction. Some hetero dienes that give the reaction are $-C=C-C=O$, $O=C-C=O$, and $N=C-C=N$.¹⁹⁹⁹ Nitroso compounds of the type *t*-BuO₂C–N=O react with dienes to give the corresponding 2-azadihydropyran.²¹⁴⁰

Catalysts, such as $Fe(BuEtCHCO_2)_3$, have been developed that are effective for the heteroatom Diels–Alder reaction.²¹⁴¹ Indium trichloride ($InCl_3$) is a good catalyst for imino-Diels–Alder reactions.²¹⁴² Hetero-Diels–Alder reactions involving carbonyls have been done in water.²¹⁴³ Ultrasound has been used to promote the Diels–Alder reactions of 1-azadienes.²¹⁴⁴ Polymer-supported dienes have been used.²¹⁴⁵

Hetero- Diels–Alder reactions that proceed with good to excellent asymmetric induction are well known.²¹⁴⁶ Chiral 1-aza-dienes have been developed as substrates, for example.²¹⁴⁷ Chiral catalysts have been developed.²¹⁴⁸ Conjugated aldehydes react with vinyl ethers, with a chiral chromium catalyst, in an inverse electron demand cycloaddition that give a dihydropyran with good enantioselectivity.²¹⁴⁹ Vinyl sulfilimines have been used in chiral Diels–Alder reactions.²¹⁵⁰

15-62 Photooxidation of Dienes (Addition of Oxygen, Oxygen)

[4 + 2] *OC,OC-cyclo-Peroxy-1/4*/addition

Conjugated dienes react with oxygen under the influence of light to give cyclic peroxides **204**.²¹⁵¹ The reaction has mostly²¹⁵² been applied to cyclic dienes.²¹⁵³ Cycloaddition of furan has been reported using singlet oxygen.²¹⁵⁴ The scope extends to certain aromatic compounds such as phenanthrene.²¹⁵⁵ Besides those dienes and aromatic rings that can be photooxidized directly, there is a larger group that give the reaction in the presence of a photosensitizer such as eosin (see p. 340).

Among these is α -terpinene, which is converted to ascaridole:

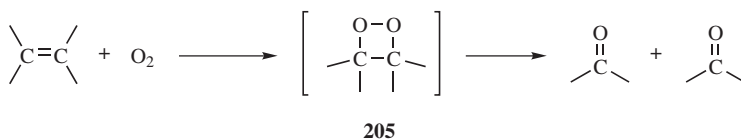

As in **14-7**, it is not the ground-state oxygen (the triplet), that reacts, but the excited singlet state,^{2156,2157} so the reaction is actually a Diels–Alder reaction (see **15-60**) with singlet oxygen as dienophile.²¹⁵⁸

Like **15-60**, this reaction is reversible.

We have previously discussed the reaction of singlet oxygen with double-bond compounds to give

hydroperoxides (**14-7**), but singlet oxygen can also react with double bonds in another way to give a dioxetane intermediate²¹⁵⁹ (**205**), which usually cleaves to

aldehydes or ketones,²¹⁶⁰ but has been isolated.²¹⁶¹ Both the six-membered cyclic peroxides²¹⁶² and the four-membered **205**²¹⁶³ have been formed from oxygenation reactions that do not involve singlet oxygen. If cyclic peroxides, such as **205**, are desired, better reagents²¹⁶⁴ are triphenyl phosphite ozonide (PhO)₃PO₃ and triethylsilyl hydrotrioxide (Et₃SiOOH), but yields are not high.²¹⁶⁵

15-63 [2 + 2]-Cycloadditions

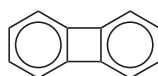

[2 + 2]cyclo-Ethylene-1/2/addition

The thermal reaction between two molecules of alkene to give cyclobutane derivatives (a [2 + 2]-cycloaddition) can be carried out where the alkenes are the same or different, but the reaction is not a general one for alkenes.²¹⁶⁶ The cycloaddition can be catalyzed by certain transition-metal complexes.²¹⁶⁷ Dimerization of like alkenes occurs with the following compounds: F₂C=CX₂ (X = F or Cl) and certain other

206

Biphenylene

For a list of references, see Larock, R.C. *Comprehensive Organic Transformations*, 2nd ed., Wiley-VCH, NY, **1999**, pp. 546–647, 1341–1344.

²¹⁶⁷For an example using EtAlCl₂ see Takasu, K.; Ueno, M.; Inanaga, K.; Ihara, M. *J. Org. Chem.* **2004**, *69*, 517.

fluorinated alkenes (although not $F_2C=CH_2$), allenes (to give derivatives of **206**),²¹⁶⁸ benzyne (to give biphenylene derivatives),²¹⁶⁹ activated alkenes (e.g., styrene, acrylonitrile, butadiene), and certain methylenecyclopropanes.²¹⁷⁰ Dimerization of allenes lead to bis(alkylidene) cyclobutanes.²¹⁷¹ Substituted ketenes can dimerize to give cyclobutenone derivatives, although ketene itself dimerizes in a different manner, to give an unsaturated β -lactone (**16-95**).²¹⁷² Alkenes react with activated alkynes, with a ruthenium catalyst, to give cyclobutenes.²¹⁷³

Intramolecular $[2 + 2]$ -cycloadditions are common in which a diene is converted to a bicyclic compound with a four-membered ring fused to another ring. Heating *N*-vinyl imines, where the vinyl moiety is a silyl enol, gives β -lactams.²¹⁷⁴ Apart from photochemical initiation of such reactions, intramolecular cycloaddition of two conjugated ketone units, in the presence of $PhMeSiH_2$ and catalyzed by cobalt compounds, leads to the bicyclic compound with two ketone substituents.²¹⁷⁵ In a variation of this reaction, a diyne was treated with $Ti(OiPr)_4/2$ *i*-PrMgCl to generate a bicyclic cyclobutene with two vinylidene units.²¹⁷⁶

Ketenes react with many alkenes to give cyclobutanone derivatives²¹⁷⁷ and intermolecular cycloadditions are well known.²¹⁷⁸ typical reaction is that of dimethylketene and ethene to give 2,2-dimethylcyclobutanone.²¹⁷⁹ Ketenes react with imines via $[2 + 2]$ -cycloaddition to produce β -lactams.²¹⁸⁰ Cycloaddition of an imine with a conjugated ester in the presence of Et_2MeSiH and an iridium

catalyst also gives a β -lactam.²¹⁸¹

Different alkenes combine as follows:

1. $\text{F}_2\text{C}=\text{CX}_2$ (X = F or Cl), especially $\text{F}_2\text{C}=\text{CF}_2$, form cyclobutanes with many alkenes. Compounds of this type even react with conjugated dienes to give four-membered rings rather than undergoing normal Diels–Alder reactions.²¹⁸²
2. Allenes²¹⁸³ and ketenes²¹⁸⁴ react with activated alkenes and alkynes. Ketenes give 1,2-addition, even with conjugated dienes.²¹⁸⁵ Ketenes also add to unactivated alkenes if sufficiently long reaction times are used.²¹⁸⁶ Allenes and ketenes also add to each other.²¹⁸⁷
3. Enamines²¹⁸⁸ form four-membered rings with Michael-type alkenes²¹⁸⁹ and ketenes.²¹⁹⁰ In both cases, only enamines from aldehydes give stable

four-membered rings:

The reaction of enamines with ketenes can be conveniently carried out by generating the ketene *in situ* from an acyl halide and a tertiary amine.

4. Alkenes with electron-withdrawing groups may form cyclobutanes with alkenes containing electron-donating groups. The enamine reactions, mentioned above, are examples of this, but it has also been accomplished with tetracyanoethylene and similar molecules, which give substituted cyclobutanes when treated with alkenes of the form $\text{C}=\text{C}-\text{A}$, where A may be OR,²¹⁹¹ SR (enol and thioenol ethers),²¹⁹² cyclopropyl,²¹⁹³ or certain aryl groups.²¹⁹⁴

Solvents are not necessary for [2 + 2]-cycloadditions. They are usually carried out at 100–225°C under pressure, although the reactions in Group 4 (IVB) occur under milder conditions.

It has been found that certain [2 + 2]-cycloadditions, which do not occur thermally can be made to take place without photochemical initiation by the use of certain catalysts, usually transition-metal compounds.²¹⁹⁵ Photochemical²¹⁹⁶ [$\pi 2 + s 2$]-cycloadditions have also been reported. Among the catalysts used are Lewis acids²¹⁹⁷ and phosphine–nickel complexes.²¹⁹⁸ Certain of the reverse cyclobutane ring openings can also be catalytically induced (18-38). The role of the catalyst is not certain and may be different in each case. One possibility is that the

presence of the catalyst causes a forbidden reaction to become allowed, through coordination of the catalyst to the π or s bonds of the substrate.²¹⁹⁹ In such a case, the reaction would of course be a concerted $[2_s + 2_s]$ -process.²²⁰⁰ However, the available evidence is more consistent with nonconcerted mechanisms involving metal–carbon σ -bonded intermediates, at least in most cases.²²⁰¹ For example, such an intermediate was isolated in the dimerization of norbornadiene, catalyzed by iridium complexes.²²⁰²

Thermal cycloadditions leading to four-membered rings can also take place between a cyclopropane ring and an alkene or alkyne²²⁰³ bearing electron-withdrawing groups.²²⁰⁴ These reactions are $[\pi 2 + s 2]$ -cycloadditions. Ordinary cyclopropanes do not undergo the reaction, but it has been accomplished with strained systems such as bicyclo[1.1.0]butanes²²⁰⁵ and bicyclo[2.1.0]pentanes. For example, bicyclo[2.1.0]pentane reacts with maleonitrile (or fumaronitrile) to give all three isomers of 2,3-dicyanonorbornane, as well as four other products.²²⁰⁶ The lack of stereospecificity and the negligible effect of solvent on the rate indicate a diradical mechanism.

The reaction is similar to the Diels–Alder (in action, not in scope), and if dienes are involved, the latter reaction may compete, although most alkenes react with a diene either entirely by 1,2 or entirely by 1,4 addition. Three mechanisms can be proposed²²⁰⁷ analogous to those proposed for the Diels–Alder reaction. Mechanism *a* is a

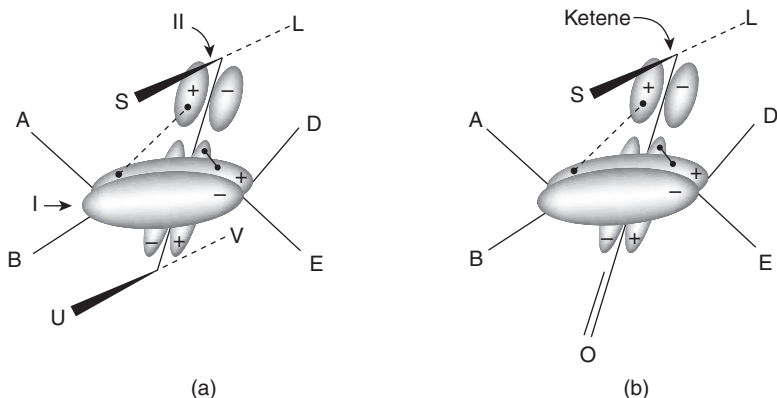

Fig. 15.12. Orbital overlap in $[\pi 2_s + \pi 2_s]$ -cycloaddition between (a) two alkene molecules and (b) a ketene and an alkene. S and L stand for small and large

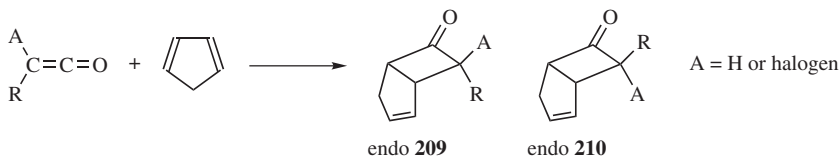

concerted pericyclic process, and mechanisms *b* and *c* are two-step reactions involving, respectively, a diradical (**207**) and a diion (**208**) intermediate. As in **15-60**, a diradical intermediate must be a singlet. In searching for ways to tell which mechanism is operating in a given case, we would expect mechanism *c* to be sensitive to changes in solvent polarity, while mechanisms *a* and *b* should be insensitive. We would also expect mechanism *a* to be stereospecific, while mechanisms *b* and *c* probably would not be stereospecific, although if the second step of these processes takes place very rapidly, before **207** or **208** has a chance to rotate about the newly formed single bond, stereospecificity might be observed. Because of entropy considerations such rapid ring closure might be more likely here than in a $[4 + 2]$ -cycloaddition.

There is evidence that the reactions can take place by all three mechanisms, depending on the structure of the reactants. A thermal $[\pi 2_s + \pi 2_s]$ mechanism is ruled out for most of these substrates by the orbital symmetry rules, but a $[\pi 2_s + \pi 2_a]$ mechanism is allowed (p. 1212), and there is much evidence that ketenes and certain other linear molecules²²⁰⁸ in which the steric hindrance to such an approach is minimal can and often do react by this mechanism. In a $[\pi 2_s + \pi 2_a]$ -cycloaddition the molecules must approach each other in such a way (Fig. 15.12*a*) that the + lobe of the HOMO of one molecule (I) overlaps with both + lobes of the LUMO of the other (II), even although these lobes are on opposite sides of the nodal plane of II. The geometry of this approach requires that the groups S and U of molecule II project *into* the plane of molecule I. This has not been found to happen for ordinary alkenes,²²⁰⁹ but if

²²⁰⁸There is evidence that a cyclopentene (generated *in situ*) also adds to a double bond by an antarafacial process: Gilbert, J.C.; Baze, M.E. *J. Am. Chem. Soc.* **1984**, *106*, 1885.

²²⁰⁹See, for example, Padwa, A.; Koehn, W.; Masaracchia, J.; Osborn, C.L.; Trecker, D.J. *J. Am. Chem. Soc.* **1971**, *93*, 3633; Bartlett, P.D.; Cohen, G.M.; Elliott, S.P.; Hummel, K.; Minns, R.A.; Sharts, C.M.; Fukunaga, J.Y. *J. Am. Chem. Soc.* **1972**, *94*, 2899.

molecule **II** is a ketene (Fig. 15.12*b*), the group marked U is not present and the $[\pi 2_s + \pi 2_a]$ -reaction can take place. Among the evidence²²¹⁰ for this mechanism²²¹¹ is the following: (1) The reactions are stereospecific.²²¹² (2) The isomer that forms is the *more-hindered one*. Thus methylketene plus cyclopentadiene gave only the endo product (**209**, A = H, R = CH₃).²²¹³ Even more remarkably, when

haloalkyl ketenes $RXC=C=O$ were treated with cyclopentadiene, the endo/exo ratio of the product (**209**, **210**, A = halogen) actually *increased* substantially when R was changed from Me to *i*-Pr to *t*-Bu!²²¹⁴ One would expect preferential formation of the exo products (**210**) from $[\pi 2_s + \pi 2_s]$ -cycloadditions where the molecules approach each other face-to-face, but a $[\pi 2_s + \pi 2_a]$ process leads to endo products because the ketene molecule (which for steric reasons would approach with its smaller group directed toward the alkene) must twist as shown in Fig. 15.13 (L = larger; S = smaller group) in order for the + lobes to interact and this swings the larger group into the endo position.²²¹⁵ The experimental results in which the amount of endo isomer increases with the increasing size of the R group would seem to be contrary to what would be expected from

²²¹⁰For other evidence, see Baldwin, J.E.; Kapecki, J.A. *J. Am. Chem. Soc.* **1970**, *92*, 4874; Brook, P.R.; Griffiths, J.G. *Chem. Commun.* **1970**, 1344; Egger, K.W. *Int. J. Chem. Fig. 15.13. Orbital overlap in the reaction of a ketene with cyclopentadiene. S and L stand for small and large.

considerations of steric hindrance (we may call them *masochistic steric effects*), but they are just what is predicted for a $[\pi 2_s + \pi 2_a]$ -reaction. (3) There is only moderate polar solvent acceleration.²²¹⁶ (4) The rate of the reaction is not very sensitive to the presence of electron-withdrawing or electron-donating substituents.²²¹⁷ Because cycloadditions involving allenes are often stereospecific, it has been suggested that these also take place by the $[\pi 2_s + \pi 2_a]$ mechanism,²²¹⁸ but the evidence in these cases is more consistent with the diradical mechanism *b*.²²¹⁹

The diradical mechanism *b* is most prominent in the reactions involving fluorinated alkenes.²²²⁰ These reactions are generally not stereospecific²²²¹ and are insensitive to solvent effects. Further evidence that a diion is not involved is that head-to-head coupling is found when an unsymmetrical molecule is dimerized. Thus dimerization of $F_2C=CFCl$ gives **211**, not **212**. If one pair of electrons moved before the other, the positive end of one molecule would be expected to attack the

Chem.* **1990**, *55*, 711; Becker, D.; Denekamp, C.; Haddad, N. *Tetrahedron Lett.* **1992**, *33*, 827.

²²²⁰It has been argued that the mechanism here is not the diradical mechanism, but the $[\pi 2_s + \pi 2_a]$ mechanism: Roberts, D.W. *Tetrahedron* **1985**, *41*, 5529.

²²²¹Bartlett, P.D.; Hummel, K.; Elliott, S.P.; Minns, R.A. *J. Am. Chem. Soc.* **1972**, *94*, 2898.

negative end of the other.²²²²

The diion mechanism²²²³ *c* has been reported for at least some of the reactions²²²⁴ in categories 3 and 4,²²²⁵ as well as some ketene dimerizations.²²²⁶ For example, the rate of the reaction between 1,2-bis(trifluoromethyl)-1,2-dicyanoethene and ethyl vinyl ether was strongly influenced by changes in solvent polarity.²²²⁷ Some of these reactions are nonstereospecific, but others are stereospecific.²²²⁸ As previously indicated, it is likely that in the latter cases the diionic intermediate closes before rotation can take place. Such rapid ring closure is more likely for a diion than for a diradical because of the attraction between the opposite charges. Other evidence for the diion mechanism in these cases is that reaction rates are greatly dependent on the presence of electron-donating and electron-withdrawing groups and that it is possible to trap the diionic intermediates.

Whether a given alkene reacts by the diradical or diion mechanism depends, among other things, on the groups attached to it. For example, phenyl and vinyl groups at the α positions of **207** or **208** help to stabilize a diradical, while donors, such as oxygen and nitrogen, favor a diion (they stabilize the positively charged end).²²²⁹ A table on p. 451 of Ref. 2230 shows which mechanism is more likely for [2 + 2]-cycloadditions of various pairs of alkenes.

Thermal cleavage of cyclobutanes²²³⁰ to give two alkene molecules (*cycloreversion*,²²³¹ the reverse of [2 + 2]-cycloaddition) operates by the diradical mechanism,

and the $[\sigma 2_s + \sigma 2_a]$ pathway has not been found²²³² (the subscripts σ indicate that σ bonds are involved in this reaction).

In some cases, double bonds add to triple bonds to give cyclobutenes, apparently at about the same rate that they add to double bonds. The addition of triple bonds to triple bonds would give cyclobutadienes, and this has not been observed, except where these rearrange before they can be isolated (see **15-65**)²²³³ or in the presence of a suitable coordination compound, so that the cyclobutadiene is produced in the form of a complex (p. 76).²²³⁴

Although thermal $[2 + 2]$ -cycloaddition reactions are essentially limited to the cases described above, many (although by no means all) double-bond compounds undergo such reactions *when photochemically excited* (either directly or by a photosensitizer, see p. 340), even if they are not in the above categories.²²³⁵ Simple alkenes absorb in the far UV (p. 332), which is difficult to reach experimentally, although this problem can sometimes be overcome by the use of suitable photosensitizers. The reaction has been applied to simple alkenes²²³⁶ (especially to strained compounds, such as cyclopropenes and cyclobutenes), but more often the double-bond compounds involved are conjugated dienes,²²³⁷ α,β -unsaturated ketones,²²³⁸

obtained instead of the desired product.

The photochemical cycloaddition of a carbonyl, generally from an aldehyde or ketone, and an alkene is called the *Paternò-Büchi reaction*.²²⁴⁴ This [2 + 2]-cycloaddition gives an oxetane (**213**) and the reaction is believed to proceed via a diradical intermediate. Silyl enol ethers react with aldehydes under nonphotochemical conditions using ZnCl_2 at 25°C or SnCl_4 at -78°C .²²⁴⁵

It is possible that some of these photochemical cycloadditions take place by a $[\pi 2_s + \pi 2_s]$ mechanism (which is of course allowed by orbital symmetry); when and if they do, one of the molecules must be in the excited singlet state (S_1) and the other in the ground state.²²⁴⁶ The nonphotosensitized dimerizations of *cis*- and *trans*-2-butene are stereospecific,²²⁴⁷ making it likely that the $[\pi 2_s + \pi 2_s]$ mechanism is operating in these reactions. However, in most cases it is a triplet excited state that reacts with the ground-state molecule; in these cases the diradical (or in certain cases, the diionic) mechanism is taking place.²²⁴⁸ In one intramolecular case, the intermediate diradical has been trapped.²²⁴⁹ Photosensitized $[2\pi + 2\pi]$ -cycloadditions almost always involve the triplet state, and hence a diradical (or diionic) mechanism.

The photochemical diradical mechanism is not quite the same as the thermal diradical mechanism. In the thermal mechanism the initially formed diradical must be a singlet, but in the photochemical process a triplet excited state is adding to a ground state (which is of course a singlet). Thus, in order to conserve spin,²²⁵⁰ the initially formed diradical must be a triplet; that is, the two electrons must have the same spin. Consequently, the second, or ring-closing, step of the mechanism cannot take place at once, because a new bond cannot form from a combination of two electrons with the same spin, and the diradical has a reasonably long lifetime before collisions with molecules in the environment allow a spin inversion to take

²²⁵⁰This is an example of the Wigner spin conservation rule (p. 340). Note that spin conservation is something entirely different from symmetry conservation.

place and the diradical to cyclize. We would therefore predict nonstereospecificity, and that is what is found.²²⁵¹ It has been believed that at least some $[2 + 2]$ -photocycloadditions take place by way of exciplex intermediates²²⁵² [an *exciplex*²²⁵³ is an excited EDA complex (p. 342) that is dissociated in the ground state; in this case one double bond is the donor and the other the acceptor], but there is evidence against this.²²⁵⁴

In **15-60**, we used the principle of conservation of orbital symmetry to explain why certain reactions take place readily and others do not. The orbital-symmetry principle can also explain why certain molecules are stable although highly strained. For example, quadricyclane and hexamethylprismane²²⁵⁵ are thermodynamically much less stable (because much more strained) than their corresponding isomeric dienes, norbornadiene and

hexamethylbicyclo[2.2.0]hexadiene (**214**).²²⁵⁶ Yet the former two compounds can be kept indefinitely at room temperature, although in the absence of orbital-symmetry considerations it is not easy to understand why the electrons simply do not move over to give the more stable diene isomers. The reason is that both these reactions involve the conversion of a cyclobutane ring to a pair of double bonds (a $s_2 + s_2$ process) and, as we have seen, a thermal process of this sort is forbidden by the Woodward–Hoffmann rules. The process is allowed photochemically, and we are not surprised to find that both quadricyclane and hexamethylprismane are photochemically converted to the respective dienes at room temperature or below.²²⁵⁷ It is also possible to conceive of simple

²²⁵¹See, for example, Liu, R.S.H.; Hammond, G.S. *J. Am. Chem. Soc.* **1967**, *89*, 4936; Kramer, B.D.; Bartlett, P.D. *J. Am. Chem. Soc.* **1972**, *94*, 3934.

²²⁵⁵This compound can be prepared by photolysis of **210**, another example of an intramolecular photochemical $[2 + 2]$ -cycloaddition: Lemal, D.M.; Lokensgard, J.P. *J. Am. Chem. Soc.* **1966**, *88*, 5934; Schäfer, W.; Criegee, R.; Askani, R.; Grüner, H. *Angew. Chem. Int. Ed.* **1967**, *6*, 78.

²²⁵⁶For a review of this compound, see Schäfer, W.; Hellmann, H. *Angew. Chem. Int. Ed.* **1967**, *6*, 518.

²²⁵⁷These conversions can also be carried out by the use of transition-metal catalysts: Hogeveen, H.; Volger, H.C. *Chem. Commun.* **1967**, 1133; *J. Am. Chem. Soc.* **1967**, *89*, 2486; Kaiser, K.L.; Childs, R.F.; Maitlis, P.M. *J. Am. Chem. Soc.* **1971**, *93*, 1270; Landis, M.E.; Gremaud, D.; Patrick, T.B. *Tetrahedron Lett.* **1982**, *23*, 375; Maruyama, K.; Tamiaki, H. *Chem. Lett.* **1987**, 683.

bond rearrangements whereby hexamethylprismane is converted to hexamethylbenzene, which

of course is far more stable than either hexamethylprismane or **214**. It has been calculated that hexamethylbenzene is at least 90 kcal mol^{-1} (380 kJ mol^{-1}) more stable than hexamethylprismane. The fact that hexamethylprismane does not spontaneously undergo this reaction has prompted the observation²²⁵⁸ that the prismane has “the aspect of an angry tiger unable to break out of a paper cage.” However, a correlation diagram for this reaction²²⁵⁹ discloses that it too is a symmetry-forbidden process. All three of these “forbidden” reactions do take place when the compounds are heated, but the diradical mechanism is likely under these conditions.²²⁵⁹

Bicyclo[2.2.0]hexadienes and prismanes are *valence isomers* of benzenes.²²⁶⁰ These compounds actually have the structures that were proposed for benzenes in the nineteenth century. Prismanes have the Ladenburg formula, and bicyclo[2.2.0]hexadienes have the Dewar formula. Because of this bicyclo[2.2.0]hexadiene is often called Dewar benzene. On p. 32, it was mentioned that Dewar formulas are canonical forms (although not very important) of benzenes. Yet they also exist as separate compounds in which the positions of the nuclei are different from those of benzenes.

Carbenes and substituted carbenes add to double bonds to give cyclopropane derivatives by what can be considered as a formal [1 + 2]-cycloaddition.²²⁶¹ Many carbene derivatives, for example, PhCH, ROCH,²²⁶² Me₂C=C, C(CN)₂, have been added to double bonds, but the reaction is often performed with CH₂ itself, with halo and dihalocarbenes,²²⁶³ and with carbalkoxycarbenes²²⁶⁴ (generated from diazoacetic esters). Alkylcarbenes HCR have been added to alkenes,²²⁶⁵ but more often these rearrange to give alkenes (p. 291). The carbene can be generated in any of the ways normally used (p. 287). However, most reactions in which a cyclopropane is formed by treatment of an alkene with a carbene “precursor” do not actually involve free carbene intermediates. In some cases, it is certain that free carbenes are not involved, and in other cases there is doubt. Because of this, the term *carbene transfer* is often used to cover all reactions in which a double bond is converted to a cyclopropane, whether a carbene or a carbenoid (p. 288) is actually involved.

Carbene itself (:CH₂) is extremely reactive and gives many side reactions, especially insertion reactions (12-21), which greatly reduce yields. This competition is also true with rhodium-catalyzed diazoalkane cyclopropanations²²⁶⁶ (see below). When it is desired to add :CH₂ for preparative purposes, free carbene is not used, but the Simmons-Smith procedure (p. 1241) or some other method that does not involve free carbenes is employed instead. Halocarbenes are less active than carbenes, and this reaction proceeds quite well, since insertion reactions do not interfere.²²⁶⁷ The absolute rate constant for addition of selected alkoxychlorocarbene to butenes has been measured to range from 330 to $1 \times 10^4 M^{-1} s^{-1}$.²²⁶⁸ A few of the many ways²²⁶⁹ in which halocarbenes or carbenoids are generated for

²²⁶⁹Much of the work in this field has been carried out by Seyferth, D. and co-workers; see, for example, Seyferth, D.; Haas, C.K. *J. Org. Chem.* 1975, 40, 1620; Seyferth, D.; Haas, C.K.; Dagani, D. *J. Organomet. Chem.* 1976, 104, 9.

this reaction are the following,²²⁷⁰ most of which involve formal elimination (the first two steps of the S_N1cB mechanism, p. 521):

The reaction between CHCl₃ and HO⁻ is often carried out under phase transfer conditions.²²⁷⁴ It has been shown that the reaction between PhCHCl₂ and *t*-BuOK produces a carbenoid, but when the reaction is run in the presence of a crown ether, the free Ph(Cl)C: is formed instead.²²⁷⁵ The reaction of iodoform and CrCl₂ leads to iodocyclopropanes upon reaction with alkenes.²²⁷⁶ Dihalocyclopropanes are very useful compounds²²⁷⁷ that can be reduced to cyclopropanes, treated with magnesium or sodium to give allenes (**18-3**), or converted to a number of other products.

Alkenes of all types can be converted to cyclopropane derivatives by this reaction, but difficulty may be encountered with sterically hindered ones.²²⁷⁸

most important. Chromium complexes have been used for the cyclopropanation of alkenes.²²⁸⁹

Polymer-supported benzenesulfonyl azides have been developed as a safe diazo-transfer reagent.²²⁹⁰ These compounds, including CH_2N_2 and other diazoalkanes, react with metals or metal salts (copper, palladium,²²⁹¹ and rhodium are most commonly used) to give the carbene complexes that add: CRR' to double bonds.²²⁹² Diazoketones and diazoesters with alkenes to give the cyclopropane derivative, usually with a transition-metal catalyst, such as a copper complex.²²⁹³ The ruthenium catalyst reaction of diazoesters with an alkyne give a cyclopropene.²²⁹⁴ An X-ray structure of an osmium catalyst intermediate has been determined.²²⁹⁵ Electron-rich alkenes react faster than simple alkenes.²²⁹⁶

Optically active complexes have been used for enantioselective cyclopropane synthesis.²²⁹⁷ Decomposition of diazoalkanes in the presence of chiral rhodium²²⁹⁸ copper,²²⁹⁹ or ruthenium²³⁰⁰ complexes leads to optically active cyclopropanes.

The use of chiral additives with a rhodium complex also leads to cyclopropanes enantioselectively.²³⁰¹ An important chiral rhodium species is $\text{Rh}_2(\text{S-DOSP})_4$,²³⁰² which leads to cyclopropanes with excellent enantioselectivity in carbene cyclopropanation reactions.²³⁰³ Asymmetric, intramolecular cyclopropanation reactions have been reported.²³⁰⁴ The copper catalyzed diazoester cyclopropanation was reported in an ionic liquid.²³⁰⁵ It is noted that the reaction of a diazoester with a chiral dirhodium catalyst leads to β -lactones with modest enantioselectivity.²³⁰⁶ Phosphonate esters have been incorporated into the diazo compound.²³⁰⁷

Triple-bond compounds²³⁰⁸ react with carbenes to give cyclopropenes, except that in the case of acetylene itself, the cyclopropenes first formed cannot be isolated because they rearrange to allenes.²³⁰⁹ Cyclopropenones (p. 73) are obtained by hydrolysis of dihalocyclopropenes.²³¹⁰

Most carbenes are electrophilic, and, in accord with this, electron-donating substituents on the alkene increase the rate of the reaction, and electron-withdrawing groups decrease it,²³¹¹ although the range of relative rates is not very great.²³¹² As discussed on p. 284, carbenes in the singlet state (which is the most common state) react stereospecifically and syn,²³¹³ probably by a one-step mechanism,²³¹⁴ similar

to mechanism *a* of **15-60** and **15-63**:

Infrared spectra of a carbene and the cyclopropane product have been observed in an argon matrix at 12–45 K.²³¹⁵ Carbenes in the triplet state react nonstereospecifically,²³¹⁶ probably by a diradical mechanism, similar to mechanism *b* of **15-49** and **15-63**:

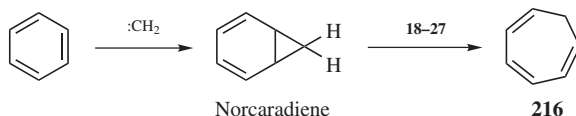

For carbenes or carbenoids of the type R–C–R' there is another aspect of stereochemistry.²³¹⁷ When these species are added to all but symmetrical alkenes, two isomers are possible, even if the four groups originally on the double-bond carbons maintain their configurations:

Which isomer is predominantly formed depends on R, R', and on the method by which the carbene or carbenoid is generated. Most studies have been carried out on monosubstituted species (R' = H), and in these studies it is found that aryl groups generally prefer the more substituted side (syn addition) while carboethoxy groups usually show anti stereoselectivity. When R = halogen, free halocarbenes show little or no stereochemical preference, while halocarbenoids exhibit a preference for syn addition. Beyond this, it is difficult to make simple generalizations.

Carbenes are so reactive that they add to the “double bonds” of aromatic rings.²³¹⁸ The products are usually unstable and rearrange to give ring expansion. Carbene reacts with benzene to give cycloheptatriene (**216**),²³¹⁹

but not all carbenes are reactive enough to add to benzene. The norcaradiene intermediate cannot be isolated in this case²³²⁰ (it undergoes an electrocyclic rearrangement, **18-27**), although certain substituted norcaradienes, for example, the product of addition of: $C(CN)_2$ to benzene,²³²¹ have been isolated.²³²² With: CH_2 , insertion is a major side reaction, and, for example, benzene gives toluene as well as cycloheptatriene. A method of adding: CH_2 to benzene rings without the use of free carbene is the catalytic decomposition of diazomethane (CH_2N_2) in the aromatic compound as solvent with $CuCl$ or $CuBr$.²³²³ By this method better yields of cycloheptatrienes are obtained without insertion side products. Picosecond optical grating calorimetry has been used to investigate the photochemical decomposition of diazomethane in benzene, and it appears that a transient is formed that is consistent with a weak complex between singlet methylene and benzene.²³²⁴ Chlorocarbene, $:CHCl$, is active enough to add to benzene, but dihalocarbenes do not add to benzene or toluene, only to rings with greater electron density. Pyrroles and indoles can be expanded, respectively, to pyridines and quinolines by treatment with halocarbenes²³²⁵ via the initially formed adduct **217** in the case of the indole.

In such cases, a side reaction that sometimes occurs is expansion of the six-membered ring. Ring expansion can occur even with non-aromatic compounds, when the driving force is supplied by relief of strain (see **218**).²³²⁶

As previously mentioned, free carbene is not very useful for additions to double bonds since it gives too many side products. The *Simmons–Smith procedure* accomplishes the same result without a free carbene intermediate and without insertion side products.²³²⁷ This procedure involves treatment of the double-bond compound with CH_2I_2 and a Zn–Cu couple and leads to cyclopropane derivatives in good yields.²³²⁸ The Zn–Cu couple can be prepared in several ways,²³²⁹ of which heating Zn dust with CuCl in ether under nitrogen²³³⁰ is particularly convenient. The reaction has also been done with unactivated zinc and ultrasound.²³³¹ When TiCl_4 is used along with Zn and CuCl, CH_2I_2 can be replaced by the cheaper CH_2Br_2 .²³³² The actual attacking species is an organozinc intermediate, probably $(\text{ICH}_2)_2\text{Zn}\cdot\text{ZnI}_2$, which is stable enough for isolable solutions.²³³³ An X-ray crystallographic investigation of the intermediate, complexed with a diether, has been reported.²³³⁴ The addition is stereospecifically syn, and a concerted mechanism²³³⁵ is likely, perhaps²³³⁶

Asymmetric induction is possible when chiral additives are used.²³³⁷ With the Simmons–Smith procedure, as with free carbenes, conjugated dienes give 1,2-addition,²³³⁸ and allenes give methylenecyclopropanes or spiropentanes.²³³⁹

An alternative way of carrying out the Simmons–Smith reaction is by treatment of the substrate with CH_2I_2 or another dihalomethane and Et_2Zn in ether.²³⁴⁰ This method can be adapted to the introduction of RCH and ArCH by the use of RCHI_2

or ArCHI_2 instead of the dihalomethane.²³⁴¹ The reaction is compatible with other functionality in the carbenoid complex. The reaction of $\text{RCO}_2\text{CH}_2\text{I}$ with diethyl zinc and an alkene under photolysis conditions give a cyclopropane.²³⁴² Chiral additives lead to enantioselectivity in the cyclopropanation reaction.²³⁴³ In another method, CH_2I_2 or MeCHI_2 is used along with an alane R_3Al to transfer CH_2 or CHMe .²³⁴⁴ Titanium complexes have been used similarly.²³⁴⁵ Samarium and CH_2I_2 has been used for the cyclopropanation of conjugated amides.²³⁴⁶ For the conversion of enolates to cyclopropanols, CH_2I_2 has been used along with SmI_2 .²³⁴⁷

Other cyclopropanation techniques have been developed. Treatment of an alkene with $\text{ArCH}(\text{SnBu}_3)\text{OCO}_2\text{Me}$ and $\text{BF}_3\cdot\text{OEt}_2$ leads to the cyclopropane with high cis-selectivity.²³⁴⁸ Diodomethane in the presence of isopropylmagnesium chloride has been used to cyclopropanate allyl alcohols.²³⁴⁹

The Simmons–Smith reaction is the basis of a method for the indirect α methylation of a ketone.²³⁵⁰ The ketone (illustrated for cyclohexanone) is first converted to an enol ether, an enamine (**16-13**) or silyl enol ether²³⁵¹ (**12-17**) and cyclopropanation via the Simmons–Smith reaction is followed by hydrolysis to give the α methylated ketone. A related procedure using diethylzinc and diiodomethane allows ketones to be chain-extended by one carbon.²³⁵² In another variation, phenols can be ortho-methylated in one laboratory step, by treatment with Et_2Zn and CH_2I_2 .²³⁵³

Diazoesters react with amines with a rhodium catalyst to give α -amino esters.²³⁵⁴ Diazoesters also react with aldehydes and a rhodium catalyst, and the product is an α,β -epoxy ester.²³⁵⁵ Diazoalkanes react similarly with aldehydes to give an alkene ($\text{Me}_3\text{SiCH}=\text{N}_2 + \text{ArCHO} \rightarrow \text{ArCH}=\text{CHOSiMe}_3$).²³⁵⁶

15-65 Trimerization and Tetramerization of Alkynes

Aromatic compounds can be prepared by cyclotrimerization of alkynes²³⁵⁷ or triynes. Cyclotrimerization is possible by heating to 450–600°C with no catalyst.²³⁵⁸ The *spontaneous* (no catalyst) trimerization of *t*-BuC≡CF gave 1,2,3-*tert*-butyl-4,5,6-trifluorobenzene (**220**), the first time three adjacent *tert*-butyl groups had been put onto a benzene ring.²³⁵⁹ The fact that this is a head-to-head joining allows formation of **220** from two alkynes. The fact that **219** (a Dewar benzene) was also isolated lends support to this scheme.²³⁶⁰ Three equivalents of 3-hexyne trimerized to hexaethylbenzene at 200°C in the presence of Si₂Cl₆.²³⁶¹

When acetylene is heated with nickel cyanide, other Ni(II) or Ni(0) compounds, or similar catalysts, it gives benzene and cyclooctatetraene.²³⁶² It is possible to get more of either product by a proper choice of catalyst. Substituted acetylenes give substituted benzenes.²³⁶³ This reaction has been used to prepare very crowded

molecules. Diisopropylacetylene was trimerized over $\text{CO}_2(\text{CO})_8$ ²³⁶⁴ and over $\text{Hg}[\text{Co}(\text{CO})_4]_2$ to hexaisopropylbenzene.²³⁶⁵ The six isopropyl groups are not free to rotate but are lined up perpendicular to the plane of the benzene ring. Highly substituted benzene derivatives have also been prepared using a rhodium,²³⁶⁶ nickel,²³⁶⁷ titanium,²³⁶⁸ molybdenum,²³⁶⁹ ruthenium,²³⁷⁰ cobalt,²³⁷¹ or a palladium²³⁷² catalyst. Alkynes react with allenes and a nickel catalyst go give highly substituted benzene derivatives.²³⁷³ Conjugated ketones react with internal alkynes with Me_3Al and a nickel catalyst²³⁷⁴ leads to an aromatic ring fused to a cyclic ketone after reaction with DBU and air.²³⁷⁵ *N*-Aryl chloroimines react with alkynes and a rhodium catalyst to give quinolines,²³⁷⁶ as do *N*-aryl alkynyl imines with a tungsten complex.²³⁷⁷

An intramolecular cyclotrimerization has been reported by condensation of a diyne²³⁷⁸ with an alkyne in the presence of a palladium,²³⁷⁹ molybdenum,²³⁸⁰ nickel,²³⁸¹ rhodium,²³⁸² iridium,²³⁸³ or ruthenium catalyst.²³⁸⁴ Triynes have been

similarly condensed with a rhodium catalyst.²³⁸⁵ The internal cyclotrimerization of a triyne, utilizing a siloxy tether and a cobalt catalyst has been reported.²³⁸⁶ Fused ring aromatic compounds are prepared by this method. Similar results were obtained from diynes and allenes with a nickel catalyst.²³⁸⁷ bis(Enynes) are cyclized to bicyclic arenes using a palladium catalyst.²³⁸⁸ Diynes with nitriles and a ruthenium catalyst lead to isoquinolines.²³⁸⁹ Pyridines fused to carboxylic rings can be prepared by similar methodology using a cyanoamine and a cobalt catalyst.²³⁹⁰ In the presence of PhMe_2SiH , CO and a rhodium catalyst, a nonconjugated triyne leads to a tricyclic compound in which a benzene ring is fused to two carbocyclic rings.²³⁹¹ Internal cyclotrimerization of an aryl alkynyl ketone where the aryl group has an *ortho* trimethylsilylalkyne substituent gives a tetracyclic naphthalene derivative with a fused cyclopentanone unit.²³⁹² An isocyanate (Ar-N=C=O) reacts with a diyne and a ruthenium catalyst to give a bicyclic pyridone.²³⁹³ Benzene derivatives with *ortho* alkyne units can be converted to naphthalene derivatives in aqueous NaOH with hydrazine, Te, NaBH_4 and sonication.²³⁹⁴ Benzene derivatives having *ortho* imine and alkyne substituents give an isoquinoline when treated with iodine²³⁹⁵ or with a palladium catalyst.²³⁹⁶ Imino and iodo substituents with a silyl alkyne and a palladium catalyst leads to an isoquinoline.²³⁹⁷ Vinyl and alkyne substituents with a ruthenium catalyst lead to naphthalene derivatives.²³⁹⁸ *Ortho* alkynyl and epoxy substituents leads to β -naphthols using a ruthenium catalyst.²³⁹⁹ Cyclotrimerization occurs with alkynyl boronic esters.²⁴⁰⁰

In contrast to the spontaneous reaction, the catalyzed process seldom gives the 1,2,3-trisubstituted benzene isomer from an acetylene $\text{RC}\equiv\text{CH}$. The chief product is usually the 1,2,4-isomer,²⁴⁰¹ with lesser amounts of the 1,3,15-isomer also generally obtained, but little if any of the 1,2,3-isomer. The mechanism of

the catalyzed

reaction to form benzenes²⁴⁰² is believed to go through a species **221** in which two molecules of alkyne coordinate with the metal, and another species **222**, a five-membered heterocyclic intermediate.²⁴⁰³ Such intermediates (where M = Rh, Ir, Zr,²⁴⁰⁴ or Ni) have been isolated and shown to give benzenes (**223**) when treated with alkynes.²⁴⁰⁵ Note that this pathway accounts for the predominant formation of the 1,2,4-isomer. Two possibilities for the last step are a Diels–Alder reaction, and a ring expansion, each followed by extrusion of the metal:²⁴⁰⁶

²⁴⁰²For studies of the mechanism of the reaction that produces cyclooctatetraenes, see Diercks, R.; Stamp, L.; Kopf, J.; Tom Dieck, H. *Angew. Chem. Int. Ed.* **1984**, *23*, 893; Colborn, R.E.; Vollhardt, K.P.C. *J. Am. Chem. Soc.* **1986**, *108*, 5470; Lawrie, C.J.; Gable, K.P.; Carpenter, B.K. *Organometallics* **1989**, *8*, 2274.

²⁴⁰³See, for example, Colborn, R.E.; Vollhardt, K.P.C. *J. Am. Chem. Soc.* **1981**, *103*, 6259; Kochi, J.K. *Organometallic Mechanisms and Catalysis*, Academic Press, NY, **1978**, pp. 428–432; Collman, J.P., Hegedus, L.S.; Norton, J.R.; Finke, R.G. *Principles and Applications of Organotransition Metal Chemistry*, University Science Books, Mill Valley, CA **1987**, pp. 870–877; Eisch, J.J.; Sexsmith, S.R. *Res. Chem. Intermed.* **1990**, *13*, 149–192.

²⁴⁰⁴Takahashi, T.; Ishikawa, M.; Huo, S. *J. Am. Chem. Soc.* **2002**, *124*, 388.

²⁴⁰⁵See, for example, Collman, J.P. *Acc. Chem. Res.* **1968**, *1*, 136; Yamazaki, H.; Hagihara, N. *J. Organomet. Chem.* **1967**, *7*, P22; Wakatsuki, Y.; Kuramitsu, T.; Yamazaki, H. *Tetrahedron Lett.* **1974**, 4549; Moseley, K.; Maitlis, P.M. *J. Chem. Soc. Dalton Trans.* **1974**, 169; Müller, E. *Synthesis* **1974**, 761; Eisch, J.J.; Galle, J.E. *J. Organomet. Chem.* **1975**, *96*, C23; McAlister, D.R.; Bercaw, J.E.; Bergman, R.G. *J. Am. Chem. Soc.* **1977**, *99*, 1666.

²⁴⁰⁶There is evidence that the mechanism of the last step more likely resembles the Diels–Alder pathway than the ring expansion pathway: Bianchini, C.; Caulton, K.G.; Chardon, C.; Eisenstein, O.; Foltling, K.; Johnson, T.J.; Meli, A.; Peruzzini, M.; Raucher, D.J.; Streib, W.E.; Vizza, F. *J. Am. Chem. Soc.* **1991**, *113*, 5127.

In at least one case the mechanism is different, going through a cyclobutadiene–nickel complex (see p. 76), which has been isolated.²⁴⁰⁷ Similar results were obtained with a titanium complex.²⁴⁰⁸ Using a mixture of PdCl₂ and CuCl₂, however, aliphatic alkynes are converted to the 1,3,5-trialkyl benzene derivative.²⁴⁰⁹

Alkoxy chromium carbenes (Fischer carbene complexes) react with phenylalkynes to give naphthalene derivatives.²⁴¹⁰ These chromium carbenes react with alkylnyl boronates, cerium(IV) compounds, and then PhBr and a palladium catalyst to give a naphthoquinone.²⁴¹¹ Diynes react to give cyclotrimerization.²⁴¹² It is noted that vinyl chromium carbenes react directly with alkynes to give spirocyclic compounds (spiro[4.4]nona-1,3,6-trienes).²⁴¹³ Benzofurans can be prepared using methoxy carbenes.²⁴¹⁴ Amino-substituted chromium carbenes react with alkynes and then silica to give substituted benzene derivatives that have an aminoalkyl (–NR₂) substituent.²⁴¹⁵ Imino-substituted chromium carbenes react with alkynes to give pyrrole derivatives.²⁴¹⁶ Fischer carbene complexes react with alkynes to give the *Dötz benzannulation*,²⁴¹⁷ giving *p*-alkoxyphenol derivatives. Modification of this basic technique can lead to eight-membered ring carbocycles (see 15-66).²⁴¹⁸

When benzene, in the gas phase, was adsorbed onto a surface of 10% rhodium-on-alumina, the reverse reaction took place, and acetylene was formed.²⁴¹⁹

In a related reaction, heating ketones in the presence of TiCl₃OTf leads to 1,3,5-trisubstituted arenes.²⁴²⁰ Heating acetophenone with TiCl₄ gives 1,3,5-triphenylbenzene.²⁴²¹ Nitriles react with 2 mol of acetylene, in the presence of a cobalt catalyst, to give 2-substituted pyridines.²⁴²² Propargyl amines react with cyclohexanone derivatives and a gold complex give tetrahydroquinolines.²⁴²³ Treatment of alkynes with Cp₂ZrEt₂ followed by reaction with acetonitrile and then a second alkyne with a nickel catalyst gives a highly substituted pyridine.²⁴²⁴ This reaction can be done intramolecularly using a photochemically induced reaction with a

15-66 Other Cycloaddition Reactions

cyclo-[But-2-en-1,4-diyl]-1/4/addition, and so on

Cycloaddition reactions other than [4 + 2], [3 + 2], or [2 + 2] are possible, often providing synthetically useful routes to cyclic compounds. Conjugated dienes can be dimerized or trimerized at their 1,4 positions (formally, [4 + 4] and [4 + 4 + 4]-cycloadditions) by treatment with certain complexes or other transition-metal compounds.²⁴²⁹ Thus butadiene gives 1,5-cyclooctadiene and 1,5,9-cyclododecatriene.²⁴³⁰ The relative amount of each product can be controlled by use of the proper catalyst. For example, Ni:P(OC₆H₄-*o*-Ph)₃ gives predominant dimerization, while Ni(cyclooctadiene)₂ gives mostly trimerization. The products arise, not by direct 1,4 to 1,4 attack, but by stepwise mechanisms involving metal-alkene complexes.²⁴³¹ The rhodium catalyzed intramolecular cycloaddition of a furan with a conjugated diazoester gives a [3 + 4]-cycloadduct.²⁴³² The suprafacial thermal addition of an allylic cation to a diene (a [4 + 3]-cycloaddition) is allowed by the Woodward-Hoffmann rules (this reaction would

be expected to follow the same rules as the Diels–Alder reaction²⁴³³). Chiral cations have been used in [4 + 3]-cycloadditions.²⁴³⁴

As we saw in **15-60**, the Woodward–Hoffmann rules allow suprafacial concerted cycloadditions to take place thermally if the total number of electrons is $4n+2$ and photochemically if the number is $4n$. Furthermore, forbidden reactions become allowed if one molecule reacts antarafacially. It would thus seem that syntheses of many large rings could easily be achieved. However, when the newly formed ring is eight-membered or greater, concerted mechanisms, although allowed by orbital symmetry for the cases stated, become difficult to achieve because of the entropy factor (the two ends of one system must simultaneously encounter the two ends of the other), unless one or both components are cyclic, in which case the molecule has many fewer possible conformations. There have been a number of reports of cycloaddition reactions leading to eight-membered and larger rings, some thermally and some photochemically induced, but (apart from the dimerization and trimerization of butadienes mentioned above, which are known not to involve direct [4 + 4]- or [4 + 4 + 4]-cycloaddition) in most cases evidence is lacking to indicate whether they are concerted or stepwise processes. Some examples are

Addition to Carbon–Hetero Multiple Bonds

MECHANISM AND REACTIVITY

The reactions considered in this chapter involve addition to the carbon–oxygen, carbon–nitrogen, and carbon–sulfur double bonds, and the carbon–nitrogen triple bond. The mechanistic study of these reactions is much simpler than that of the additions to carbon–carbon multiple bonds considered in Chapter 15.¹ Most of the questions that concerned us there either do not arise here or can be answered very simply. Since C=O, C=N, and C≡N bonds are strongly polar, with the carbon always the positive end (except for isocyanides, see p. 1466), there is never any doubt about the *orientation* of unsymmetrical addition to these bonds. Nucleophilic attacking species always go to the carbon and electrophilic species to the oxygen or nitrogen. Additions to C=S bonds are much less common,² but in these cases the addition can be in the other direction.³ For example, thiobenzophenone (Ph₂C=S), when treated with phenyllithium gives, after hydrolysis, benzhydryl phenyl sulfide (Ph₂CHSPh).⁴

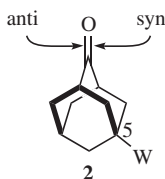

¹For a discussion, see Jencks, W.P. *Prog. Phys. Org. Chem.* **1964**, *2*, 63.

²For reviews of thioketones and other compounds with C=S bonds, see Schaumann, E., in Patai, S. *Supplement A: The Chemistry of Double-Bonded Functional Groups*, Vol. 2, pt. 2, Wiley, NY, **1989**, pp. 1269–1367; Ohno, A. in Oae, S. *Organic Chemistry of Sulfur*, Plenum, NY, **1977**, pp. 189–229; Mayer, R., in Janssen, M.J. *Organosulfur Chemistry*, Wiley, NY, **1967**, pp. 219–240; Campaigne, E., in Patai, S. *The Chemistry of the Carbonyl Group*, pt. 1, Wiley, NY, **1966**, pp. 917–959.

³For a review of additions of organometallic compounds to C=S bonds, both to the sulfur (*thiophilic addition*) and to the carbon (*carbophilic addition*), see Wardell, J.L.; Paterson, E.S., in Hartley, F.P.; Patai, S. *The Chemistry of the Metal-Carbon Bond*, Vol. 2, Wiley, NY, **1985**, pp. 219–338, 261–267.

⁴Beak, P.; Worley, J.W. *J. Am. Chem. Soc.* **1972**, *94*, 597. For some other examples, see Schaumann, E.; Walter, W. *Chem. Ber.* **1974**, *107*, 3562; Metzner, P.; Vialle, J.; Vibet, A. *Tetrahedron* **1978**, *34*, 2289.

In addition of YH to a ketone to give **1** the product has a stereogenic carbon, but unless there is chirality in R or R' or YH is optically active, the product must be a racemic mixture because there is no facial bias about the carbonyl. The same holds true for C=N and C=S bonds, since in none of these cases can chirality be present at the heteroatom. The stereochemistry of addition of a single YH to the carbon–nitrogen triple bond could be investigated, since the product can exist in (*E*) and (*Z*) forms (p. 183), but these reactions generally give imine products that undergo further reaction. Of course, if R or R' is chiral, a racemic mixture will not always arise and the stereochemistry of addition can be studied in such cases. Cram's rule (p. 168) allows us to predict the direction of attack of Y in many cases.⁵ However, even in this type of study, the relative directions of attack of Y and H are not determined, but only the direction of attack of Y with respect to the rest of the substrate molecule.

On p. 1023, it was mentioned that electronic effects can play a part in determining which face of a carbon–carbon double bond is attacked. The same applies to additions to carbonyl groups. For example, in 5-substituted adamantanones (**2**) electron-withdrawing (*-I*) groups W cause the attack to come from the syn face, while electron-donating groups cause it to come from the anti face.⁶ In 5,6-disubstituted norborn-2-en-7-one systems, the carbonyl appears to tilt away from the π -bond, with reduction occurring from the more hindered face.⁷ An *ab initio* study of nucleophilic addition to 4-*tert*-butylcyclohexanones attempted to predict π -facial selectivity in that system.⁸

The mechanistic picture is further simplified by the fact that free-radical additions to carbon–heteroatom double bonds are not as prevalent.⁹ In most cases, it

is the nucleophile that forms the first new bond to carbon, and these reactions are regarded as *nucleophilic additions*, which can be represented thus (for the C=O bond, analogously for the others):

The electrophile shown in step 2 is the proton. In almost all the reactions considered in this chapter, the electrophilic atom is either hydrogen or carbon. Note that step 1 is exactly the same as step 1 of the tetrahedral mechanism of nucleophilic substitution at a carbonyl carbon (p. 1255), but carbon groups (A, B = H, alkyl aryl, etc.) are poor leaving groups so that substitution does not compete with addition. For carboxylic acids and their derivatives (B = OH, OR, NH₂, etc.) much better leaving groups are available and acyl substitution predominates (p. 1254). It is thus the nature of A and B that determines whether a nucleophilic attack at a carbon–heteroatom multiple bond will lead to substitution or addition.

It is also possible for the heteroatom (oxygen in a carbonyl) to react as a base, attacking the electrophilic species. This species is most often a proton and the mechanism is

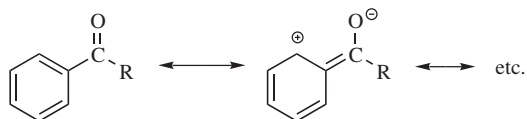

Whether the nucleophile attacks the carbon or the heteroatom attacks the electrophilic species, the rate-determining step is usually the one involving nucleophilic attack. It may be observed that many of these reactions can be catalyzed by both acids and bases.¹⁰ Bases catalyze the reaction by converting a reagent of the form YH to the more powerful nucleophile Y[−] (see p. 490). Acids catalyze it by converting the substrate to an heteroatom-stabilized cation (formation of **3**), thus making it more attractive to nucleophilic attack. Similar catalysis can also be found with metallic ions (e.g., Ag⁺) which act here as Lewis acids.¹¹ We have mentioned before (p. 242) that ions of type **3** are comparatively stable carbocations because the positive charge is spread by resonance.

¹⁰For a discussion of acid and base catalysis in these reactions, see Jencks, W.P.; Gilbert, H.F. *Pure Appl. Chem.* **1977**, *49*, 1021.

¹¹Toromanoff, E. *Bull. Soc. Chim. Fr.* **1962**, 1190.

Reactivity factors in additions to carbon–heteroatom multiple bonds are similar to those for the tetrahedral mechanism of nucleophilic substitution.¹² If A and/or B are electron-donating groups, rates are decreased. Electron-attracting substituents increase rates. This means that aldehydes are more reactive than ketones. Aryl groups are somewhat deactivating compared to alkyl, because of resonance that stabilizes the substrate molecule, but is lost on going to the intermediate:

Double bonds in conjugation with the carbon–heteroatom multiple bond also lower addition rates, for similar reasons but, more important, may provide competition from 1,4-addition (p. 1008). Steric factors are also quite important and contribute to the decreased reactivity of ketones compared with aldehydes. Highly hindered ketones like hexamethylacetone and dioneopentyl ketone either do not undergo many of these reactions or require extreme conditions.

Nucleophilic Substitution at an Aliphatic Trigonal Carbon: The Tetrahedral Mechanism

All the mechanisms so far discussed take place at a saturated carbon atom. Nucleophilic substitution is also important at trigonal carbons, especially when the carbon is double bonded to an oxygen, a sulfur, or a nitrogen. Substitution at a carbonyl group (or the corresponding nitrogen and sulfur analogs) most often proceeds by a second-order mechanism, which in this book is called the *tetrahedral*¹³ *mechanism*.¹⁴ The IUPAC designation is $A_N + D_N$. The S_N1 mechanisms, involving carbocations, are sometimes found with these substrates, especially with essentially ionic substrates such as $RCO^+ BF_4^-$; there is evidence that in certain cases simple S_N2 mechanisms can take place, especially with a very good leaving group such as Cl^- .¹⁵

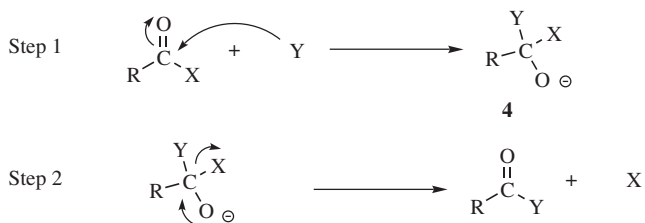

¹²For a review of the reactivity of nitriles, see Schaefer, F.C., in Rappoport, Z. *The Chemistry of the Cyano Group*, Wiley, NY, **1970**, pp. 239–305.

¹³This mechanism has also been called the “addition-elimination mechanism,” but in this book we limit this term to the type of mechanism shown on p. \$\$\$.

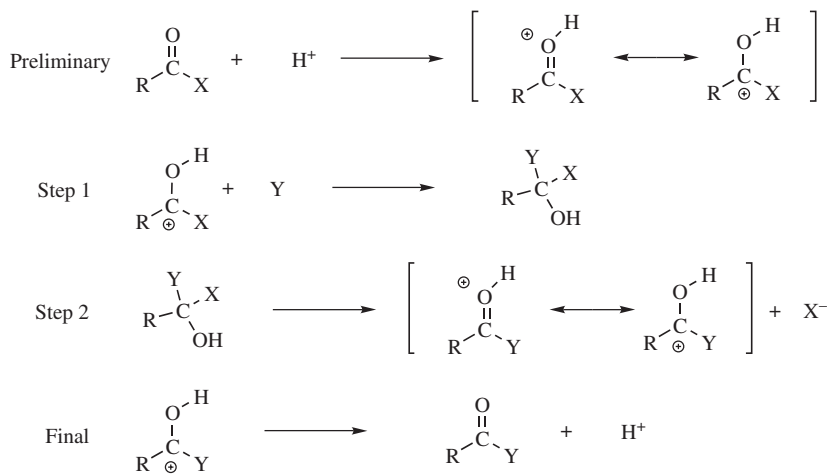

¹⁴For reviews of this mechanism, see Talbot, R.J.E., in Bamford, C.H.; Tipper, C.F.H. *Comprehensive Chemical Kinetics*, Vol. 10, Elsevier, NY, **1972**, pp. 209–223; Jencks, W.P. *Catalysis in Chemistry and Enzymology*, McGraw-Hill, NY, **1969**, pp. 463–554; Satchell, D.P.N.; Satchell, R.S., in Patai, S. *The Chemistry of Carboxylic Acids and Esters*, Wiley, NY, **1969**, pp. 375–452; Johnson, S.L. *Adv. Phys. Org. Chem.* **1967**, *5*, 237.

¹⁵For a review, see Williams, A. *Acc. Chem. Res.* **1989**, *22*, 387. For examples, see Kevill, D.N.; Foss, F.D. *J. Am. Chem. Soc.* **1969**, *91*, 5054; Haberfield, P.; Trattner, R.B. *Chem. Commun.* **1971**, 1481; De Tar, D.F. *J. Am. Chem. Soc.* **1982**, *104*, 7205; Shpan’ko, I.V.; Goncharov, A.N. *J. Org. Chem. USSR* **1987**, *23*, 2287; Guthrie, J.P.; Pike, D.C. *Can. J. Chem.* **1987**, *65*, 1951; Kevill, D.N.; Kim, C. *Bull. Soc. Chim. Fr.* **1988**, 383; *J. Chem. Soc. Perkin Trans. 2* **1988**, 1353; Bentley, T.W.; Koo, I.S. *J. Chem. Soc. Perkin Trans. 2* **1989**, 1385. See, however, Buncel, E.; Um, I.H.; Hoz, S. *J. Am. Chem. Soc.* **1989**, *111*, 971.

and an SET mechanism has also been reported.¹⁶ However, the tetrahedral mechanism is by far the most prevalent. Although this mechanism displays second-order kinetics, it is not the same as the S_N2 mechanism previously discussed. In the tetrahedral mechanism, first Y attacks to give an intermediate containing both X and Y (**4**), and then X leaves. This sequence, impossible at a saturated carbon, is possible at an unsaturated one because the central carbon can release a pair of electrons to the oxygen and so preserve its octet:

When reactions are carried out in acid solution, there may also be a preliminary and a final step:

The hydrogen ion is a catalyst. The reaction rate is increased because it is easier for the nucleophile to attack the carbon when the electron density of the latter has been decreased.¹⁷

Evidence for the existence of the tetrahedral mechanism is as follows:¹⁸

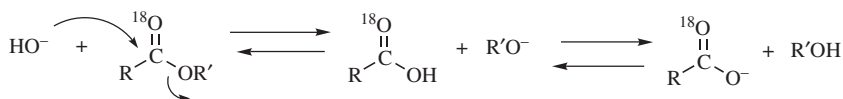

1. The kinetics are first order each in the substrate and in the nucleophile, as predicted by the mechanism.

¹⁶Bacaloglu, R.; Blaskó, A.; Bunton, C.A.; Ortega, F. *J. Am. Chem. Soc.* **1990**, *112*, 9336.

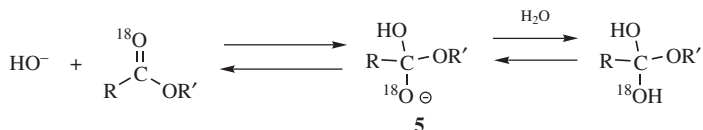

¹⁷For discussions of general acid and base catalysis of reactions at a carbonyl group, see Jencks, W.P. *Acc. Chem. Res.* **1976**, *9*, 425; *Chem. Rev.* **1972**, *72*, 705.

¹⁸For additional evidence, see Guthrie, J.P. *J. Am. Chem. Soc.* **1978**, *100*, 5892; Kluger, R.; Chin, J. *J. Am. Chem. Soc.* **1978**, *100*, 7382; O'Leary, M.H.; Marlier, J.F. *J. Am. Chem. Soc.* **1979**, *101*, 3300.

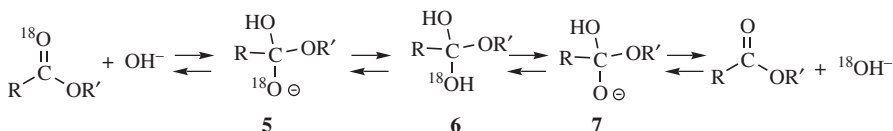

2. There is other kinetic evidence in accord with a tetrahedral intermediate. For example, the rate "constant" for the reaction between acetamide and hydroxylamine is not constant, but decreases with increasing hydroxylamine concentration.¹⁹ This is not a smooth decrease; there is a break in the curve. A straight line is followed at low hydroxylamine concentration and another straight line at high concentration. This means that the identity of the rate-determining step is changing. Obviously, this cannot happen if there is only one step: there must be two steps, and hence an intermediate. Similar kinetic behavior has been found in other cases as well,²⁰ in particular, plots of rate against pH are often bell shaped.
3. Basic hydrolysis has been carried out on carboxylic esters labeled with ¹⁸O in the carbonyl group.²¹ If this reaction proceeded by the normal S_N2 mechanism, all the ¹⁸O would remain in the carbonyl group, even if, in an equilibrium process, some of the carboxylic acid formed went back to the starting material:

On the other hand, if the tetrahedral mechanism operates

then the intermediate **5**, by gaining a proton, becomes converted to the symmetrical intermediate **6**. In this intermediate the OH groups are equivalent, and (except for the small ¹⁸O/¹⁶O isotope effect) either one can lose a proton with equal facility:

The intermediates **5** and **7** can now lose OR' to give the acid (not shown in the equations given), or they can lose OH to regenerate the carboxylic ester. If **5** goes back to ester, the ester will still be labeled, but if **7** reverts to ester, the

^{18}O will be lost. A test of the two possible mechanisms is to stop the reaction before completion and to analyze the recovered ester for ^{18}O . This is just what was done by Bender, who found that in alkaline hydrolysis of methyl, ethyl, and isopropyl benzoates, the esters had lost ^{18}O . A similar experiment carried out for acid-catalyzed hydrolysis of ethyl benzoate showed that here too the ester lost ^{18}O . However, alkaline hydrolysis of substituted benzyl benzoates showed *no* ^{18}O loss.²² This result does not necessarily mean that no tetrahedral intermediate is involved in this case. If **5** and **7** do not revert to ester, but go entirely to acid, no ^{18}O loss will be found even with a tetrahedral intermediate. In the case of benzyl benzoates, this may very well be happening, because formation of the acid relieves steric strain. Another possibility is that **5** loses OR' before it can become protonated to **6**.²³ Even the experiments that *do* show ^{18}O loss do not *prove* the existence of the tetrahedral intermediate, since it is possible that ^{18}O is lost by some independent process not leading to ester hydrolysis. To deal with this possibility, Bender and Heck²⁴ measured the rate of ^{18}O loss in the hydrolysis of ethyl trifluoroacetate- ^{18}O :

This reaction had previously been shown²⁵ to involve an intermediate by the kinetic methods mentioned on p. 1256. Bender and Heck showed that the rate of ^{18}O loss and the value of the partitioning ratio k_2/k_3 as determined by the oxygen exchange technique were exactly in accord with these values as previously determined by kinetic methods. Thus the original ^{18}O -exchange measurements showed that there is a tetrahedral species present, though not necessarily on the reaction path, while the kinetic experiments showed that there is some intermediate present, though not necessarily tetrahedral. Bender and Heck's results demonstrate that there is a tetrahedral intermediate and that it lies on the reaction pathway.

4. In some cases, tetrahedral intermediates have been isolated²⁶ or detected spectrally.²⁷

Several studies have been made of the directionality of approach by the nucleophile.²⁸ Menger has proposed for reactions in general, and specifically for those that proceed by the tetrahedral mechanism, that there is no single definable preferred transition state, but rather a "cone" of trajectories. All approaches within this cone lead to reaction at comparable rates; it is only when the approach comes outside of the cone that the rate falls.

Directionality has also been studied for the second step. Once the tetrahedral intermediate (**4**) is formed, it loses Y (giving the product) or X (reverting to the starting compound). Deslongchamps has proposed that one of the factors affecting this choice is the conformation of the intermediate; more specifically, the positions of the lone pairs. In this view, a leaving group X or Y can depart only if the other two atoms on the carbon both have an orbital antiperiplanar to the C-X or C-Y bond. For example, consider an intermediate **8** formed by attack of ⁻OR on a substrate R'COX. Cleavage of the C-X bond with loss of X can take place from conformation **A**, because the two lone-pair orbitals marked * are antiperiplanar to the C-X bond, but not from **B** because only the O⁻ has such an orbital. If the intermediate is in conformation **B**, the OR may leave (if X has a lone-pair orbital in the proper position) rather than X. This factor is called *stereoelectronic control*.²⁹ Of course, there is free rotation in acyclic intermediates, and many conformations are possible, but some are preferred, and cleavage reactions may take place faster than rotation, so stereoelectronic control can be a factor in some situations. Much evidence has been presented for this concept.³⁰ More generally, the term *stereoelectronic effects* refers to any case in which orbital

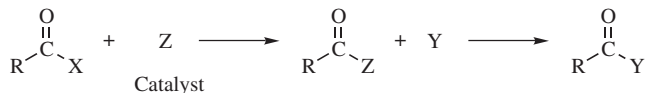

²⁸For discussions, see Menger, F.M. *Tetrahedron* **1983**, *39*, 1013; Liotta, C.L.; Burgess, E.M.; Eberhardt, W.H. *J. Am. Chem. Soc.* **1984**, *106*, 4849.

²⁹It has also been called the "antiperiplanar lone pair hypothesis (ALPH)." For a reinterpretation of this factor in terms of the principle of least nuclear motion (see **15-10**), see Hosie, L.; Marshall, P.J.; Sinnott, M.L. *J. Chem. Soc. position requirements affect the course of a reaction. The backside attack in the S_N2 mechanism is an example of a stereoelectronic effect.

Some nucleophilic substitutions at a carbonyl carbon are *catalyzed* by nucleophiles.³¹ There occur, in effect, two tetrahedral mechanisms:

(For an example, see 16-58). When this happens internally, we have an example of a neighboring-group mechanism at a carbonyl carbon.³² For example, the hydrolysis of phthalamic acid (**9**) takes place as follows:

Evidence comes from comparative rate studies.³³ Thus **9** was hydrolyzed $\sim 10^5$ times faster than benzamide (PhCONH_2) at about the same concentration of hydrogen ions. That this enhancement of rate was not caused by the resonance or field effects of COOH (an electron-withdrawing group) was shown by the fact both *o*-nitrobenzamide and terephthalamic acid (the para isomer of **9**) were hydrolyzed more slowly than benzamide. Many other examples of neighboring-group participation at a carbonyl carbon have been reported.³⁴ It is likely that nucleophilic catalysis is involved in enzyme catalysis of ester hydrolysis.

The attack of a nucleophile on a carbonyl group can result in substitution or addition, though the first step of each mechanism is the same. The main factor that determines the product is the identity of the group X in RCOX . When X is alkyl or hydrogen, addition usually takes place. When X is halogen, OH, OCOR, NH_2 , and so on, the usual reaction is substitution.

In both the S_N1 and S_N2 mechanisms, the leaving group departs during the rate-determining step and so directly affects the rate. In the tetrahedral mechanism at a carbonyl carbon, the bond between the substrate and leaving group is still intact during the slow step. Nevertheless, the nature of the leaving group still affects the reactivity in two ways: (1) By altering the

^aCatalysts are not shown.

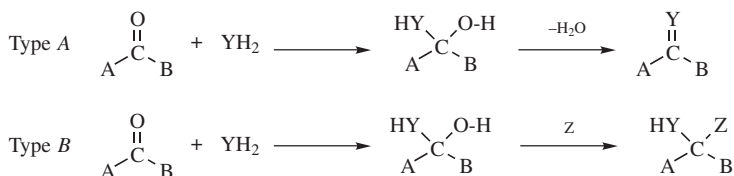

electron density at the carbonyl carbon, the rate of the reaction is affected. The greater the electron-withdrawing character of X, the greater the partial positive charge on C and the more rapid the attack by a nucleophile. (2) The nature of the leaving group affects the *position of equilibrium*. In the intermediate **4** (p. 1255), there is competition between X and Y as to which group leaves. If X is a poorer leaving group than Y, then Y will preferentially leave and **4** will revert to the starting compounds. Thus there is a partitioning factor between **4** going on to product (loss of X) or back to starting compound (loss of Y). The sum of these two factors causes the sequence of reactivity to be $\text{RCOCl} > \text{RCOOCOR}' > \text{RCOOAr} > \text{RCOOR}' > \text{RCONH}_2 > \text{RCONR}'_2 > \text{RCOO}^-$.³⁵ Note that this order is approximately the order of decreasing stability of the leaving-group anion. If the leaving group is bulky, it may exert a steric effect and retard the rate for this reason.

For a list of some of the more important reactions that operate by the tetrahedral mechanism, see Table 16.1, which shows the main reactions that proceed by the tetrahedral mechanism.

³⁵RCOOH would belong in this sequence just after RCOOAr, but it fails to undergo many reactions for a special reason. Many nucleophiles, instead of attacking the C=O group, are basic enough to take a proton from the acid, converting it to the unreactive RCOO⁻.

REACTIONS

Many of the reactions in this chapter are simple additions to carbon–hetero multiple bonds, with the reaction ending when the two groups have been added. But in many other cases subsequent reactions take place. We will meet a number of such reactions, but most are of two types:

In type A, the initially formed adduct loses water (or, in the case of addition to C=NH, ammonia, etc.), and the net result of the reaction is the substitution of C=Y for C=O (or C=NH, etc.). In type B, there is a rapid substitution, and the OH (or NH₂, etc.) is replaced by another group Z, which is often another YH moiety. This substitution is in most cases nucleophilic, since Y usually has an unshared pair and S_N1 reactions occur very well on this type of compound (see p. 482), even when the leaving group is as poor as OH or NH₂. In this chapter, we will classify reactions according to what is initially adding to the carbon–hetero multiple bond, even if subsequent reactions take place so rapidly that it is not possible to isolate the initial adduct.

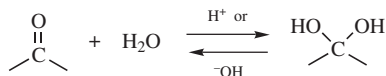

Most of the reactions considered in this chapter can be reversed. In many cases, we will consider the reverse reactions with the forward ones, in the same section. The reverse of some of the other reactions are considered in other chapters. In still other cases, one of the reactions in this chapter is the reverse of another (e.g., **16-2** and **16-13**). For reactions that are reversible, the principle of microscopic reversibility (p. 309) applies.

First, we will discuss reactions in which hydrogen or a metallic ion (or in one case phosphorus or sulfur) adds to the heteroatom and second reactions in which carbon adds to the heteroatom. Within each group, the reactions are classified by the nature of the nucleophile. Additions to isocyanides, which are different in character, follow. Acyl substitution reactions that proceed by the tetrahedral mechanism, which mostly involve derivatives of carboxylic acids, are treated at the end.

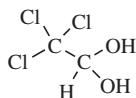

REACTIONS IN WHICH HYDROGEN OR A METALLIC ION ADDS TO THE HETEROATOM

A. Attack by OH (Addition of H₂O)

16-1 The Addition of Water to Aldehydes and Ketones: Formation of Hydrates

O-Hydro-C-hydroxy-addition

The adduct formed upon addition of water to an aldehyde or ketone is called a hydrate or *gem*-diol.³⁶ These compounds are usually stable only in water solution and decompose on distillation; that is, the equilibrium shifts back toward the carbonyl compound. The position of the equilibrium is greatly dependent on the structure of the hydrate. Thus, formaldehyde in water at 20°C exists 99.99% in the hydrated form, while for acetaldehyde this figure is 58%, and for acetone the hydrate concentration is negligible.³⁷ It has been found, by exchange with ¹⁸O, that the reaction with acetone is quite rapid when catalyzed by acid or base, but the equilibrium lies on the side of acetone and water.³⁸ Since methyl, a +I group, inhibits hydrate formation, it may be expected that electron-attracting groups would have the opposite effect, and this is indeed the case. The hydrate of chloral (trichloroacetaldehyde)³⁹ is a stable crystalline substance. In order for it to revert to chloral, ⁻OH or H₂O must leave; this is made difficult by the electron-withdrawing character of the Cl₃C group. Some other⁴⁰ polychlorinated and polyfluorinated

Chloral hydrate

Hydrate of cyclopropanone

aldehydes and ketones⁴¹ and α -keto aldehydes also form stable hydrates, as do cyclopropanones.⁴² In the last case,⁴³ formation of the hydrate relieves some of the *I* strain (p. 399) of the parent ketone.

The reaction is subject to both general-acid and general-base catalysis; the following mechanisms can be written for basic (B) and acidic (BH) catalysis, respectively:⁴⁴

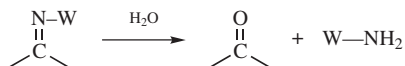

In mechanism *a*, as the H₂O attacks, the base pulls off a proton, and the net result is addition of ⁻OH. This can happen because the base is already hydrogen bonded to the H₂O molecule before the attack. In mechanism *b*, because HB is already hydrogen bonded to the oxygen of the carbonyl group, it gives up a proton to the oxygen as the water attacks. In this way, B and HB accelerate the reaction even beyond the extent that they form ⁻OH or H₃O⁺ by reaction with water. Reactions in which the catalyst donates a proton to the electrophilic reagent (in this case the aldehyde or ketone) in one direction and removes it in the other are called class e reactions. Reactions in which the catalyst does the same to the nucleophilic reagent are called class n reactions.⁴⁵ Thus the acid-catalyzed process here is a class e reaction, while the base catalyzed process is a class n reaction.

For the reaction between ketones and H₂O₂, see **17-37**.

There are no OS references, but see OS **VIII**, 597, for the reverse reaction.

16-2 Hydrolysis of the Carbon-Nitrogen Double Bond⁴⁶

Oxo-de-alkylimino-bisubstitution, and so on

Compounds containing carbon–nitrogen double bonds can be hydrolyzed to the corresponding aldehydes or ketones.⁴⁷ For imines (W = R or H) the hydrolysis is easy and can be carried out with water. When W = H, the imine is seldom stable enough for isolation, and in aqueous media hydrolysis usually occurs *in situ*, without isolation. The hydrolysis of Schiff bases (W = Ar) is more difficult and requires

acid or base catalysis. Oximes (W = OH), arylhydrazones (W = NHAr), and, most easily, semicarbazones (W = NHCONH₂) can also be hydrolyzed. Often a reactive aldehyde (e.g., formaldehyde) is added to combine with the liberated amine.

A number of other reagents⁴⁸ have been used to cleave C=N bonds, especially those not easily hydrolyzable with acidic or basic catalysts or that contain other functional groups that are attacked under these conditions. Oximes have been converted to the corresponding aldehyde or ketone⁴⁹ by treatment with, among other reagents, NBS in water,⁵⁰ glyoxylic acid (HCOCOOH),⁵¹ Chloramine-T⁵² Caro's acid on SiO₂,⁵³ HCOOH on SiO₂ with microwave irradiation,⁵⁴ bromosulfonamides,⁵⁵ SiBr₄ on wet silica,⁵⁶ and KMnO₄ on Al₂O₃⁵⁷ or on zeolite.⁵⁸ Chromate oxidizing agents can be quite effective, including tetraethylammonium permanganate,⁵⁹ tetraalkylammonium dichromate with microwave irradiation,⁶⁰ pyridinium fluorochromate,⁶¹ quinolinium fluorochromate⁶² or dichromate.⁶³ Alkaline H₂O₂,⁶⁴ iodine in acetonitrile,⁶⁵ singlet oxygen with NaOMe/MeOH⁶⁶ and with an ionic liquids on SiO₂⁶⁷ have also been used. Transition-metal compounds have been used, including SbCl₅,⁶⁸ Co₂(CO)₈,⁶⁹ Hg(NO₃)₂/SiO₂,⁷⁰ or BiBr₃–Bi(OTf)₃ in aqueous media,⁷¹ Bi(NO₃)₃/SiO₂,⁷² a nickel(II) complex

It is thus an example of reaction type A (p. 1261). The sequence shown is generalized.⁹⁸ In specific cases, there are variations in the sequence of the steps, depending on acid or basic catalysis or other conditions.⁹⁹ Which step is rate determining also depends on acidity and on the nature of W and of the groups connected to the carbonyl.¹⁰⁰

Iminium ions (**10**)¹⁰¹ would be expected to undergo hydrolysis quite readily, since there is a contributing form with a positive charge on the carbon. Indeed, they react with water at room temperature.¹⁰² Acid-catalyzed hydrolysis of enamines (the last step of the Stork reaction, **10-69** involves conversion to iminium ions:¹⁰³

The mechanism of enamine hydrolysis is thus similar to that of vinyl ether hydrolysis (**10-6**).

16-3 Hydrolysis of Aliphatic Nitro Compounds

Oxo-de-hydro,nitro-bisubstitution

Primary or secondary aliphatic nitro compounds can be hydrolyzed, respectively, to aldehydes or ketones, by treatment of their conjugate bases with sulfuric acid. This is called the *Nef reaction*.¹⁰⁵ Tertiary aliphatic nitro compounds do not give the reaction because they cannot be converted to their conjugate bases. Like **16-2**, this reaction involves hydrolysis of a C=N double bond. A possible mechanism is¹⁰⁶

Intermediates of type **12** have been isolated in some cases.¹⁰⁷

The conversion of nitro compounds to aldehydes or ketones has been carried out with better yields and fewer side reactions by several alternative methods.¹⁰⁸ Among these are treatment of the nitro compound with tin complexes and NaHSO₃,¹⁰⁹ activated dry silica gel,¹¹⁰ or 30% H₂O₂-K₂CO₃,¹¹¹ *t*-BuOOH and a catalyst,¹¹²

DBU in acetonitrile,¹¹³ NaH and Me₃SiOOSiMe₃,¹¹⁴ NaNO₂ in aq. DMSO,¹¹⁵ or ceric ammonium nitrate (CAN).¹¹⁶ The reaction of Al–NiCl₂·6 H₂O in THF converted α,β-unsaturated nitro compounds to the corresponding aldehyde, PhCH=CHNO₂ → PhCH₂CHO.¹¹⁷

When *primary* nitro compounds are treated with sulfuric acid without previous conversion to the conjugate bases, they give carboxylic acids. Hydroxamic acids are intermediates and can be isolated, so that this is also a method for preparing them.¹¹⁸ Both the Nef reaction and the hydroxamic acid process involve the aci form; the difference in products arises from higher acidity, for example, a difference in sulfuric acid concentration from 2 to 15.5 M changes the product from the aldehyde to the hydroxamic acid.¹¹⁹ The mechanism of the hydroxamic acid reaction is not known with certainty, but if higher acidity is required, it may be that the protonated aci form of the nitro compound is further protonated.

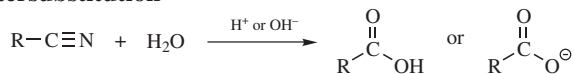

OS VI, 648; VII, 414. See also OS IV, 573.

16-4 Hydrolysis of Nitriles

NN-Dihydro-*C*-oxo-biaddition

Hydroxy,oxo-de-nitrilo-tersubstitution

Nitriles can be hydrolyzed to give either amides or carboxylic acids.¹²⁰ The amide is formed initially, but since amides are also hydrolyzed with acid or basic treatment, the carboxylic acid is readily formed. When the acid is desired,¹²¹ the reagent of choice is aq. NaOH containing ~6–12% H₂O₂, though acid-catalyzed hydrolysis is also frequently carried out. A “dry” hydrolysis of nitriles has been reported.¹²² The hydrolysis of nitriles to carboxylic acids is one of the best methods for the preparation of these compounds. Nearly all nitriles give the reaction, with either acidic or basic catalysts. Hydrolysis of cyanohydrins, RCH(OH)CN, is usually carried out under acidic conditions, because basic solutions cause competing

reversion of the cyanohydrin to the aldehyde and CN^- . However, cyanohydrins have been hydrolyzed under basic conditions with borax or alkaline borates.¹²³ Enzymatic hydrolysis with *Rhodococcus* sp AJ270 has also been reported.¹²⁴ In methanol with $\text{BF}_3 \cdot \text{OEt}_2$, benzonitrile is converted to methyl benzoate.¹²⁵

There are a number of procedures for stopping at the amide stage,¹²⁶ among them the use of concentrated H_2SO_4 ; 2 equivalents of chlorotrimethylsilane followed by H_2O ,¹²⁷ aq. NaOH with PEG-400 and microwave irradiation,¹²⁸ NaBO_3 with 4 equivalents of water and microwave irradiation,¹²⁹ heating on neutral alumina,¹³⁰ Oxone[®],¹³¹ and dry HCl followed by H_2O . The same result can also be obtained by use of water and certain metal ions or complexes;¹³² a ruthenium catalyst on alumina with water,¹³³ $\text{MnO}_2/\text{SiO}_2$ with microwave irradiation,¹³⁴ $\text{Hg}(\text{OAc})_2$ in HOAc,¹³⁵ or 2-mercaptoethanol in a phosphate buffer.¹³⁶ Nitriles can be hydrolyzed to the carboxylic acids without disturbing carboxylic ester functions also present, by the use of tetrachloro- or tetrafluorophthalic acid.¹³⁷ Nitriles are converted to thioamides $\text{ArC}(=\text{S})\text{NH}_2$ with ammonium sulfide $(\text{NH}_4)_2\text{S}$ in methanol, with microwave irradiation.¹³⁸

Thiocyanates are converted to thiocarbamates in a similar reaction:¹³⁹
 $\text{R}-\text{S}-\text{C}\equiv\text{N} + \text{H}_2\text{O} \rightarrow \text{R}-\text{S}-\text{C}-\text{O}-\text{NH}_2$. Hydrolysis of cyanamides gives amines, produced by the breakdown of the unstable carbamic acid intermediates: $\text{R}_2\text{NCN} \rightarrow [\text{R}_2\text{NCOOH}] \rightarrow \text{R}_2\text{NH}$.

B. Attack by OR or SR (Addition of ROH; RSH)**16-5 The Addition of Alcohols to Aldehydes and Ketones****Dialkoxy-de-oxo-bisubstitution****Dithioalkyl-de-oxo-bisubstitution**

Acetals and ketals are formed by treatment of aldehydes and ketones, respectively, with alcohols in the presence of acid catalysts.¹⁴⁰ Lewis acids such as TiCl_4 ¹⁴¹ RuCl_3 ,¹⁴² or CoCl_2 ¹⁴³ can be used in conjunction with alcohols. Dioxolanes have been prepared in ethylene glycol using microwave irradiation and *p*-toluenesulfonic acid as a catalyst.¹⁴⁴ This reaction is reversible, and acetals and ketals can be hydrolyzed by treatment with acid.¹⁴⁵ With small unbranched aldehydes the equilibrium lies to the right. If ketals or acetals of larger molecules must be prepared the equilibrium must be shifted, usually by removal of water. This can be done by azeotropic distillation, ordinary distillation, or the use of a drying agent such as Al_2O_3 or a molecular sieve.¹⁴⁶ The reaction is not catalyzed in either direction by bases, so most acetals and ketals are quite stable to bases, though they are easily hydrolyzed by acids. This reaction is therefore a useful method of protection of aldehyde or ketone functions from attack by bases. The reaction is of wide scope. Most aldehydes are easily converted to acetals.¹⁴⁷ With ketones the process is more difficult, presumably for steric reasons, and the reaction often fails, though many ketals, especially from cyclic ketones, have been made in this manner.¹⁴⁸ Many functional groups may be present without being affected. 1,2-Glycols and 1,3-glycols form cyclic acetals and ketals (1,3-dioxolanes)¹⁴⁹

and 1,3-dioxanes,¹⁵⁰ respectively), and these are often used to protect aldehydes and ketones. Chiral dioxolanes have been prepared from chiral diols.¹⁵¹ Dioxolanes have been prepared from ketones in ionic liquids.¹⁵² Ketones are converted with dimethyl ketals by electrolysis with NaBr in methanol.¹⁵³

Intramolecular reactions are possible in which a keto diol or an aldehyde diol generates a bicyclic ketal or acetal. Fused ring [2.2.0] ketals have been prepared in this manner.¹⁵⁴

The mechanism, which involves initial formation of a *hemiacetal*,¹⁵⁵ is the reverse of that given for acetal hydrolysis:

In a study of the acid-catalyzed formation of the hemiacetal, Grunwald showed¹⁵⁶ that the data best fit a mechanism in which the three steps shown here are actually all concerted; that is, the reaction is simultaneously catalyzed by acid and base, with water acting as the base.¹⁵⁷

If the original aldehyde or ketone has an α hydrogen, it is possible for water to split out in that way and enol ethers can be prepared in this manner:

¹⁵⁶Grunwald, E. *J. Am. Chem. Soc.* **1985**, *107*, 4715.

¹⁵⁷Grunwald also studied the mechanism of the base-catalyzed formation of the hemiacetal, and found it to be the same as that of base-catalyzed hydration (**16-1**, mechanism a): Grunwald, E. *J. Am. Chem. Soc.* **1985**, *107*, 4710. See also, Sørensen, P.E.; Pedersen, K.J.; Pedersen, P.R.; Kanagasabapathy, V.M.; McClelland, R.A. *J. Am. Chem. Soc.* **1988**, *110*, 5118; Leussing, D.L. *J. Org. Chem.* **1990**, *55*, 666.

Similarly, treatment with an anhydride and a catalyst can give an enol ester (see **16-6**).¹⁵⁸

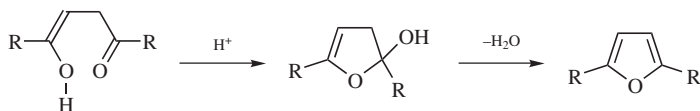

Hemiacetals themselves are no more stable than the corresponding hydrates (**16-1**). As with hydrates, hemiacetals of cyclopropanones¹⁵⁹ and of polychloro and polyfluoro aldehydes and ketones may be quite stable.

When acetals or ketals are treated with an alcohol of higher molecular weight than the one already there, it is possible to get a transacetalation (see **10-13**). In another type of transacetalation, aldehydes or ketones can be converted to acetals or ketals by treatment with another acetal or ketal or with an ortho ester,¹⁶⁰ in the presence of an acid catalyst (shown for an ortho ester):

This method is especially useful for the conversion of ketones to ketals, since the direct reaction of a ketone with an alcohol often gives poor results. In another method, the substrate is treated with an alkoxy silane ROSiMe_3 in the presence of trimethylsilyl trifluoromethanesulfonate.¹⁶¹

1,4-Diketones give furans when treated with acids. This is actually an example of an intramolecular addition of an alcohol to a ketone, since it is the enol form that adds:

Similarly, 1,5-diketones give pyrans. Conjugated 1,4-diketones, such as 1,4-diphenylbut-2-en-1,4-dione is converted to 2,5-diphenylfuran with formic acid, 5% Pd/C, PEG-200, and a sulfuric acid catalyst with microwave irradiation.¹⁶² Formic acid reacts with alcohols to give orthoformates. Note that alkynyl ketones are converted to furans with palladium (II) acetate.¹⁶³

Aldehydes and ketones can be converted to ethers by treatment with an alcohol and triethylsilane in the presence of a strong acid¹⁸¹ or by hydrogenation in alcoholic acid in the presence of platinum oxide.¹⁸² The process can formally be regarded as addition of ROH to give a hemiacetal, $RR'C(OH)OR^2$, followed by reduction of the OH. In this respect, it is similar to **16-17**. The reaction of an aldehyde with $BuOSiHMe_2$ and a Me_3SiI catalyst gives the corresponding butyl alkyl ether.¹⁸³ In a similar reaction, ketones can be converted to carboxylic esters (reductive acylation of ketones) by treatment with an acyl chloride and triphenyltin hydride.¹⁸⁴

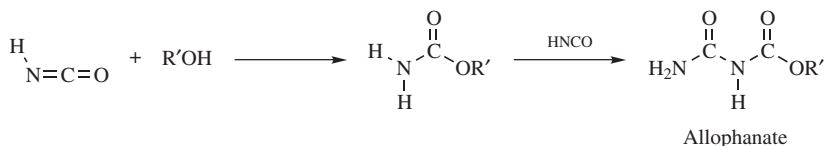

Ethers have also been prepared by the reductive dimerization of two molecules of an aldehyde or ketone (e.g., cyclohexanone \rightarrow dicyclohexyl ether). This was accomplished by treatment of the substrate with a trialkylsilane and a catalyst.¹⁸⁵

16-8 The Addition of Alcohols to Isocyanates

N-Hydro-*C*-alkoxy-addition

Carbamates (substituted urethanes) are prepared when isocyanates are treated with alcohols. This is an excellent reaction, of wide scope, and gives good yields. Isocyanic acid $HNCO$ gives unsubstituted carbamates. Addition of a second equivalent of $HNCO$ gives *allophanates*.

The isocyanate can be generated *in situ* by the reaction of an amine and oxalyl chloride, and subsequent reaction with HCl and then an alcohol gives the carbamate.¹⁸⁶ Polyurethanes are made by combining compounds with two NCO groups with

compounds containing two OH groups. Cyclic carbamates, such as 1,3-oxazine-2-ones, are generated by the reaction of an isocyanate with an oxetane, in the presence of a palladium catalyst.¹⁸⁷ Isothiocyanates similarly give thiocarbamates¹⁸⁸ RNHCSOR', though they react slower than the corresponding isocyanates. Isocyanates react with LiAlHSeH and then iodomethane to give the corresponding selenocarbonate (RNHCOSeMe).¹⁸⁹

The details of the mechanism are poorly understood,¹⁹⁰ though the oxygen of the alcohol is certainly attacking the carbon of the isocyanate. Hydrogen bonding complicates the kinetic picture.¹⁹¹ The addition of ROH to isocyanates can also be catalyzed by metallic compounds,¹⁹² by light,¹⁹³ or, for tertiary ROH, by lithium alkoxides¹⁹⁴ or *n*-butyllithium.¹⁹⁵

OS I, 140; V, 162; VI, 95, 226, 788, 795.

16-9 Alcoholysis of Nitriles

Alkoxy,oxo-de-nitrilo-tersubstitution

The addition of dry HCl to a mixture of a nitrile and an alcohol in the absence of water leads to the hydrochloride salt of an imino ester (imino esters are also called imidates and imino ethers). This reaction is called the *Pinner synthesis*.¹⁹⁶ The salt can be converted to the free imino ester by treatment with a weak base such as sodium bicarbonate, or it can be hydrolyzed with water and an acid catalyst to the corresponding carboxylic ester. If the latter is desired, water may be present from the beginning, in which case aq. HCl can be used and the need for gaseous HCl is eliminated. Imino esters can also be prepared from nitriles with basic catalysts.¹⁹⁷

¹⁹⁷Schaefer, F.C.; Peters, G.A. *J. Org. Chem.* **1961**, *26*, 412.

This reaction is of broad scope and is good for aliphatic, aromatic, and heterocyclic R and for nitriles with oxygen-containing functional groups. The application of the reaction to nitriles containing a carboxyl group constitutes a good method for the synthesis of mono esters of dicarboxylic acids with the desired group esterified and with no diester or diacid present.

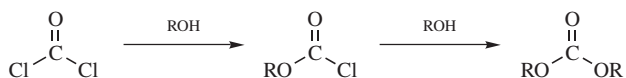

Cyanogen chloride reacts with alcohols in the presence of an acid catalyst, such as dry HCl or AlCl₃, to give carbamates:¹⁹⁸

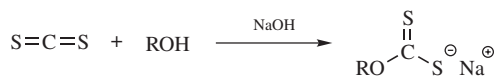

ROH can also be added to nitriles in another manner (**16-91**).
OS I, 5, 270; II, 284, 310; IV, 645; VI, 507; VIII, 415.

16-10 The Formation of Carbonates and Xanthates

Di-C-alkoxy-addition; S-Metallo-C-alkoxy-addition

The reaction of phosgene with an alcohol generates a haloformic esters, and reaction with a second equivalent of alcohol gives a carbonate. This reaction is related to the acyl addition reactions of acyl chlorides in Reaction **16-98**. An important example is the preparation of carbobenzoxy chloride (PhCH₂OCOCI) from phosgene and benzyl alcohol. This compound is widely used for protection of amino groups during peptide synthesis. When an alcohol reacts with certain alkyl halides (e.g., benzyl chloride) and carbon dioxide, in the presence of Cs₂CO₃ and tetrabutylammonium iodide, a mixed carbonate is formed.¹⁹⁹

The addition of alcohols to carbon disulfide in the presence of a base produces xanthates.²⁰⁰ The base is often HO⁻, but in some cases better results can be obtained by using methylsulfinyl carbanion MeSOCH₂⁻.²⁰¹ If an alkyl halide RX is present, the xanthate ester ROCSSR' can be produced directly. In a similar manner, alkoxide ions add to CO₂ to give carbonate ester salts (ROCOO⁻).

16-11 The Addition of H₂S and Thiols to Carbonyl Compounds

O-Hydro-*C*-mercapto-addition²⁰²

The addition of H₂S to an aldehyde or ketone can result in a variety of products. The most usual product is the trithiane **16**.²⁰³ *gem*-Dithiols (**15**) are much more stable than the corresponding hydrates or α -hydroxy thiols.²⁰⁴ They have been prepared by the treatment of ketones with H₂S under pressure²⁰⁵ and under mild conditions with HCl as a catalyst.²⁰⁶ Thiols add to aldehydes and ketones to give hemimercaptals, CH(OH)SR and dithioacetals, CH(SR)₂ (**16-5**). α -Hydroxy thiols (**13**) can be prepared from polychloro and polyfluoro aldehydes and ketones.²⁰⁷ Apparently **13** are stable only when prepared from these compounds, and not even for all of them.

Thioketones² (**14**) can be prepared from certain ketones, such as diaryl ketones, by treatment with H₂S and an acid catalyst, usually HCl. They are often unstable and usually trimerize (to **16**) or react with air. Thioaldehydes²⁰⁸ are even less stable and simple ones²⁰⁹ apparently have never been isolated, though *t*-BuCHS has been prepared in

²⁰²This name applies to formation of **13**. Names for formation of **14–16**, are, respectively, thioxo-de-oxo-bisubstitution, dimercapto-de-oxo-bisubstitution, and carbonyl-trithiane transformation.

like acetals, are stable in the presence of bases, except that a strong base can remove the aldehyde proton, if there is one²³⁰ (see 10-71).

The reaction of aldehydes or ketones with thiols, usually with a Lewis acid catalyst, leads to dithioacetals²³¹ or dithioketals. The most common catalyst used is probably boron trifluoride etherate ($\text{BF}_3 \cdot \text{OEt}_2$).²³² Similarly reactions that use 1,2-ethanedithiol or 1,3-propanedithiol lead to 1,3-dithiolanes, such as **18**²³³ or 1,3-dithianes.²³⁴ Dithioacetals can also be prepared from aldehydes or ketones by treatment with thiols in the presence of TiCl_4 ,²³⁵ SiCl_4 ,²³⁶ LiBF_4 ,²³⁷ $\text{Al}(\text{OTf})_3$,²³⁸ with a disulfide RSSR ($\text{R} = \text{alkyl or aryl}$),²³⁹ or with methylthiotrimethylsilane (MeSSiMe_3).²⁴⁰

Dithioacetals and dithioketals are used as protecting groups for aldehydes and ketones, and after subsequent reactions involving the R or R' group, the protecting group can then be removed.²⁴¹ There are a variety of reagents that convert these compounds back to the carbonyl.²⁴² Simple hydrolysis is the most common method for converting thiocarbonyls to carbonyls. Stirring thioketones with 4-nitrobenzaldehyde and a catalytic amount of TMSOTf gives the ketone.²⁴³ The reaction of a thioketone and Clayfen with microwave irradiation give the ketone.²⁴⁴ Thioamides

are converted to amides with Caro's acid on SiO_2 .²⁴⁵ Lewis acids, such as aluminum chloride (AlCl_3) and mercuric salts, are common reagents and their use is referred to as the Corey–Seebach procedure.²⁴⁶ Other reagents include $\text{BF}_3 \cdot \text{OEt}_2$ in aq. THF containing mercuric oxide (HgO),²⁴⁷ NBS,²⁴⁸ iodine in DMSO,²⁴⁹ ceric ammonium nitrate, $\text{Ce}(\text{NH}_4)_2(\text{NO}_3)_6$,²⁵⁰ iodomethane in aqueous media,²⁵¹ Clayfen with microwave irradiation,²⁵² $\text{PhI}(\text{OAc})_2$ in aqueous acetone,²⁵³ and NCS with silver nitrate in aqueous acetonitrile.²⁵⁴ When aldehydes and ketones react with mercapto-alcohols, mixed acetals or ketals are formed. The use of 2-mercaptoethanol ($\text{HSCH}_2\text{CH}_2\text{OH}$), for example, leads to an oxathiolane²⁵⁵ and 3-mercaptopropanol ($\text{HSCH}_2\text{CH}_2\text{CH}_2\text{OH}$) leads to an oxathiane. Alternatively, the dithioketal can be desulfurized with Raney nickel (**14-27**), giving the overall conversion $\text{C}=\text{O} \rightarrow \text{CH}_2$.

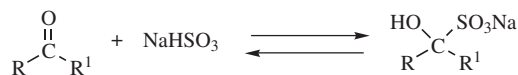

If an aldehyde or ketone possesses an α hydrogen, it can be converted to the corresponding enol thioether (**19**) by treatment with a thiol in the presence of TiCl_4 .²⁵⁶ Aldehydes and ketones have been converted to sulfides by treatment with thiols and pyridine–borane, $\text{RCOR}' + \text{R}^2\text{SH} \rightarrow \text{RR}'\text{CHSR}^2$,²⁵⁷ in a reductive alkylation reaction, analogous to **16-7**.

Bisulfite addition products are formed from aldehydes, methyl ketones, cyclic ketones (generally seven-membered and smaller rings), α -keto esters, and isocyanates, upon treatment with sodium bisulfite. Most other ketones do not undergo the reaction, probably for steric reasons. The reaction is reversible (by treatment of the addition product with either acid or base^{258,259}) and is useful for the purification of the starting compounds, since the addition products are soluble in water and many of the impurities are not.²⁶⁰

16-13 The Addition of Amines to Aldehydes and Ketones

Alkylimino-de-oxo-bisubstitution

The addition of ammonia²⁶¹ to aldehydes or ketones does not generally give useful products. According to the pattern followed by analogous nucleophiles, the initial products would be expected to be *hemiaminals*,²⁶² but these compounds are generally unstable. Most imines with a hydrogen on the nitrogen spontaneously polymerize.²⁶³ In the presence of an oxidizing agent, such as MnO_2 (see **19-3**), primary alcohols can be converted to imines.²⁶⁴

In contrast to ammonia, primary, secondary, and tertiary amines can add to aldehydes²⁶⁵ and ketones to give different kinds of products. Primary amines give imines²⁶⁶ and secondary amines gives enamines (**10-69**). This section will focus on imines. Reduction of ω -azido ketones leads to the amino-ketones, which cyclizes to form a 2-substituted pyrroline.²⁶⁷ Reduction of nitro-ketones in the presence

²⁵⁸For cleavage with ion-exchange resins, see Khusid, A.Kh.; Chizhova, N.V. *J. Org. Chem. USSR* **1985**, 21, 37.

²⁵⁹For a discussion of the mechanism, see Young, P.R.; Jencks, W.P. *J. Am. Chem. Soc.* **1978**, 100, 1228.

²⁶⁰The reaction has also been used to protect an aldehyde group in the presence of a keto group: Chihara, T.; Wakabayashi, T.; Taya, K. *Chem. Lett.* **1981**, 1657.

²⁶¹For a review of this reagent in organic synthesis, see Jeyaraman, R., in Pizey, J.S. *Synthetic Reagents*, Vol. 5, Wiley, NY, **1983**, pp. 9–83.

²⁶²These compounds have been detected by ¹³C NMR: Chudek, J.A.; Foster, R.; Young, D. *J. Chem. Soc. Perkin Trans. 2* **1985**, 1285.

²⁶³Methanimine $\text{CH}_2=\text{NH}$ is stable in solution for several hours at -95°C , but rapidly decomposes at -80°C : Braillon, B.; Lasne, M.C.; Ripoll, J.L.; Denis, J.M. *Nouv. J. Chim.*, **1982**, 6, 121. See also, Bock, H.; Dammel, R. *Chem. Ber.* **1987**, 120, 1961.

of ruthenium compounds and CO also leads to 1-substituted pyrrolines.²⁶⁸ In contrast to imines in which the nitrogen is attached to a hydrogen, these imines are stable enough for isolation. However, in some cases, especially with simple R groups, they rapidly decompose or polymerize unless there is at least one aryl group on the nitrogen or the carbon. When there is an aryl group, the compounds are quite stable. They are usually called *Schiff bases*, and this reaction is the best way to prepare them.²⁶⁹ The reaction is straightforward and proceeds in high yields. Even sterically hindered imines can be prepared.²⁷⁰ Both imines and enamines (see below) have been prepared on clay with microwave irradiation.²⁷¹ The initial *N*-substituted hemiaminals²⁷² lose water to give the stable Schiff bases:

In general, ketones react more slowly than aldehydes, and higher temperatures and longer reaction times are often required.²⁷³ In addition, the equilibrium must often be shifted, usually by removal of the water, either azeotropically by distillation, or with a drying agent, such as TiCl₄,²⁷⁴ or with a molecular sieve.²⁷⁵ Imines have been formed from aldehydes and amines in an ionic liquid.²⁷⁶

The reaction is often used to effect ring closure.²⁷⁷ The *Friedländer quinoline synthesis*²⁷⁸ is an example where ortho alkenyl aniline derivatives give the quinoline, **20**.²⁷⁹ The alkene derivative can be prepared *in situ* from an aldehyde and a suitably functionalized ylid.²⁸⁰

Pyrylium ions react with ammonia or primary amines to give pyridinium ions²⁸¹ (see p. 498). Primary amines react with 1,4-diketones, with microwave irradiation, to give *N*-substituted pyrroles.²⁸² Similar reactions in the presence of Montmorillonite KSF²⁸³ or by simply heating the components with tosic acid²⁸⁴ have been reported.

As mentioned, the reaction of secondary amines with ketones leads to enamines (**10-69**). When secondary amines are added to aldehydes or ketones, the initially formed *N,N*-disubstituted hemiaminals (**21**) cannot lose water in the same way, and in some cases it is possible to isolate them.²⁸⁵ However, they are generally unstable, and under the reaction conditions usually react further. If no α hydrogen is present, **10** is converted to

the more stable *aminal* (**22**).²⁸⁶ However, if an α hydrogen is present, water (from **21**) or RNH₂ (from **22**) can be lost in that direction to give an enamine, **24**.²⁸⁷ This is the most common method²⁸⁸ for the preparation of enamines and usually takes place when an aldehyde or ketone containing an α hydrogen is treated with a secondary amine. The water is usually removed azeotropically or with a drying agent,²⁸⁹ but molecular sieves can also be used.²⁹⁰ Silyl carbamates, such as Me₂NCO₂SiMe₃, have been used to convert ketones to enamines.²⁹¹ Stable primary enamines have also been prepared.²⁹² Enamino-ketones have been prepared from diketones and secondary amines using low molecular weight amines in water,²⁹³ or using microwave irradiation on silica gel.²⁹⁴ Secondary amine perchlorates react

16-14 The Addition of Hydrazine Derivatives to Carbonyl Compounds

Hydrazono-de-oxo-bisubstitution

The product of condensation of a hydrazine and an aldehyde or ketone is called a *hydrazone*. Hydrazine itself gives hydrazones only with aryl ketones. With other aldehydes and ketones, either no useful product can be isolated, or the remaining NH₂ group condenses with a second equivalent of carbonyl compound to give an *azine*. This type of product is especially important for aromatic aldehydes:

However, in some cases azines can be converted to hydrazones by treatment with excess hydrazine and NaOH.³⁰⁰ Arylhydrazines, especially phenyl, *p*-nitrophenyl, and 2,4-dinitrophenyl,³⁰¹ are used much more often and give the corresponding hydrazones with most aldehydes and ketones.³⁰² Since these are usually solids, they make excellent derivatives and are commonly employed for this purpose. Cyclic hydrazones are also known,³⁰³ as are conjugated hydrazones.³⁰⁴ Azides react

with *N,N*-dimethylhydrazine and ferric chloride to give the *N,N*-dimethylhydrazone.³⁰⁵ Alkenes react with CO/H₂, phenylhydrazine and a diphosphine catalyst to give a regioisomeric mixture of phenylhydrazones that favored “anti-Markovnikov” addition.³⁰⁶ Oximes are converted to hydrazones with water and hydrazine in refluxing ethanol.³⁰⁷

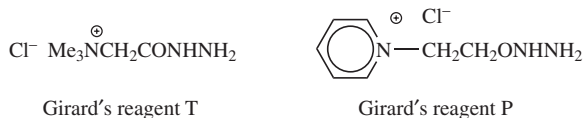

α -Hydroxy aldehydes and ketones and α -dicarbonyl compounds give *osazones*, in which two adjacent carbons have carbon–nitrogen double bonds:

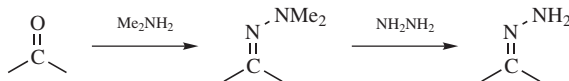

Osazones are particularly important in carbohydrate chemistry. In contrast to this behavior, β -diketones and β -keto esters give *pyrazoles* and *pyrazolones*, respectively (illustrated for β -keto esters):

Other hydrazine derivatives frequently used to prepare the corresponding hydrazone are semicarbazide NH₂NHCONH₂, in which case the hydrazone is called a semicarbazone, and *Girard's reagents T and P*, in which case the hydrazone is water soluble because of the ionic group. Girard's reagents are often used for purification of carbonyl compounds.³⁰⁸

Simple *N*-unsubstituted hydrazones can be obtained by an exchange reaction. The *N,N*-dimethylhydrazone is prepared first, and then treated with hydrazine:³⁰⁹

No azines are formed under these conditions.

16-15 The Formation of Oximes

Hydroxyimino-de-oxo-bisubstitution

In a reaction very much like 16-14, oximes can be prepared by the addition of hydroxylamine to aldehydes or ketones. Derivatives of hydroxylamine [e.g., $\text{H}_2\text{NOSO}_3\text{H}$ and $\text{HON}(\text{SO}_3\text{Na})_2$] have also been used. For hindered ketones, such as hexamethylacetone, high pressures (as high as 10,000 atm) may be necessary.³¹⁰ The reaction of hydroxylamine with unsymmetrical ketones or with aldehydes leads to a mixture of (*E*)- and (*Z*)-isomers. For aromatic aldehydes, heating with K_2CO_3 led to the (*E*)- isomer whereas heating with CuSO_4 gave the (*Z*)-hydroxylamine.³¹¹ Hydroxylamines react with ketones in ionic liquids³¹² and on silica gel.³¹³

It has been shown³¹⁴ that the rate of formation of oximes is at a maximum at a pH that depends on the substrate but is usually ~ 4 , and that the rate decreases as the pH is either raised or lowered from this point. We have previously seen (p. 1256) that bell-shaped curves like this are often caused by changes in the rate-determining step. In this case, at low pH values step 2 is rapid (because it is acid-catalyzed), and step 1

is slow (and rate-determining), because under these acidic conditions most of the NH_2OH molecules have been converted to the conjugate NH_3OH^+ ions, which cannot attack the substrate. As the pH is slowly increased, the fraction of free NH_2OH molecules increases and consequently so does the reaction rate, until the maximum rate is reached at $\sim \text{pH } 4$. As the rising pH has been causing an increase in the rate of step 1, it has also been causing a *decrease* in the rate of the acid-catalyzed step 2, although this latter process has not affected the overall rate since step 2 was still faster than step 1. However, when the pH goes above ~ 4 , step 2 becomes rate-determining, and although the rate of step 1 is still increasing (as it will until essentially all the NH_2OH is unprotonated), it is now

step 2 that determines the rate, and this step is slowed by the decrease in acid concentration. Thus the overall rate decreases as the pH rises beyond ~ 4 . It is likely that similar considerations apply to the reaction of aldehydes and ketones with amines, hydrazines, and other nitrogen nucleophiles.³¹⁵ There is evidence that when the nucleophile is 2-methylthiosemicarbazide, there is a second change in the rate-determining step: above pH ~ 10 basic catalysis of step 2 has increased the rate of this step to the point where step 1 is again rate determining.³¹⁶ Still a third change in the rate-determining step has been found at about pH 1, showing that at least in some cases step 1 actually consists of two steps: formation of a zwitterion, for example,

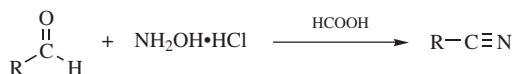

in the case shown above, and conversion of this to **25**.³¹⁷ The intermediate **25** has been detected by nmr in the reaction between NH_2OH and acetaldehyde.³¹⁸

In another type of process, oximes can be obtained by passing a mixture of ketone vapor, NH_3 , and O_2 over a silica-gel catalyst.³¹⁹ Ketones can also be converted to oximes by treatment with other oximes, in a transoximation reaction.³²⁰

16-16 The Conversion of Aldehydes to Nitriles

Nitrilo-de-hydro,oxo-tersubstitution

Aldehydes can be converted to nitriles in one step by treatment with hydroxylamine hydrochloride and either formic acid,³²¹ $\text{NaHSO}_4\cdot\text{SiO}_2$ with microwave irradiation,³²² or $(\text{Bu}_4\text{N})_2\text{S}_2\text{O}_8$ with $\text{Cu}(\text{HCO}_2)\cdot\text{Ni}(\text{COOH})_2$ and aq. KOH .³²³ Heating in NMP is also effective with aryl aldehydes³²⁴ and heating on dry alumina with

aliphatic aldehyde.³²⁵ The reaction is a combination of **16-15** and **17-29**. Direct nitrile formation has also been accomplished with certain derivatives of NH_2OH , notably, $\text{NH}_2\text{OSO}_2\text{OH}$.³²⁶ Treatment with hydroxylamine and NaI ³²⁷ or certain carbonates³²⁸ also converts aldehydes to the nitrile. Another method involves treatment with hydrazoic acid, though the Schmidt reaction (**18-16**) may compete.³²⁹ Aromatic aldehydes have been converted to nitriles in good yield with $\text{NH}_2\text{OH}/\text{HCOOH}$ on silica gel.³³⁰ Microwave irradiation has been used with $\text{NH}_2\text{OH}\cdot\text{HCl}$ and another reagent, which includes phthalic anhydride,³³¹ $\text{Bu}_2\text{SnO}\cdot\text{Al}_2\text{O}_3$,³³² or $\text{H}-\text{Y}$ zeolite.³³³ Other reagents include *N*-phenylurea with tosic acid,³³⁴ MnO_2 and ammonia,³³⁵ I_2 with aqueous ammonia,³³⁶ dimethylhydrazine followed by dimethyl sulfoxide,³³⁷ trimethylsilyl azide,³³⁸ and with hydroxylamine hydrochloride, MgSO_4 , and TsOH .³³⁹ The reaction of a conjugated aldehyde with ammonia, CuCl and 50% H_2O_2 gave the conjugated nitrile.³⁴⁰ Benzylic alcohols can be oxidized in the presence of ammonia to give the nitrile.³⁴¹ Trichloroisocyanuric acid with a catalytic amount of TEMPO (p. 274) converts aldehydes to nitriles at 0°C in dichloromethane.³⁴²

On treatment with 2 equivalents of dimethylaluminum amide Me_2AlNH_2 , carboxylic esters can be converted to nitriles: $\text{RCOOR}' \rightarrow \text{RCN}$.³⁴³ This is very likely a combination of **16-75** and **17-30**. See also, **19-5**.

When an aldehyde or a ketone is treated with ammonia or a primary or secondary amine in the presence of hydrogen and a hydrogenation catalyst (heterogeneous or homogeneous),³⁴⁴ *reductive alkylation* of ammonia or the amine (or *reductive amination* of the carbonyl compound) takes place.³⁴⁵ The reaction can formally be regarded as occurring in the following manner (shown for a primary amine), which probably does correspond to the actual sequence of steps:³⁴⁶ In this regard, the reaction of an aldehyde with an amine to give an iminium salt (**16-31**) can be followed in a second chemical step of reduction of the C=N unit (**19-42**) using NaBH₄ or a variety of other reagents.³⁴⁷
