Primary amines have been prepared from many aldehydes with at least five carbons and from many ketones by treatment with ammonia and a reducing agent. Smaller aldehydes are usually too reactive to permit isolation of the primary amine. Secondary amines have been prepared by both possible procedures: 2 equivalents of ammonia and 1 equivalent of aldehyde or ketone, and 1 equivalent of primary amine and 1 equivalent of carbonyl compound, the latter method being better for all but aromatic aldehydes. Tertiary amines can be prepared in three ways, but the method is seldom carried out with 3 equivalents of ammonia and 1 equivalent of carbonyl compound. Much more often they are prepared from primary or secondary amines.³⁴⁸ When the reagent is ammonia, it is possible for the initial product to react again and for this product to react again, so that secondary and tertiary amines are usually obtained as side products. Similarly, primary amines give tertiary as well as secondary amines. In order to minimize this, the aldehyde or ketone is treated with an excess of ammonia or primary amine (unless of course the higher amine is desired).

For ammonia and primary amines there are two possible pathways, but when secondary amines are involved, only the hydrogenolysis pathway is possible. The reaction is compatible with amino acids, giving the *N*-alkylated amino acid.³⁴⁹

Other reducing agents³⁵⁰ can be used instead of hydrogen and a catalyst, among them zinc and HCl, B₁₀H₁₄³⁵¹ or B₁₀H₁₄ with Pd/C,³⁵² a picolinyl borane complex in acetic acid–methanol,³⁵³ PhSiH₃ with 2% Bu₂SnCl₂,³⁵⁴ and polymethylhydrosiloxane.³⁵⁵ Several hydride reducing agents can be used, including NaBH₄,³⁵⁶ sodium borohydride with Ti(OiPr)₄,³⁵⁷ or NiCl₂,³⁵⁸ NaBH₄/H₃BO₄,³⁵⁹ borohydride-exchange resin,³⁶⁰ sodium cyanoborohydride (NaBH₃CN),³⁶¹ sodium triacetoxymethylborohydride,³⁶² or a polymer-bound triethylammonium acetoxymethylborohydride.³⁶³ A Hantzsch dihydropyridine in conjunction with a scandium catalyst has been used.³⁶⁴ An interesting variation uses a benzylic alcohol in a reaction with a primary amine, and a mixture of MnO₂ and NaBH₄, giving *in situ* oxidation to the aldehyde and reductive amination to give the amine as the final product.³⁶⁵

Formic acid is commonly used for reductive amination³⁶⁶ in what is called the *Wallach reaction*. Secondary amines react with formaldehyde and NaH₂PO₃ to give the *N*-methylated tertiary amine³⁶⁷ and microwave irradiation has also been used.³⁶⁸ Conjugated aldehydes are converted to alkenyl-amines with the amine/silica gel followed by reduction with zinc borohydride.³⁶⁹ In the particular case where primary or secondary amines are reductively methylated with formaldehyde and formic acid, the method is called the *Eschweiler–Clarke procedure*. Heating with paraformaldehyde and oxalyl chloride has been used to give the same result.³⁷⁰ It is

possible to use ammonium (or amine) salts of formic acid,³⁷¹ or formamides, as a substitute for the Wallach conditions. This method is called the *Leuckart reaction*,³⁷² and in this case the products obtained are often the *N*-formyl derivatives of the amines instead of the free amines. A transition-metal catalyzed variation has been reported.³⁷³ Primary and secondary amines can be *N*-ethylated (e.g., $\text{ArNHR} \rightarrow \text{ArNREt}$) by treatment with NaBH_4 in acetic acid.³⁷⁴ Aldehydes react with aniline in the presence of Montmorillonite K10 clay and microwaves to give the amine.³⁷⁵ Tributyltin hydride is used with an ammonium salt,³⁷⁶ or $\text{Bu}_2\text{SnClH}\cdot\text{HMPA}$ with an aromatic amine,³⁷⁷ in the presence of a ketone to give the corresponding amine. Allylic silanes react with aldehydes and carbamates, in the presence of bismuth catalysts,³⁷⁸ or $\text{BF}_3\cdot\text{OEt}_2$ ³⁷⁹ to give the corresponding allylic *N*-carbamoyl derivative, and trityl perchlorate has been used for the same purpose when *N*-trimethylsilyl carbamates are employed.³⁸⁰ The reaction can be done with aromatic amines in the presence of vinyl ethers and a copper complex to give β -amino ketones.³⁸¹ Reductive amination of an aryl amine and an aryl aldehyde that contains a ortho conjugated ketone substituents gives the amine, which adds 1,4- (**15-AA**) to the α,β -unsaturated ketone unit to give a bicyclic amine.³⁸² Alternative methods of reductive alkylation have been developed. Alkylation of an imine formed *in situ* is also possible.³⁸³

Reductive alkylation has also been carried out on nitro, nitroso, azo, and other compounds that are reduced *in situ* to primary or secondary amines. Azo compounds react with aldehydes, in the presence of proline, and subsequent reduction with NaBH_4 gives the chiral hydrazine derivative.³⁸⁴

16-18 Addition of Amides to Aldehydes

Alkylamido-de-oxo-bisubstitution

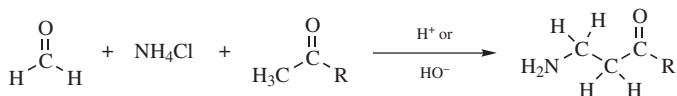

Amides can add to aldehydes in the presence of bases (so the nucleophile is actually RCONH^-) or acids to give acylated amino alcohols, which often react further to give alkylidene or arylidene bisamides.³⁸⁵ If the R' group contains an α hydrogen, water may split out.

Sulfonamides add to aldehydes to give the *N*-sulfonyl imine. Benzaldehyde reacts with TsNH_2 , for example, at 160°C in the presence of $\text{Si}(\text{OEt})_4$,³⁸⁶ with trifluoroacetic anhydride (TFAA) in refluxing dichloromethane,³⁸⁷ or with TiCl_4 in refluxing dichloroethane,³⁸⁸ to give the *N*-tosylimine, $\text{Ts}-\text{N}=\text{CHPh}$. In a similar manner, the reaction of $\text{ToISO}_2\text{Na} + \text{PhSO}_2\text{Na}$ with an aldehyde in aqueous formic acid gives the *N*-phenylsulfonyl imine.³⁸⁹ The reaction of an aldehyde with $\text{Ph}_3\text{P}=\text{NTs}$ and a ruthenium catalyst gives the *N*-tosyl imine.³⁹⁰ Reaction of aldehydes with $\text{LiAl}(\text{NHBn})_4$ also give the corresponding *N*-benzylimine.³⁹¹

16-19 The Mannich Reaction

Acyl,amino-de-oxo-bisubstitution, and so on

In the *Mannich reaction*, formaldehyde (or sometimes another aldehyde) is condensed with ammonia, in the form of its salt, and a compound containing an active hydrogen.³⁹² This can formally be considered as an addition of ammonia to give

³⁸⁵For reviews, see Challis, B.C.; Challis, J.A. in Zabicky, J. *The Chemistry of Amides*, Wiley, NY, **1970**, pp. 754–759; Zaugg, H.E.; Martin, W.B. *Org. React.* **1965**, *14*, 52, 91–95, 104–112. For a discussion, see Gilbert, E.E. *Synthesis* **1972**, 30.

$\text{H}_2\text{NCH}_2\text{OH}$, followed by a nucleophilic substitution. Instead of ammonia, the reaction can be carried out with salts of primary or secondary amines,³⁹³ or with amides,³⁹⁴ in which cases the product is substituted on the nitrogen with R, R₂, and RCO, respectively. The imine can be generated *in situ*, and the reaction of a ketone, formaldehyde, and diethylamine with microwave irradiation gave the Mannich product, a β -amino ketone.³⁹⁵ Arylamines do not normally give the reaction. Hydrazines can be used.³⁹⁶ The product is referred to as a *Mannich base*. Many active hydrogen compounds give the reaction, including ketones and aldehydes, esters, nitroalkanes,³⁹⁷ and nitriles as well as ortho-carbons of phenols, the carbon of terminal alkynes, the oxygen of alcohols and the sulfur of thiols.³⁹⁸ Vinylogous Mannich reactions are known.³⁹⁹

The Mannich base can react further in three ways. If it is a primary or secondary amine, it may condense with one or two additional molecules of aldehyde and active compound, for example,

If the active hydrogen compound has two or three active hydrogens, the Mannich base may condense with one or two additional molecules of aldehyde and ammonia or amine, for example,

Another further reaction consists of condensation of the Mannich base with excess formaldehyde:

Sometimes it is possible to obtain these products of further condensation as the main products of the reaction. At other times they are side products.

When the Mannich base contains an amino group β to a carbonyl (and it usually does), ammonia is easily eliminated. This is a route to α,β -unsaturated aldehydes, ketones, esters, and so on.

Another type of pre-formed reagent (**28**) has been used to carry out diastereoselective Mannich reactions. The lithium salts **27** are treated with TiCl_4 to give **28**, which is then treated with the enolate of a ketone.⁴⁰⁷ The palladium catalyzed Mannich reaction of enol ethers to imines is also known.⁴⁰⁸ The reaction of silyl enol ethers and imines is catalyzed by HBF_4 in aqueous methanol.⁴⁰⁹ Similarly, silyl enol ethers react with aldehydes and aniline in the presence of InCl_3 to give the β -amino ketone.⁴¹⁰ Imines react on Montmorillonite K10 clay and microwave irradiation gives β -amino esters.⁴¹¹ Enol ethers react similarly in the presence of $\text{Yb}(\text{OTf})_3$.⁴¹²

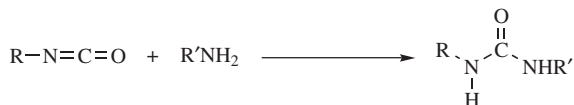

Enantioselective Mannich reactions are known.⁴¹³ The most common method uses a chiral catalyst, including proline,⁴¹⁴ proline derivatives or proline analogs.⁴¹⁵ Chiral diamine⁴¹⁶ or phosphine-imine⁴¹⁷ ligands have been used. Chiral auxiliaries on the carbonyl fragment can be used.⁴¹⁸ Chiral imines, in the form of chiral hydrazones have been used with silyl enol ethers and a scandium catalyst.⁴¹⁹ Chiral amine react with aldehydes, with silyl enol ethers and an InCl_3 catalyst in ionic liquids, to give the Mannich product with good enantioselectivity.⁴²⁰

Ammonia and primary and secondary amines can be added to isocyanates⁴²¹ to give substituted ureas.⁴²² Isothiocyanates give thioureas.⁴²³ This is an excellent method for the preparation of ureas and thioureas, and these compounds are often used as derivatives for primary and secondary amines. Isocyanic acid (HNCO) also gives the reaction; usually its salts (e.g., NaNCO) are used. Wöhler's famous synthesis of urea involved the addition of ammonia to a salt of this acid.⁴²⁴

16-21 The Addition of Ammonia or Amines to Nitriles

N-Hydro-C-amino-addition

Unsubstituted amidines (in the form of their salts) can be prepared by addition of ammonia to nitriles.⁴²⁵ Many amidines have been made in this way. Dinitriles of suitable chain length can give imidines:⁴²⁶

Primary and secondary amines can be used instead of ammonia, to give substituted amidines, but only if the nitrile contains electron-withdrawing groups; for example, Cl_3CCN gives the reaction. Ordinary nitriles do not react, and, in fact, acetonitrile is often used as a solvent in this reaction.⁴²⁷ Ordinary nitriles can be converted to amidines by treatment with an alkylchloroaluminum amide, $\text{MeAl}(\text{Cl})\text{NR}_2$ ($\text{R} = \text{H}$ or Me).⁴²⁸ The addition of ammonia to cyanamide (NH_2CN) gives guanidine, $(\text{NH}_2)_2\text{C}=\text{NH}$. Guanidines can also be formed from amines.⁴²⁹

If water is present, in the presence of a ruthenium catalyst⁴³⁰ or a platinum catalyst,⁴³¹ the addition of a primary or secondary amine to a nitrile gives an amide: $\text{RCN} + \text{R}^1\text{NHR}^2 + \text{H}_2\text{O} \rightarrow \text{RCONR}^1\text{R}^2 + \text{NH}_3$ (R^2 may be H). When benzonitrile reacts with $\text{H}_2\text{PO}_3\text{Se}^-$ in aqueous methanol, a selenoamide, $\text{PhC}=\text{Se}(\text{NH}_2)$, is formed after treatment with aq. potassium carbonate.⁴³²

16-22 The Addition of Amines to Carbon Disulfide and Carbon Dioxide

S-Metallo-C-alkylamino-addition

Salts of dithiocarbamic acid can be prepared by the addition of primary or secondary amines to carbon disulfide.⁴³³ This reaction is similar to **16-10**. Hydrogen sulfide can be eliminated from the product, directly or indirectly, to give isothiocyanates (RNCS). Isothiocyanates can be obtained directly by the reaction of primary amines and CS_2 in pyridine in the presence of dicyclohexylcarbodiimide.⁴³⁴ Aniline derivatives react with CS_2 and NaOH , and then ethyl chloroformate to give the aryl isothiocyanate.⁴³⁵ In the presence of diphenyl phosphite and pyridine, primary amines add to CO_2 and to CS_2 to give, respectively, symmetrically substituted ureas and thioureas.⁴³⁶ Isoselenoureas, $\text{R}_2\text{NC}(=\text{NR}^1)\text{SeR}^2$, can also be formed.⁴³⁷

16-23 The Formation of *gem*-Dihalides from Aldehydes and Ketones

Dihalo-de-oxo-bisubstitution

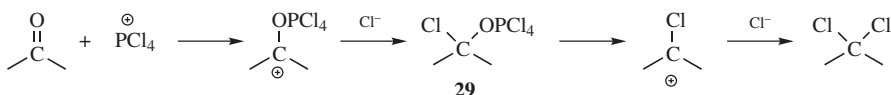

Aliphatic aldehydes and ketones can be converted to *gem*-dichlorides⁴³⁸ by treatment with PCl₅. The reaction fails for perhalo ketones.⁴³⁹ If the aldehyde or ketone has an α hydrogen, elimination of HCl may follow and a vinylic chloride is a frequent side product:⁴⁴⁰

or even the main product.⁴⁴¹ The PBr₅ does not give good yields of *gem*-dibromides,⁴⁴² but these can be obtained from aldehydes, by the use of Br₂ and triphenyl phosphite.⁴⁴³ *gem*-Dichlorides can be prepared by reacting an aldehyde with BiCl₃.⁴⁴⁴

The mechanism of *gem*-dichloride formation involves initial attack on PCl₄⁺ (which is present in solid PCl₅) at the oxygen, followed by addition of Cl⁻ to the carbon:⁴⁴⁵

This chloride ion may come from PCl₆⁻ (which is also present in solid PCl₅). There follows a two-step S_N1 process. Alternatively, **29** can be converted to the product without going through the chlorocarbocation, by an S_Ni process.

This reaction has sometimes been performed on carboxylic esters, though these compounds very seldom undergo any addition to the C=O bond. An example is the conversion of F₃CCOOPh to F₃CCCl₂OPh.⁴⁴⁶ However, formates commonly give the reaction.

Many aldehydes and ketones have been converted to *gem*-difluoro compounds with sulfur tetrafluoride SF₄,⁴⁴⁷ including quinones, which give 1,1,4,4-tetrafluorocyclohexadiene derivatives. With ketones, yields can be raised and the reaction temperature lowered, by the addition of anhydrous HF.⁴⁴⁸ Carboxylic acids, acyl chlorides, and amides react with SF₄ to give 1,1,1-trifluorides. In these cases the first product is the acyl fluoride, which then undergoes the *gem*-difluorination reaction:

The acyl fluoride can be isolated. Carboxylic esters also give trifluorides, but more vigorous conditions are required. In this case, the carbonyl group of the ester is attacked first, and RCF₂OR' can be isolated from RCOOR'⁴⁴⁹ and then converted to the trifluoride. Anhydrides can react in either manner. Both types of intermediate are isolable under the right conditions and SF₄ even converts carbon dioxide to CF₄. A disadvantage of reactions with SF₄ is that they require a pressure vessel lined with stainless steel. Selenium tetrafluoride SeF₄ gives similar reactions, but atmospheric pressure and ordinary glassware can be used.⁴⁵⁰ Another reagent that is often used to convert aldehydes and ketones to *gem*-difluorides is the commercially available diethylaminosulfur trifluoride (DAST, Et₂NSF₃), and CF₂Br₂ in the presence of zinc.⁴⁵¹ The mechanism with SF₄ is probably similar in general nature, if not in specific detail, to that with PCl₅.

Treatment with hydrazine to give the hydrazone, and then CuBr₂/*t*-BuOLi, generated the *gem*-dibromide.⁴⁵² Oximes gives *gem*-dichlorides upon treatment with chlorine and BF₃·OEt₂, and then HCl.⁴⁵³ Some dithianes can be converted to *gem*-difluorides with a mixture of fluorine and iodine in acetonitrile.⁴⁵⁴ Oximes give *gem*-difluorides with NO⁺BF₄⁻ and pyridinium polyhydrogen fluoride.⁴⁵⁵

In a related process, α -halo ethers can be prepared by treatment of aldehydes and ketones with an alcohol and HX. The reaction is applicable to aliphatic aldehydes and ketones and to primary and secondary alcohols. The addition of HX to an aldehyde or ketone gives α -halo alcohols, which are usually unstable, although exceptions are known, especially with perfluoro and perchloro species.⁴⁵⁶

F. Attack at Carbon by Organometallic Compounds⁴⁶⁰

16-24 The Addition of Grignard Reagents and Organolithium Reagents to Aldehydes and Ketones

O-Hydro-C-alkyl-addition

Organomagnesium compounds, commonly known as Grignard reagents (RMgX), are formed by the reaction of alkyl, vinyl, or aryl halides with magnesium metal, usually in ether solvents such as diethyl ether or THF (**12-38**), although the reaction can be done in water⁴⁶¹ under certain conditions. Halogen–magnesium exchange generates a Grignard reagent by reaction of aryl halides with reactive aliphatic Grignard reagents.⁴⁶² The addition of Grignard reagents to aldehydes and ketones⁴⁶³ is known as the *Grignard reaction*.⁴⁶⁴ The initial product is a magnesium alkoxide, requiring a hydrolysis step to generate the final alcohol product. Formaldehyde gives primary alcohols; other aldehydes give secondary alcohols; and ketones give tertiary alcohols. The reaction is of very broad scope. In many cases, the hydrolysis step is carried out with dilute HCl or H₂SO₄, but this cannot be done for tertiary alcohols in which at least one R group is alkyl because such alcohols are easily dehydrated under acidic conditions (**17-1**). In such cases (and often for other alcohols as well), an aqueous solution of ammonium chloride is used instead of a strong acid. Grignard reagents have been used in solid phase synthesis.⁴⁶⁵

⁴⁶⁵Fránzén, R.G. *Tetrahedron* **2000**, *56*, 685.

Alternative methods to generate the arylmagnesium compound are available, including the reaction of an aryl bromide with Bu_3MgLi in THF.⁴⁶⁶ Subsequent addition of an aldehyde leads to addition of the aryl group to form an alcohol. An interesting method to form an alkylmagnesium halide used dibutylmagnesium (Bu_2Mg) and a chiral diamine, and subsequent reaction with an aldehyde led to the alcohol derived from acyl addition of a butyl group with good enantioselectivity.⁴⁶⁷

Organolithium reagents (RLi), prepared from alkyl halides and lithium metal or by exchange of an alkyl halide with a reactive organolithium (**12-38**) react with aldehydes and ketones by acyl addition to give the alcohol,⁴⁶⁸ after hydrolysis. Organolithium reagents are more basic than the corresponding Grignard reagent, which leads to problems of deprotonation in some cases. Organolithium reagents are generally more nucleophilic, and can add to hindered ketones with relative ease when compared to the analogous Grignard reagent.⁴⁶⁹ These reagents tend to form aggregates, which influences the reactivity and selectivity of the addition reaction.⁴⁷⁰ Alkyl, vinyl⁴⁷¹ and aryl organolithium reagents can be prepared and undergo this reaction. Structural variations are also possible. A lithio-epoxide was formed by treating an epoxide with *sec*-butyllithium in the presence of sparteine,⁴⁷² or with *n*-butyllithium/TMEDA,⁴⁷³ and subsequent reaction with an aldehyde led to an epoxy alcohol. Treatment of an allenic silyl enol ether ($\text{R}_3\text{SiOC}=\text{C}=\text{C}$) with *tert*-butyllithium and then a ketone leads to acyl addition of a vinylolithium reagents to give a product with a conjugated ketone in which the $\text{C}=\text{C}$ is allylic to the alcohol, $\text{R}_3\text{SiC}(\text{=O})\text{C}(\text{=CH}_2)\text{—C}(\text{OH})\text{R}_2$.⁴⁷⁴ The dilithio compound $\text{LiC}\equiv\text{CCH}_2\text{Li}$ reacts with ketones via acyl addition, and an interesting workup with formaldehyde and then aqueous ammonium chloride gave the homopropargyl alcohol, $\text{R}_2\text{C}(\text{OH})\text{CH}_2\text{C}\equiv\text{CH}$.⁴⁷⁵ Aryl sulfonamides can be treated with 2 equivalents of *n*-butyllithium to give an ortho aryllithium which can then be added to an aldehyde to give the resulting diaryl carbinol.⁴⁷⁶ A very interesting variation of the fundamental acyl addition reaction of organolithium reagents treated an aldehyde with an acyl-lithio amide, $\text{LiC}(\text{=O})\text{N}(\text{Me})\text{CH}_2\text{Me}$, to give an α -hydroxy amide derivative.⁴⁷⁷

The reaction of aldehydes or ketones with alkyl and aryl Grignard reagents has also been done without preliminary formation of RMgX , by mixing RX the carbonyl compound and magnesium metal in an ether solvent. This approach

preceded Grignard's work, and is now known as the *Barbier reaction*.⁴⁷⁸ The organolithium analog of this process is also known.⁴⁷⁹ Yields were generally satisfactory. Carboxylic ester, nitrile, and imide groups in the R are not affected by the reaction conditions.⁴⁸⁰ Modern versions of the Barbier reaction employ other metals and/or reaction conditions, and will be discussed in **16-25**. A retro-Barbier reaction has been reported in which a cyclic tertiary alcohol was treated to an excess of bromine and potassium carbonate to give 6-bromo-2-hexanone from 1-methylcyclopentanol.⁴⁸¹ This section will focus on variations of the Barbier reaction that employ Mg or Li derivatives. The reaction of allyl iodide, benzaldehyde and Mg/I₂, for example, gave the acyl addition product 1-phenylbut-3-en-1-ol.⁴⁸²

The reaction of RMgX or RLi with α,β -unsaturated aldehydes or ketones can proceed via 1,4-addition as well as normal 1,2-addition (see **15-25**).⁴⁸³ In general, alkyllithium reagents give less 1,4-addition than the corresponding Grignard reagents.⁴⁸⁴ Quinones add Grignard reagents on one or both sides or give 1,4-addition. In a compound containing both an aldehyde and a ketone it is possible to add RMgX chemoselectively to the aldehyde without significantly disturbing the carbonyl of the ketone group⁴⁸⁵ (see also, p. 1306). In conjunction with BeCl₂, organolithium reagents add to conjugated ketones. In THF, 1,4- addition is observed, but in diethyl ether the 1,2-addition product is formed.⁴⁸⁶ Organocerium reagents, generated from cerium chloride (CeCl₃) and a Grignard reagent or an organolithium reagent) gives an organometallic reagent that adds chemoselectively.⁴⁸⁷ Grignard reagents with a catalytic amount of InCl₃ to give a mixture of 1,2- and 1,4-addition products with the 1,4-product predominating, but there was an increased 1,2-addition relative to the uncatalyzed reaction.⁴⁸⁸

As with the reduction of aldehydes and ketones (**19-36**), the addition of organometallic compounds to these substrates can be carried out enantioselectively and diastereoselectively.⁴⁸⁹ Chiral secondary alcohols have been obtained with high

enantioselectivity by addition of Grignard and organolithium compounds to aromatic aldehydes, in the presence of optically active amino alcohols as ligands.⁴⁹⁰

Diastereoselective addition⁴⁹¹ has been carried out with achiral reagents and chiral substrates,⁴⁹² similar to the reduction shown on p. 1802.⁴⁹³ Because the attacking atom in this case is carbon, not hydrogen, it is also possible to get diastereoselective addition with an achiral substrate and an optically active reagent.⁴⁹⁴ Use of suitable reactants creates, in the most general case, two new stereogenic centers, so the product can exist as two pairs of enantiomers:

Even if the organometallic compound is racemic, it still may be possible to get a diastereoselective reaction; that is, one pair of enantiomers is formed in greater amount than the other.⁴⁹⁵

In some cases, the Grignard reaction can be performed intramolecularly.⁴⁹⁶ For example, treatment of 5-bromo-2-pentanone with magnesium and a small amount

of mercuric chloride in THF produced 1-methyl-1-cyclobutanol in 60% yield.⁴⁹⁷ Other four- and five-membered ring compounds were also prepared by this procedure. Similar closing of five- and six-membered rings was achieved by treatment of a δ - or ϵ -halocarbonyl compound, not with a metal, but with a dianion derived from nickel tetraphenylporphine.⁴⁹⁸

The *gem*-disubstituted magnesium compounds formed from CH_2Br_2 or CH_2I_2 (**12-38**) react with aldehydes or ketones to give alkenes in moderate-to-good yields.⁴⁹⁹ Wittig type reacts also produce alkenes and are discussed in **16-44**. The reaction could not be extended to other *gem*-dihalides. Similar reactions with *gem*-dimetallic compounds prepared with metals other than magnesium have also produced alkenes.⁵⁰⁰ An interesting variation is the reaction of methyl-lithium and CH_2I_2 with an aliphatic aldehyde to give an epoxide,⁵⁰¹ but this reagent reacted with lactones to give a cyclic hemiketal with a pendant iodomethyl unit.⁵⁰² Alkylidene oxetanes react with lithium, and then with an aldehyde to give a conjugated ketone.⁵⁰³ The α,α -dimetallic derivatives of phenyl sulfones ($\text{PhSO}_2\text{CM}_2\text{R}$) ($\text{M} = \text{Li}$ or Mg) react with aldehydes or ketones $\text{R}'\text{COR}^2$ to give good yields of the α,β -unsaturated sulfones $\text{PhSO}_2\text{CR}=\text{CR}'\text{R}^2$,⁵⁰⁴ which can be reduced with aluminum amalgam (see **10-67**) or with $\text{LiAlH}_4\text{-CuCl}_2$ to give the alkenes $\text{CHR}=\text{CR}'\text{R}^2$.⁵⁰⁵ On the other hand, *gem*-dihalides treated with a carbonyl compound and Li or BuLi give epoxides⁵⁰⁶ (see also, **16-46**).

⁵⁰⁶Cainelli, G.; Tangari, N.; Umani-Ronchi, A. *Tetrahedron* **1972**, *28*, 3009, and references cited therein.

In other uses of *gem*-dihalo compounds, aldehydes and ketones add the CH_2I group [$\text{R}_2\text{CO} \rightarrow \text{R}_2\text{C}(\text{OH})\text{CH}_2\text{I}$] when treated with CH_2I_2 in the presence of SmI_2 ,⁵⁰⁷ and the CHX_2 group when treated with methylene halides and lithium dicyclohexylamide at low temperatures.⁵⁰⁸

A hydroxymethyl group can be added to an aldehyde or ketone with the masked reagent $\text{Me}_2((i\text{Pr})\text{O})\text{SiCH}_2\text{MgCl}$, which with R_2CO gives $\text{R}_2\text{C}(\text{OH})\text{CH}_2\text{Si}(\text{O}(i\text{Pr}))\text{Me}_2$, but with H_2O_2 give 1,2-diols $\text{R}_2\text{C}(\text{OH})\text{CH}_2\text{OH}$.⁵⁰⁹

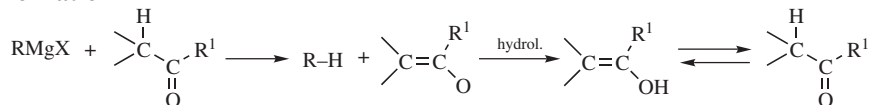

It is possible to add an acyl group to a ketone to give (after hydrolysis) an α -hydroxy ketone.⁵¹⁰ This can be done by adding RLi and CO to the ketone at -110°C :⁵¹¹

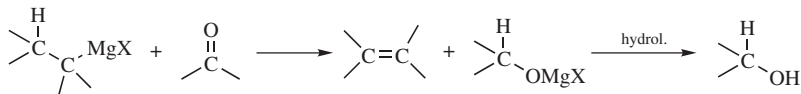

When the same reaction is carried out with carboxylic esters ($\text{R}'\text{COOR}^2$), α -diketones (RCOCOR') are obtained.⁵¹¹

Most aldehydes and ketones react with most Grignard reagents, but there are several potential side reactions⁵¹² that occur mostly with hindered ketones and with bulky Grignard reagents. The two most important of these are *enolization* and *reduction*. The former requires that the aldehyde or ketone have an α hydrogen, and the latter requires that the Grignard reagent have a β hydrogen:

Enolization

Reduction

⁵¹⁰For a review, see Seyferth, D.; Weinstein, R.M.; Wang, W.; Hui, R.C.; Archer, C.M. *Isr. J. Chem.* **1984**, 24, 167.

⁵¹¹Seyferth, D.; Weinstein, R.M.; Wang, W. *J. Org. Chem.* **1983**, 48, 1144; Seyferth, D.; Weinstein, R.M.; Wang, W.; Hui, R.C. *Tetrahedron Lett.* **1983**, 24, 4907.

⁵¹²Lajis, N. H.; Khan, M.N.; Hassan, H.A. *Tetrahedron* **1993**, 49, 3405.

Enolization is an acid–base reaction (**12-24**) in which a proton is transferred from the α carbon to the Grignard reagent. The carbonyl compound is converted to its enolate anion form, which, on hydrolysis, gives the original ketone or aldehyde. Enolization is important not only for hindered ketones but also for those that have a relatively high percentage of enol form (e.g., β -keto esters). In reduction, the carbonyl compound is reduced to an alcohol (**16-24**) by the Grignard reagent, which itself undergoes elimination to give an alkene. Two other side reactions are condensation (between enolate ion and excess ketone) and Wurtz-type coupling (**10-64**). Such highly hindered tertiary alcohols as triisopropylcarbinol, tri-*tert*-butylcarbinol, and diisopropylneopentylcarbinol cannot be prepared (or can be prepared only in extremely low yields) by the addition of Grignard reagents to ketones, because reduction and/or enolization become prominent.⁵¹³ However, these carbinols can be prepared by the use of alkyllithium reagents at -80°C ⁵¹⁴ because enolization and reduction are much less important.⁵¹⁵ Other methods of increasing the degree of addition at the expense of reduction include complexing the Grignard reagent with LiClO_4 or $\text{Bu}_4\text{N}^+ \text{Br}^-$,⁵¹⁶ or using benzene or toluene instead of ether as solvent.⁵¹⁷ Both reduction and enolization can be avoided by adding CeCl_3 to the Grignard reagent (see above).⁵¹⁸

Another way to avoid complications is to add $(\text{RO})_3\text{TiCl}$, TiCl_4 ,⁵¹⁹ $(\text{RO})_3\text{ZrCl}$, or $(\text{R}_2\text{N})_3\text{TiX}$ to the Grignard or lithium reagent. This produces organotitanium or organozirconium compounds that are much more selective than Grignard or organolithium reagents.⁵²⁰ An important advantage of these reagents is that they do not react with NO_2 or CN functions that may be present in the substrate, as Grignard and organolithium reagents do. The reaction of a β -keto amide with TiCl_4 , for example, gives a complex that allows selective reaction of the ketone unit with $\text{MeMgCl}-\text{CeCl}_3$ to give the corresponding alcohol.⁵²¹ Premixing an allylic Grignard reagent with ScCl_3 prior to reaction with the aldehyde gives direct acyl addition without allylic rearrangement as the major product, favoring the trans-alkene unit.⁵²²

There has been much controversy regarding the mechanism of addition of Grignard reagents to aldehydes and ketones.⁵²³ The reaction is difficult to study because of the variable nature of the species present in the Grignard solution (p. 260) and because the presence of small amounts of impurities in the magnesium seems to have a great effect on the kinetics of the reaction, making reproducible experiments difficult.⁵²⁴ There seem to be two basic mechanisms, depending on the reactants and the reaction conditions. In one of these, the R group is transferred to the carbonyl carbon with its electron pair. A detailed mechanism of this type has been proposed by Ashby and co-workers,⁵²⁵ based on the discovery that this reaction proceeds by two paths: one first order in MeMgBr and the other first order in Me₂Mg.⁵²⁶ According to this proposal, both MeMgBr and Me₂Mg add to the carbonyl carbon, though the exact nature of the step by which MeMgBr or Me₂Mg reacts with the substrate is not certain. One possibility is a four-centered cyclic transition state:⁵²⁷

The other type of mechanism is a single electron transfer (SET) process⁵²⁸ with a ketyl intermediate:⁵²⁹

This mechanism, which has been mostly studied with diaryl ketones, is more likely for aromatic and other conjugated aldehydes and ketones than it is for

⁵²⁹There is kinetic evidence that the solvent cage shown may not be necessary: Walling, C. *J. Am. Chem. Soc.* **1988**, 110, 6846.

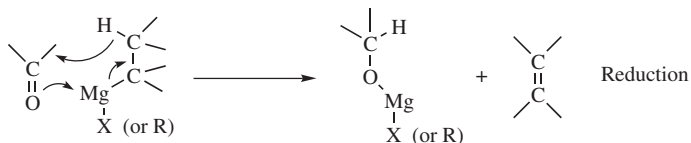

strictly aliphatic ones. Among the evidence⁵³⁰ for the SET mechanism are ESR spectra⁵³¹ and the fact that

side products are obtained (from dimerization of the ketyl).⁵³² In the case of addition of RMgX to benzil (PhCOCOPh), esr spectra of two different ketyl radicals were observed, both reported to be quite stable at room temperature.⁵³³ Note that a separate study failed to observe freely defusing radicals in the formation of Grignard reagents.⁵³⁴ Carbon isotope effect studies with $\text{Ph}^{14}\text{COPh}$ showed that the rate-determining step with most Grignard reagents is the carbon–carbon bond-forming step (marked A), though with allylmagnesium bromide it is the initial electron-transfer step.⁵³⁵ In the formation of Grignard reagents from bromocyclopropane, diffusing cyclopropyl radical intermediates were found.⁵³⁶ The concerted versus stepwise mechanism has been probed with chiral Grignard reagents.⁵³⁷

Mechanisms for the addition of organolithium reagents have been investigated much less.⁵³⁸ Addition of a cryptand that binds Li^+ inhibited the normal addition reaction, showing that the lithium is necessary for the reaction to take place.⁵³⁹

There is general agreement that the mechanism leading to reduction⁵⁴⁰ is usually as follows:

There is evidence that the mechanism leading to enolization is also cyclic, but involves prior coordination with magnesium:⁵⁴¹

Aromatic aldehydes and ketones can be alkylated and reduced in one reaction vessel by treatment with an alkyl- or aryllithium, followed by lithium and ammonia and then by ammonium chloride.⁵⁴²

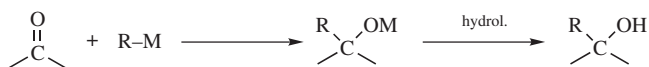

A similar reaction has been carried out with *N,N*-disubstituted amides: $\text{RCO}(\text{NR}_2) \rightarrow \text{RR}^2\text{CHNR}_2$.⁵⁴³

16-25 Addition of Other Organometallics to Aldehydes and Ketones

O-Hydro-*C*-alkyl-addition

A variety of organometallic reagents other than RMgX and RLi add to aldehydes and ketones. A simple example is formation of sodium, or potassium alkyne anions (e.g., $\text{RC}\equiv\text{CNa}$, **16-38**), which undergo acyl addition to ketones or aldehydes to give the propargylic alcohol. For the addition of acetylenic groups, sodium may be the metal used; while vinylic alanes (prepared as in **15-17**) are the reagents of choice for the addition of vinylic groups.⁵⁴⁴ A variation includes the use of tetraalkylammonium hydroxide to generate the alkyne anion,⁵⁴⁵ and terminal alkynes with CsOH react similarly.⁵⁴⁶ A solvent-free reaction was reported that mixed a ketone, a terminal alkyne and potassium *tert*-butoxide.⁵⁴⁷ The reagent $\text{Me}_3\text{Al}^-/\text{C}\equiv\text{CH}$

⁵⁴⁷Miyamoto, H.; Yasaka, S.; Tanaka, K. *Bull. Chem. Soc. Jpn.* **2001**, *74*, 185.

Na⁺ also adds to aldehydes to give the ethynyl alcohol.⁵⁴⁸ Dialkylzinc reagents have been used for the same purpose, and in the presence of a chiral titanium complex the propargylic alcohol was formed with good enantioselectivity.⁵⁴⁹ Zinc(II) chloride facilitates the addition of a terminal alkyne to an aldehyde to give a propargylic alcohol.⁵⁵⁰ Zinc(II) triflate can also be used for alkyne addition to aldehydes,⁵⁵¹ and in the presence of a chiral ligand leads to good enantioselectivity in the propargyl alcohol product.⁵⁵² Terminal alkynes add to aryl aldehydes in the presence of InBr₃ and NEt₃⁵⁵³ or SmI₂.⁵⁵⁴ 1-Iodoalkynes react with In metal and an aldehyde to give the propargylic alcohol.⁵⁵⁵ Potassium alkynyltrifluoroborates (p. 817) react with aldehydes and a secondary amine, in an ionic liquid, to give a propargylic amine.⁵⁵⁶

Propargylic acetate adds to aldehydes with good anti selectivity in the presence of Et₂Zn and a palladium catalyst.⁵⁵⁷ Propargylic bromide add to ketones in the presence of NaI/Dy,⁵⁵⁸ In,⁵⁵⁹ or Mn/Cr catalyst/TMSCl.⁵⁶⁰ Propargylic tin compounds react with aldehydes to give the alcohol, with good antiselectivity.⁵⁶¹

With other organometallic compounds, active metals, such as alkylzinc reagents,⁵⁶² are useful; and compounds such as alkylmercurys do not react. When the reagent is MeNbCl₄, ketones (R₂CO) are converted to R₂C(Cl)Me.⁵⁶³

Furthermore, organotitanium reagents can be made to add chemoselectively to aldehydes in the presence of ketones.⁵⁶⁴ Organomanganese compounds are also chemoselective in this way.⁵⁶⁵ Aryl halides that have a pendant ketone unit react with a palladium catalyst to give cyclization via acyl addition.⁵⁶⁶ Chiral amides react with aldehydes in the presence of TiCl_4 to give syn-selective addition products,⁵⁶⁷ and titanium-catalyzed enantioselective additions are known.⁵⁶⁸ An alkene-ketone, where the alkene is a vinyl bromide, reacted with $\text{CrCl}_2/\text{NiCl}_2$ to give a vinyl organometallic, which cyclized to generate a cyclic allylic alcohol with the double bond within the ring.⁵⁶⁹ Aryl halides react with a nickel complex under electrolytic conditions to add the aryl group to aldehydes.⁵⁷⁰ The C-3 position of an indole adds to aldehydes in the presence of a palladium catalyst.⁵⁷¹ The addition of trifluoromethyl to an aldehyde was accomplished photochemically using CF_3I and $(\text{Me}_2\text{N})_2\text{C}=\text{C}(\text{NMe}_2)_2$.⁵⁷² α -Iodo phosphonate esters react with aldehydes and SmI_2 to give a β -hydroxy phosphonate ester.⁵⁷³

Dialkylzinc compounds react with aldehydes to give the secondary alcohol, and R_3ZnLi reagents also add R to a carbonyl.⁵⁷⁴ Dimethylzinc and diethylzinc are probably the most common reagents. An intramolecular version is possible by reaction of an allene-aldehyde with dimethylzinc. Addition to the allene in the presence of a nickel catalyst⁵⁷⁵ or a CeCl_3 catalyst⁵⁷⁶ is followed by addition of the intermediate organometallic to the aldehyde to give the cyclic product. Aryl halides react with Zn-Ni complexes to give acyl addition of the aryl group to an aldehyde.⁵⁷⁷ The reaction of an allylic halide and Zn ⁵⁷⁸ or Zn/TMSCl ⁵⁷⁹ leads to acyl addition of aldehydes.

Lithium dimethylcopper (Me_2CuLi) reacts with aldehydes⁵⁸⁰ and with certain ketones⁵⁸¹ to give the expected alcohols. The $\text{RCu}(\text{CN})\text{ZnI}$ reagents also react with aldehydes, in the presence of BF_3 –etherate, to give secondary alcohols. Vinyl-tellurium compounds react with $\text{BF}_3 \cdot \text{OEt}_2$ and cyano cuprates $[\text{R}(2\text{-thienyl})\text{CuCN-Li}_2]$ to give a reagent that adds 1,2- to the carbonyl of a conjugated ketone.⁵⁸² Vinyl tellurium compounds also react with *n*-butyllithium to give a reagent that adds to nonconjugated ketones.⁵⁸³

Many methods have been reported for the addition of allylic groups,⁵⁸⁴ including enantioselective reactions.⁵⁸⁵ One of the most common methods is the Barbier reaction, employing metals and metal compounds other than Mg or Li, although the method is not limited to allylic compounds. Allyl indium compounds⁵⁸⁶ add to aldehydes or ketones in various solvents.⁵⁸⁷ Indium metal is used for the acyl addition of allylic halides with a variety of aldehydes and ketones, including aliphatic aldehydes,⁵⁸⁸ aryl aldehydes⁵⁸⁹ and α -keto esters.⁵⁹⁰ Indium reacts with allylic bromides and ketones in water⁵⁹¹ and in aqueous media. Elimination of the homoallylic alcohol to a conjugated diene can accompany the addition in some cases.⁵⁹² The reaction of a propargyl halide, In, and an aldehyde in aq. THF leads to an allenic alcohol.⁵⁹³ The reaction of benzaldehyde with a propargylic bromide, indium metal and water give the alcohol.⁵⁹⁴ Allyl bromide reacts with Mn/TMSCl and an In catalyst in water to give the homoallylic

alcohols from aldehydes.⁵⁹⁵ When allyl iodide is mixed with In and TMSCl, reaction with a conjugated ketone proceed by 1,4-addition, but in the presence of 10% CuI, the major product is that of 1,2-addition.⁵⁹⁶ The reaction with indium is compatible with the presence of a variety of other functional groups in the molecule, including phosphonate,⁵⁹⁷ propargylic sulfides.⁵⁹⁸ Ethyl α -bromoacetate reacts with aldehydes using In with ultrasound.⁵⁹⁹ Vinyl epoxides can be added to aldehydes using InI and a palladium catalyst,⁶⁰⁰ and vinyl acetates react with indium metal to give a reactive intermediate that adds to the carbonyl of aldehydes.⁶⁰¹ A tandem reaction has been reported in which a bis(indium) reagent, $\text{Br}_2\text{InC}(\text{=CH}_2)\text{-C}(\text{=CH}_2)\text{InBr}_2$, reacts with 2 equivalents of an aldehyde in the presence of ZnF_2 to give a 3-hexyne-1,6-diol derivative.⁶⁰² Alkyl halides react with Zn/Cu and an InCl catalyst, in the presence of 0.07 M $\text{Na}_2\text{Cr}_2\text{O}_7$ to give an intermediate that adds to aldehydes.⁶⁰³ Analogous to aldehydes, 1,1-diacetates react with In and allyl bromide in aq. THF to give a homoallylic acetate,⁶⁰⁴ as do dimethyl ketals.⁶⁰⁵ Allylic alcohols react with InI and a nickel catalyst to give acyl addition of an allylic group to an aldehyde, giving the homoallylic alcohol.⁶⁰⁶

Another important metal for Barbier-type reaction is samarium. Allyl bromide reacts with a ketone and Sm to give the homoallylic alcohol.⁶⁰⁷ Samarium compounds, such as SmI_2 ,⁶⁰⁸ can also be used with allylic halides.

Allyltin compounds readily add to aldehydes and ketones.⁶⁰⁹ Allylic bromides react with tin to generate the organometallic *in situ*, which then adds to aldehydes.⁶¹⁰ Allylic chlorides react with aldehydes in the presence of ditin compounds such as $\text{Me}_3\text{Sn-SnMe}_3$ and a palladium catalyst.⁶¹¹ Allyltrialkyltin compounds⁶¹²

give the dienyl alcohol.⁶³⁶ Allenyl tin compounds ($\text{CH}_2=\text{C}=\text{CHSnBu}_3$) also react with aldehydes in the presence of $\text{BF}_3\cdot\text{OEt}_2$ to give a 2-dienyl alcohol.⁶³⁷ The tin compound can be prepared *in situ* using an α -iodo ketone with an aldehyde and $\text{Bu}_2\text{SnI}_2\text{--LiI}$.⁶³⁸ A similar addition occurs with $(\text{allyl})_2\text{SnBr}_2$ in water.⁶³⁹ Asymmetric induction has been reported.⁶⁴⁰ The use of a chiral rhodium⁶⁴¹ or titanium⁶⁴² catalyst leads to enantioselective addition of allyltributyltin to aldehydes. Allyltributyltin reacts with aldehydes in the presence of SiCl_4 and a chiral phosphoramidate to give the homoallylic alcohol with moderate enantioselectivity.⁶⁴³ It is noted that tetraallyl germanium adds to aldehydes in a similar manner in the presence of a $\text{Sc}(\text{OTf})_3$ catalyst.⁶⁴⁴

A variety of other allylic metal compounds add to aldehydes or ketones.⁶⁴⁵ A variety of alkyl and allylic halides add to aldehydes or ketones in the presence of metals or metal compounds; the metal or compounds based on Ti,⁶⁴⁶ Mn,⁶⁴⁷ Fe,⁶⁴⁸ Ga,⁶⁴⁹

Ge,⁶⁵⁰ Zr,⁶⁵¹ Nb,⁶⁵² Cd,⁶⁵³ Sn,⁶⁵⁴ Sb,⁶⁵⁵ Te,⁶⁵⁶ Ba,⁶⁵⁷ Ce,⁶⁵⁸ Nd,⁶⁵⁹ Hg,⁶⁶⁰ Bi,⁶⁶¹ and Pb.⁶⁶² In addition, BiCl₃/NaBH₄,⁶⁶³ Mg–BiCl₃,⁶⁶⁴ and CrCl₂/NiCl₂,⁶⁶⁵ have been used. Allylic alcohols have been converted to organometallic reagents with diethyl zinc and a palladium catalyst⁶⁶⁶ or a ruthenium catalyst⁶⁶⁷ leading to the homoallylic alcohol upon reaction with an aldehyde. A chiral Cr/Mn complex has been used with allylic bromides in conjunction with trimethylsilyl chloride.⁶⁶⁸ Reagents of the type R–Yb have been prepared from RMgX.⁶⁶⁹ Vinyl bromides react with NiBr₂/CrCl₃/TMSCl to give a reagent that adds to aldehydes to give the allylic alcohol.⁶⁷⁰ Vinyl complexes generated from alkynes and SmI₂ add intramolecularly, and eight-membered rings have been formed in this way.⁶⁷¹ Allylic alcohols add to aldehydes in some cases, using SnCl₂ and a palladium catalyst.⁶⁷² Glyoxal reacted with 2 equivalents of allyl bromide and SnCl₂ with KI in water, to give the bis-homoallylic alcohol oct-1,7-diene-4,5-diol.⁶⁷³ The alkyl group of trialkyl aluminum compounds such as AlEt₃ add to aldehydes, enantioselectively in the presence of chiral transition-metal complexes.⁶⁷⁴ Certain functional groups (COOEt, CONMe₂, CN) can be present in the R group when

organotin reagents RSnEt_3 are added to aldehydes.⁶⁷⁵ Trimethylaluminum⁶⁷⁶ and dimethyltitanium dichloride⁶⁷⁷ exhaustively methylate ketones to give *gem*-dimethyl compounds⁶⁷⁸ (see also **10-63**):

The titanium reagent also dimethylates aromatic aldehydes.⁶⁷⁹ Triethylaluminum reacts with aldehydes, however, to give the mono-ethyl alcohol, and in the presence of a chiral additive the reaction proceeds with good asymmetric induction.⁶⁸⁰ A complex of $\text{Me}_3\text{Ti}\cdot\text{MeLi}$ has been shown to be selective for 1,2-addition with conjugated ketones, in the presence of nonconjugated ketones.⁶⁸¹ In other variations, the organometallic reagent is generated *in situ*. 1,4-Dimethoxybenzene reacts with ethyl glyoxylate ($\text{EtO}_2\text{C}-\text{CHO}$) in the presence of 5% $\text{Yb}(\text{OTf})_3$, to give the alcohol formed by addition of the aryl group to the aldehyde unit.⁶⁸²

High ee values have also been obtained with organometallics,⁶⁸³ including organotitanium compounds (methyl, aryl, allylic) in which an optically active ligand is coordinated to the titanium,⁶⁸⁴ allylic boron compounds, and organozinc compounds. As for the organozinc reagents, very high enantioselection was obtained from R_2Zn reagents ($\text{R} = \text{alkyl}$)⁶⁸⁵ and aromatic⁶⁸⁶ aldehydes by the use of a small

amount of various catalysts.⁶⁸⁷ The enantioselectivity is influenced by additives, such as LiCl.⁶⁸⁸ Silica-immobilized chiral ligands⁶⁸⁹ can be used in conjunction with dialkylzinc reagents, and polymer-supported ligands have been used.⁶⁹⁰ Chiral dendritic titanium catalysts have been used to give moderate enantioselectivity.⁶⁹¹

Enantioselective reaction of a carbonyl with a dialkylzinc is possible when other functional groups are present in the molecule. Examples include keto esters.⁶⁹² An enzyme-mediated addition of dialkylzinc reagents to aldehydes has also been reported.⁶⁹³ When benzaldehyde was treated with Et₂Zn in the presence of the optically active catalyst 1-piperidino-3,3-dimethyl-2-butanol, a surprising result was obtained. Although the catalyst had only 10.7% excess of one enantiomer, the

product PhCH(OH)Me had an ee of 82%.⁶⁹⁴ When the catalyst ee was increased to 20.5%, the product ee rose to 88%. The question is, how could a catalyst produce a product with an ee much higher than itself? One possible explanation⁶⁹⁵ is that (*R*) and (*S*) molecules of the catalyst form a complex with each other, and that only the uncomplexed molecules are actually involved in the reaction. Since initially the number of (*R*) and (*S*) molecules was not the same, the (*R/S*) ratio of the uncomplexed molecules must be considerably higher (or lower) than that of the initial mixture.

Although organoboranes do not generally add to aldehydes and ketones,⁶⁹⁶ allylic boranes are exceptions.⁶⁹⁷ When they add, an allylic rearrangement always takes place. Allylic rearrangements take place with the other reagents as well. The use of a chiral catalyst leads to asymmetric induction⁶⁹⁸ and chiral allylic boranes have been prepared.⁶⁹⁹ It is noted that chloroboranes (R_2BCl) react with aldehydes via acyl addition of the alkyl group, giving the corresponding alcohol after treatment with water.⁷⁰⁰ A variation is the reaction of a diketone, where one carbonyl is conjugated. Treatment with catecholborane gives addition to the conjugated ketone, and subsequent cyclization of the resulting organometallic at the nonconjugated ketone gives a cyclic alcohol with a pendant ketone unit, after treatment with methanol.⁷⁰¹ In the presence of ruthenium complexes, $RB(OH)_2$ and arylboronic acids $ArB(OH)_2$ (p. 815) add to aldehydes to give the corresponding alcohol.⁷⁰² Polymer-bound aryl borates add an aryl group to aldehydes in the presence of a rhodium catalyst.⁷⁰³ An intramolecular version of the phenylboronic acid-induced reaction is known, where a molecule with ketone and conjugated ketone units is converted to a cyclic alcohol using a chiral rhodium catalyst.⁷⁰⁴ Allylic boronates add to aldehydes.⁷⁰⁵

⁷⁰⁵For a review of the scandium-catalyzed enantioselective addition, see Gravel, M.; Lachance, H.; Lu, X.; Hall, D.G. *Synthesis* **2004**, 1290.

A number of optically active allylic boron compounds have been used, including ⁷⁰⁶ B-allylbis(2-isocaranyl)borane (**30**), ⁷⁰⁷ (*E*)- and (*Z*)-crotyl-(*R,R*)-2,5-dimethylborolanes (**31**), ⁷⁰⁸ and the borneol

derivative **32**,⁷⁰⁹ all of which add an allyl group to aldehydes, with good enantioselectivity. Where the substrate possesses an aryl group or a triple bond, enantioselectivity is enhanced by using a metal carbonyl complex of the substrate.⁷¹⁰

Alkenes and alkynes add to aldehydes or ketones by conversion to a reactive organometallic. A radical-type addition is possible using alkenes with BEt_3 . Benzaldehyde reacted with isoprene in the presence of BEt_3 and $\text{Ni}(\text{acac})_2$ to give an anti-Markovnikov-type addition to the carbonyl, $\text{C}=\text{C}-\text{C}(\text{Me})=\text{C} + \text{PhCHO} \rightarrow \text{C}=\text{CCHMeCH}_2\text{CH}(\text{OH})\text{Ph}$.⁷¹¹ Alkynes add to aldehydes elsewhere in the same molecule in the presence of BEt_3 and a nickel catalyst to give a cyclic allylic alcohol.⁷¹² Alkene aldehydes react similarly using Me_3SiOTf .⁷¹³ In a similar manner, dienes add to aldehydes in the presence of a nickel catalyst.⁷¹⁴ Propargylic halides add to aldehydes to give an allenic alcohol using $\beta\text{-SnO}[\text{Rd}(\text{cod})\text{Cl}]_2$.⁷¹⁵ Allylic acetates react with ketones to give the homoallylic alcohol under electrochemical conditions that include bipyridyl, tetrabutylammonium tetrafluoroborate and FeBr_2 .⁷¹⁶ Terminal alkynes react with zirconium complexes and Me_2Zn to give an allylic tertiary alcohol.⁷¹⁷ Internal alkynes also give allylic alcohols in the presence of BEt_3 and a nickel catalysts.⁷¹⁸ Reaction of an aldehyde containing a conjugated diene unit with diethylzinc and a nickel catalyst leads to cyclic

alcohols having a pendant allylic unit.⁷¹⁹ A similar reaction was reported using a copper catalyst.⁷²⁰ Vinyl iodides also react with Cp_2ZrCl_2 to give a vinylzirconium complex that reacts with aldehydes.⁷²¹ The intramolecular addition of an alkene to an aldehyde leads to a saturated cyclic alcohol using PhSiH_3 and a cobalt catalyst.⁷²² Intramolecular addition of a conjugated ester (via the β -carbon) to an aldehyde generates a cyclic ketone.⁷²³ This type of coupling has been called the *Stetter reaction*,⁷²⁴ which actually involves the addition of aldehydes to activated double bonds (**15-34**), mediated by a catalytic amount of thiazolium salt in the presence of a weak base. The intramolecular addition of the allene moiety to an aldehyde is catalyzed by a palladium complex in the presence of $\text{Me}_3\text{SiSn-Bu}_3$.⁷²⁵ A highly enantio- and diastereoselective intramolecular Stetter reaction has been developed.⁷²⁶ Alkynyl aldehydes react with silanes such as Et_3SiH and a nickel catalyst to give a cyclic compound having a silyl ether and an exocyclic vinylidene unit.⁷²⁷ Alkene-aldehydes give cyclic alcohols via intramolecular addition of the $\text{C}=\text{C}$ unit to the carbonyl under electrolytic conditions using a phase-transfer catalyst.⁷²⁸ A similar cyclization was reported using SnCl_4 .⁷²⁹ Vinylidene cycloalkanes react with aldehydes in the presence of a palladium catalyst to give a homoallylic alcohol where addition occurs at the carbon exocyclic to the ring.⁷³⁰ Alkenes having an allylic hydrogen react with α -keto aldehydes, with a cobalt catalyst, to give α -hydroxy ketones where the alcohol is homoallylic relative to the $\text{C}=\text{C}$ unit.⁷³¹ Allenes react with benzaldehyde using HCl-SnCl_2 with a palladium catalyst.⁷³² Silyl allenenes react with aldehydes in the presence of a chiral scandium catalyst to give homopropargylic alcohols with good enantioselectivity.⁷³³ Intramolecular addition of an allene to aldehyde via addition of phenyl when treated with PhI and a palladium catalyst.⁷³⁴ Allenes add to ketones

to give homoallylic alcohols in the presence of SmI_2 and HMPA.⁷³⁵ Allenes add to carbonyl groups in the presence of 2.2 equivalents of SmI_2 and an excess of HMPA.⁷³⁶ Alkenes have an allylic methyl group add to formaldehyde, in the presence of $\text{BF}_3 \cdot \text{OEt}_2$, to give a homoallylic alcohol.⁷³⁷ Conjugated dienes react with aldehyde via acyl addition of a terminal carbon of the diene, in the presence of $\text{Ni}(\text{acac})_2$ and Et_2Zn .⁷³⁸ Aldehydes having an allylic acetate unit elsewhere in the molecule undergo cyclization in CO and a ruthenium catalyst to give a cyclic alcohol with a pendant vinyl group.⁷³⁹

Allylic trifluoroborates (p. 817) react with aldehydes to give the homoallylic alcohol. Pivaldehyde reacts with potassium 2-butenyltrifluoroborate and a catalytic amount of tetrabutylammonium iodide to give 2,2,4-trimethylhex-5-en-3-ol.⁷⁴⁰ Aliphatic aldehydes react with this reagent, in the presence of $\text{BF}_3 \cdot \text{OEt}_2$, to give the homoallylic alcohol with allylic rearrangement and a preference for the syn diastereomer,⁷⁴¹ and aryl aldehydes react as well.⁷⁴²

16-26 Addition of Trialkylallylsilanes to Aldehydes and Ketones

O-Hydro-C-alkyl-addition

Allylic trialkyl, trialkoxy, and trihalosilanes add to aldehydes to give the homoallylic alcohols in the presence of a Lewis acid⁷⁴³ (including TaCl_5 ⁷⁴⁴ and YbCl_3 ⁷⁴⁵), Me_3SiOTf ,⁷⁴⁶ fluoride ion,⁷⁴⁷ proazaphosphatranes,⁷⁴⁸ or a catalytic amount of iodine.⁷⁴⁹ The mechanism of this reaction has been examined.⁷⁵⁰ A ruthenium catalyst has also been used in conjunction with an arylsilane and an aldehyde.⁷⁵¹

The reaction of an allene aldehyde with Et_3SiH , CO and a rhodium catalyst leads to addition to the alkene followed by intramolecular addition to the aldehyde to give the cyclic alcohol.⁷⁵² Allyl(trimethoxy)silane adds an allyl group to aldehydes using a CdF_2 ⁷⁵³ catalyst or a chiral AgF complex.⁷⁵⁴ Allyltrichlorosilanes have also been used in addition reactions with aldehydes.⁷⁵⁵ Hünig's base ($i\text{Pr}_2\text{NET}$) and a sulfoxide have also been used to facilitate the addition of an allyl group to an aldehyde from allyltrichlorosilane.⁷⁵⁶

Allyltrichlorosilane reacts with benzaldehyde in the presence of Bu_4NF to give 1-phenylbut-3-en-1-ol,⁷⁵⁷ and with a chiral additive the reaction proceeds with good enantioselectivity. When chiral titanium complexes are used in the reaction, allylic alcohols are produced with good asymmetric induction.⁷⁵⁸ Other chiral additives have been used,⁷⁵⁹ as well as chiral catalysts,⁷⁶⁰ and chiral complexes of allyl silanes.⁷⁶¹ Chiral allylic silyl derivatives add to aldehydes to give the chiral homoallylic alcohol.⁷⁶²

Allylic silanes react with *gem*-diacetates in the presence of InCl_3 to give a homoallylic acetate⁷⁶³ or with dimethyl acetals and TMSOTf in an ionic liquid to give the homoallylic methyl ether.⁷⁶⁴ Allylic alcohols can be treated with TMS-Cl and NaI, and then Bi to give an organometallic reagent that adds to aldehydes.⁷⁶⁵

In the presence of a base,⁷⁶⁷ such as 1,4-diazabicyclo[2.2.2]octane (DABCO) or trialkylphosphines, conjugated carbonyl compounds (ketones, esters,⁷⁶⁸ thioesters,⁷⁶⁹ and amides⁷⁷⁰) add to aldehydes via the α -carbon to give α -alkenyl- β -hydroxy esters or amides. This sequence is called the *Baylis–Hillman reaction*,⁷⁷¹ and a simple example is the formation of **33**.⁷⁷² It was observed that methyl vinyl ketone gave other products in the Baylis–Hillman reaction, whereas conjugated esters did not.⁷⁷³ Methods that are catalytic in base have been developed for the Baylis–Hillman reaction.⁷⁷⁴ Both microwave irradiation⁷⁷⁵ and ultrasound⁷⁷⁶ have been used to induce the reaction. Under certain conditions, rate enhancements have been observed.⁷⁷⁷ Rate acceleration occurs with bis-aryl(thio)ureas in a DABCO-promoted reaction.⁷⁷⁸ The reaction has been done in ionic liquids⁷⁷⁹ and polyethylene glycol (PEG)⁷⁸⁰ or sulpholane.⁷⁸¹ Alkynyl carbonyl compounds can be used as partners in the Baylis–Hillman reaction.⁷⁸² Transition metal compounds can facilitate the Baylis–Hillman reaction, and $\text{BF}_3 \cdot \text{OEt}_2$ has been used.⁷⁸³ With the boron trifluoride

induced reaction between an aldehyde and a conjugated ketone, a saturated β -hydroxy ketone was formed with good antiselectivity.⁷⁸⁴ The coupling of aldehydes with conjugated ketones was accomplished with TiCl_4 ,⁷⁸⁵ dialkylaluminum halides,⁷⁸⁶ and with (polymethyl)hydrosiloxane and a copper catalyst.⁷⁸⁷ Conjugated esters were coupled to aldehydes with DABCO and a lanthanum catalyst.⁷⁸⁸ Aldehydes were coupled to conjugated nitriles with TiCl_4 .⁷⁸⁹ The reaction of a conjugated ester, an aldehyde and LiClO_4 , with 15% DABCO gave the allylic alcohol product.⁷⁹⁰ *N*-Tosyl imines can be used in place of aldehydes, and the reaction of the imine, a conjugated ester and DABCO gave the allylic *N*-tosylimine.⁷⁹¹ Aldehydes are coupled to conjugated esters with a chiral quinuclidine catalyst and a titanium catalyst, and in the presence of tosylamine, the final product was the allylic *N*-tosylamine formed with modest enantioselectivity.⁷⁹²

An intramolecular version of the Baylis–Hillman reaction generated cyclopentene derivatives from alkyne-aldehydes and a rhodium catalyst.⁷⁹³ Another intramolecular reaction gave cyclopentenols via cyclization of an aldehyde-conjugated thioester upon treatment with DBU and DMAP.⁷⁹⁴ Cyclization of a conjugated ester using DABCO, where the “alcohol” group contained an aldehyde unit (an α -hydroxy aldehyde derivative) gave a lactone with an hydroxy unit at C3 relative to the carbonyl and an α -vinylidene.⁷⁹⁵ A “double Baylis–Hillman” reaction has also been reported using *N*-tosylimines and conjugated ketones.⁷⁹⁶

Using a chiral auxiliary via an amide⁷⁹⁷ or ester⁷⁹⁸ leads to asymmetric induction.⁷⁹⁹ Aryl aldehydes and conjugated ketones were condensed using proline, leading to modest enantioselectivity.⁸⁰⁰ Chiral biaryl catalysts have been used with trialkylphosphines, giving good enantioselectivity.⁸⁰¹ Chiral quinuclidine catalysts lead to

asymmetric induction.⁸⁰² A combination of a chiral sulfinamide, an In catalyst and 3-hydroxyquinuclidine led to the allylic amine derivative with modest enantioselectivity.⁸⁰³ Sugars have been used as ester auxiliaries, and in reaction with aryl aldehydes and 20% DABCO gave the allylic alcohol with modest enantioselectivity.⁸⁰⁴

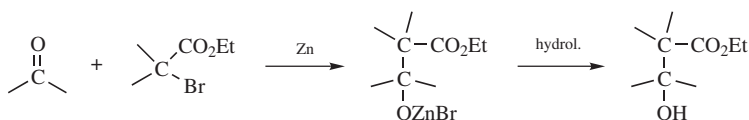

The reaction can be modified to give additional products, as with the reaction of *o*-hydroxybenzaldehyde and methyl vinyl ketone with DABCO, where the initial Baylis–Hillman product cyclized via conjugate addition of the phenolic oxygen to the conjugated ketone (**15-31**).⁸⁰⁵ Aldehydes and conjugated esters can be coupled with a sulfonamide to give an allylic amine.⁸⁰⁶

A variant of this reaction couples halides with alkenes. α -Bromomethyl esters react with conjugated ketones and DABCO to give a coupling product, **34**.⁸⁰⁷ A similar DBU-induced reaction was reported using α -bromomethyl esters and conjugated nitro compounds.⁸⁰⁸

16-28 The Reformatsky Reaction

O-Hydro-*C*- α -ethoxycarbonylalkyl-addition

The *Reformatsky reaction*⁸⁰⁹ is very similar to **16-24**. An aldehyde or ketone is treated with zinc and a halide; the halide is usually an α -halo ester or a vinylog of an α -halo ester (e.g., RCHBrCH=CHCOOEt), though α -halo nitriles,⁸¹⁰ α -halo ketones,⁸¹¹ and α -halo *N,N*-disubstituted amides have also been used. Especially

high reactivity can be achieved with activated zinc,⁸¹² with zinc/silver-graphite,⁸¹³ and with zinc and ultrasound.⁸¹⁴ The reaction is catalytic in zinc in the presence of iodine and ultrasound.⁸¹⁵ Metals other than zinc can be used, including In,⁸¹⁶ Mn,⁸¹⁷ low valent Ti,⁸¹⁸ and metal compounds, such as TiI₄,⁸¹⁹ TiCl₂,⁸²⁰ Cp₂TiCl₂,⁸²¹ (Bu₃Sn)₂/Bu₂SnCl₂,⁸²² SmI₂,⁸²³ and Sc(OTf)₃/PPh₃.⁸²⁴ A combination of Zn and an α -bromo ester can be used in conjunction with BF₃·OEt₂, followed by reaction with dibenzoyl peroxide.⁸²⁵ The aldehyde or ketone can be aliphatic, aromatic, or heterocyclic or contain various functional groups. Solvents used are generally ethers, including Et₂O, THF, and 1,4-dioxane, although the reaction can be done in water⁸²⁶ using dibenzoyl peroxide and MgClO₄.

Dialkylzinc compounds are an alternative source of zinc in the Reformatsky reaction. When an α -bromo ester, an aldehyde, and diethylzinc were reacted in THF with a rhodium catalyst, the β -hydroxy ester was formed.⁸²⁷

The use of additives, such as germanium, can lead to highly diastereoselective reactions.⁸²⁸ Using chiral auxiliaries⁸²⁹ or chiral additives,⁸³⁰ good enantioselectivity⁸³¹ can be achieved.

Formally, the reaction can be regarded as if it were analogous to the Grignard reaction (16-24), with

(35) as an intermediate analogous to RMgX .⁸³² There is an intermediate derived from zinc and the ester, the structure of which has been shown to be **36**, by X-ray crystallography of the solid intermediate prepared from $t\text{-BuOCOCH}_2\text{Br}$ and Zn .⁸³³ As can be seen, it has some of the characteristics of **35**.

After hydrolysis, the alcohol is the usual product, but sometimes (especially with aryl aldehydes) elimination follows directly and the product is an alkene. By the use of Bu_3P along with Zn , the alkene can be made the main product,⁸³⁴ making this an alternative to the Wittig reaction (**16-44**). The alkene is also the product when $\text{K}_2\text{CO}_3/\text{NaHCO}_3$ is used with 2% PEG-telluride.⁸³⁵ Since Grignard reagents cannot be formed from α -halo esters, the method is quite useful, though there are competing reactions and yields are sometimes low. A similar reaction (called the *Blaise reaction*) has been carried out on nitriles:⁸³⁶

Carboxylic esters have also been used as substrates, but then, as might be expected (p. 1252), the result is substitution and not addition:

The product in this case is the same as with the corresponding nitrile, though the pathways are different. The reaction is compatible with amine substituents, and α -(*N,N*-dibenzyl)amino aldehydes have been used to prepare β -hydroxy- γ -(*N,N*-dibenzylamino) esters with good anti-selectivity.⁸³⁷

16-29 The Conversion of Carboxylic Acid Salts to Ketones with Organometallic Compounds

Alkyl-de-oxido-substitution

Good yields of ketones can often be obtained by treatment of the lithium salt of a carboxylic acid with an alkyllithium reagent, followed by hydrolysis.⁸³⁸ The R' group may be aryl or primary, secondary, or tertiary alkyl and R may be alkyl or aryl. The compounds MeLi and PhLi have been employed most often. Tertiary alcohols are side products. Lithium acetate can be used, but generally gives low yields.

A variation of this transformation reacts the acid with lithium naphthalenide in the presence of 1-chlorobutane. The product is the ketone.⁸³⁹ A related reaction treats the lithium carboxylate with lithium metal and the alkyl halide, with sonication, to give the ketone.⁸⁴⁰ Phenylboronic acid (p. 815) reacts with aryl carboxylic acids in the presence of a palladium catalyst and disuccinoyl carbonate to give a diaryl ketone.⁸⁴¹

OS **V**, 775.

16-30 The Addition of Organometallic Compounds to CO₂ and CS₂

C-Alkyl-O-halomagnesio-addition

Grignard reagents add to one C=O bond of CO₂ exactly as they do to an aldehyde or a ketone.⁸⁴² Here, of course, the product is the salt of a carboxylic acid. The reaction is usually performed by adding the Grignard reagent to dry ice. Many carboxylic acids have been prepared in this manner, and this constitutes an important way of increasing a carbon chain by one unit. Since labeled CO₂ is commercially

available, this is a good method for the preparation of carboxylic acids labeled in the carboxyl group. Other organometallic compounds have also been used (RLi,⁸⁴³ RNa, RCaX, RBa,⁸⁴⁴ etc.), but much less often. The formation of the salt of a carboxylic acid after the addition of CO₂ to a reaction mixture is regarded as a positive test for the presence of a carbanion or of a reactive organometallic intermediate in that reaction mixture (see also, **16-42**).

When chiral additives, such as (–)-sparteine, have added to the initial reaction with the organolithium reagent, quenching with CO₂ produces carboxylic acids with good asymmetric induction.⁸⁴⁵

In a closely related reaction, Grignard reagents add to CS₂ to give salts of dithiocarboxylic acids.⁸⁴⁶ These salts can be trapped with amines to form thioamides.⁸⁴⁷ Two other reactions are worthy of note. (1) Lithium dialkylcopper reagents react with dithiocarboxylic esters to give tertiary thiols⁸⁴⁸ (2) Thiono lactones can be converted to cyclic ethers,⁸⁴⁹ for example:

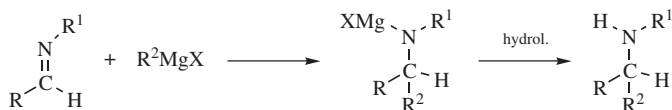

This is a valuable procedure because medium and large ring ethers are not easily made, while the corresponding thiono lactones can be prepared from the readily available lactones (see, e.g., **16-63**) by reaction **16-11**.

A terminal alkyne can be converted to the anion under electrolytic conditions, in the presence of CO₂, to give propargylic acids, R–C≡C–COOH.⁸⁵⁰

Aldimines can be converted to secondary amines by treatment with Grignard reagents.⁸⁵¹ Ketimines generally give reduction instead of addition. However, organolithium compounds give the normal addition product with both aldimines and ketimines.⁸⁵² For the addition of an organometallic compound to an imine to give a primary amine, R' in RCH=NR' would have to be H, and such compounds are seldom stable. However, the conversion has been done, for R = aryl, by the use of the masked reagents (ArCH=N)₂SO₂ [prepared from an aldehyde RCHO and sulfamide (NH₂)₂SO₂]. Addition of R²MgX or R²Li to these compounds gives ArCHR²NH₂ after hydrolysis.⁸⁵³ An intramolecular version of the addition or organolithium reagents is known, and treatment of the *N*-(3-chloropropyl)aldimine of benzaldehyde with lithium and DTBB, followed by hydrolysis with water, gave 2-phenylpyrrolidine.⁸⁵⁴ Grignard reagents add to imines in the presence of various transition metal catalysts, including Sc(OTf)₃⁸⁵⁵ or Cp₂ZrCl₂.⁸⁵⁶ When chiral additives are used in conjunction with the organolithium reagent, chiral amines are produced⁸⁵⁷ with good asymmetric induction.⁸⁵⁸ Chiral auxiliaries have been used in addition reactions to imines,⁸⁵⁹ and to oxime derivatives.⁸⁶⁰ Chiral catalysts lead to enantioselective addition of alkynes to imines to give a homopropargylic amine.⁸⁶¹

Zinc metal reacts with allylic bromides to form an allylic zinc complex, which reacts with imines to give the homoallylic amine.⁸⁶² This reaction is catalyzed by TMSCl.⁸⁶³ Allylzinc bromide adds to imines.⁸⁶⁴ Dialkylzinc reagents add to imines to give the amine, and in the presence of a chiral ligand the reaction proceeds with

good enantioselectivity.⁸⁶⁵ Dialkylzinc reagents add to *N*-tosyl imines using a copper catalyst, and with a chiral ligand leads to good enantioselectivity.⁸⁶⁶ α -Bromo esters are converted to an organometallic reagent with Zn/Cu, and addition to *N*-arylimines gives *N*-aryl β -amino esters.⁸⁶⁷ The reaction of imines, such as $\text{ArN}=\text{CHCO}_2\text{Et}$, where R = a chiral benzylic substituent, and ZnBr_2 , followed by $\text{R}'\text{ZnBr}$ leads to a chiral α -amino ester.⁸⁶⁸ Terminal alkynes add to imines using ZnCl_2 and TMSCl , and with a chiral ligand attached to nitrogen the reaction proceeds with some enantioselectivity.⁸⁶⁹

Other organometallic compounds,⁸⁷⁰ including allylic stannanes,⁸⁷¹ allylic samarium,⁸⁷² allylic germanium,⁸⁷³ and allylic indium compounds⁸⁷⁴ add to aldimines in the same manner. Aryltrialkylstannanes also add the aryl group to *N*-tosyl imines using a rhodium catalyst and sonication.⁸⁷⁵ Catalytic enantioselective addition reactions are well known,⁸⁷⁶ including reactions in an ionic liquid.⁸⁷⁷ Allylic

⁸⁷⁷In bmim BF_4 , 1-butyl-3-methylimidazolium tetrafluoroborate: Chowdari, N.S.; Ramachary, D.B.; Barbas III, C.F. *Synlett* **2003**, 1906.

halides react with imines in the presence of indium metal⁸⁷⁸ or InCl_3 ⁸⁷⁹ to give the homoallylic amine, and with *N*-sulfonyl imines to give the homoallylic sulfonamide.⁸⁸⁰ In this latter reaction, antiselectivity was observed when the reaction was done in water, and syn selectivity when done in aqueous THF.⁸⁸¹ Propargylic halides add to imines in the presence of indium metal, in aq. THF.⁸⁸² Imines react with allylic halides and gallium metal, with ultrasound.⁸⁸³ Imines also react with allylic halides and Yb, in the presence of Me_3SiCl .⁸⁸⁴ Aryl iodides add to *N*-aryl imines in the presence of a rhodium catalyst.⁸⁸⁵ Titanium enolates add to imines to give β -amino esters.⁸⁸⁶ Terminal alkynes react with aryl aldehydes and aryl amines to give propargylic amine without a catalyst,⁸⁸⁷ and an iridium⁸⁸⁸ or a copper catalyst⁸⁸⁹ also leads to a propargylic amine.⁸⁹⁰ Terminal alkynes add to imines to give a propargylic amine with high enantioselectivity using a chiral copper complex.⁸⁹¹ Triethylaluminum adds an ethyl group to an imine in the presence of a europium catalyst. Reaction with PhSnMe_3 and *N*-tosylimines with a rhodium catalyst, for example, leads to addition of a phenyl group to the carbon of the $\text{C}=\text{N}$ bond.⁸⁹² Other *N*-sulfonyl imines react similarly to give the corresponding sulfonamide, and in the presence of a chiral ligand the reaction proceeds to good enantioselectivity.⁸⁹³ *N*-Tosyl imines also react with dialkylzinc reagents, giving the sulfonamide with modest enantioselectivity.⁸⁹⁴ *N*-Sulfinyl imines, $\text{R}_2\text{CH}=\text{NS}(=\text{O})\text{R}'$,⁸⁹⁵ react with Grignard reagents (R^2MgX) to give the corresponding *N*-sulfinylamine, $\text{R}_2\text{CH}(\text{R}^2)\text{NHS}(=\text{O})\text{R}'$.⁸⁹⁶ Enolate anions, generated by reaction of dimethylaminopyridine and a conjugated ketone, add to *N*-tosylimines.⁸⁹⁷ *N*-Carbamoyl imines add acetonitrile (via carbon) using DBU and a ruthenium catalyst.⁸⁹⁸

Activated aromatic compounds add to *N*-carbamoyl imines in the presence of copper catalysts, and with good enantioselectivity when a chiral catalyst is used.⁸⁹⁹ A combination of AuCl₃/AgOTf facilitates the addition of arenes to *N*-tosyl imines.⁹⁰⁰ Furan derivatives add via C-2 with good enantioselectivity using a chiral phosphoric acid catalyst.⁹⁰¹ Alkenes add to *N*-tosyl imines with a Yb catalyst⁹⁰² and allenes add to *N*-carbamoyl imines in the presence of vanadium catalyst.⁹⁰³ *N*-Carbamoyl imines, formed *in situ*, react with allylic silanes in the presence of an iodine catalyst.⁹⁰⁴ The intramolecular addition of an alkene to an imine, facilitated by Cp₂ZrBu₂, gave a cycloalkyl amine.⁹⁰⁵

Arylboronates (p. 815) add to *N*-sulfonyl imines in the presence of a rhodium catalyst to give the corresponding sulfonamide.⁹⁰⁶ Vinyl boronates also add to nitrones in the presence of Me₂Zn, transferring the vinyl group to the C=N unit.⁹⁰⁷ Aryl boronic acids (p. 815) add the aryl group to *N*-tosyl imines using a rhodium catalyst.⁹⁰⁸ Allylic boronates also add to aldehydes, and subsequent treatment with ammonia give the homoallylic amine.⁹⁰⁹

Allylic silanes, such as allyltrimethylsilane, add to *N*-substituted imines in the presence of a palladium catalyst to give the homoallylic amine.⁹¹⁰ Similar results are obtained when the allylic silane and imine are treated with a catalytic amount of tetrabutylammonium fluoride.⁹¹¹ *N*-Tosyl imines also react with allylic silanes, and the reaction of EtO₂C–CH=NTs and allyltrimethylsilane with a chiral copper catalyst gave EtO₂C–CH(NHTs)CH₂CH=CH₂, albeit in poor yield with modest enantioselectivity.⁹¹² Another addition reaction converts aryl aldehydes to the imine using Me₂N–SiMe₃ and LiClO₄, and subsequent reaction with Me₂PhSiCl gave the corresponding amine, ArCH(SiMe₂Ph)NMe₂.⁹¹³ Allylic trichlorosilanes add to hydrazones to give homoallylic hydrazine derivatives with excellent anti-selectivity⁹¹⁴

and with good enantioselectivity using a chiral ligand.⁹¹⁵ Chiral allyl silane derivatives have been developed, and add to hydrazones with good enantioselectivity.⁹¹⁶

Aldehydes add via the α -carbon using proline, to give β -amino aldehydes with good selectivity to give chiral β -amino aldehydes.⁹¹⁷ Silyl enol ethers add to hydrazones in the presence of ZnF_2 and a chiral ligand to give chiral β -hydrazino ketones.⁹¹⁸ Nitro compounds add to *N*-carbamoyl imines with a chiral diamine catalyst with some enantioselectivity.⁹¹⁹ Nitro compounds add via carbon using a copper catalyst, and with good enantioselectivity when a chiral ligand is used.⁹²⁰ Similar addition to imine derivatives was accomplished using ketene silyl acetals and Amberlyst-15.⁹²¹ Alternatively, an imine is reacted first with $\text{Zn}(\text{OTf})_2$ and then with a ketene silyl acetal.⁹²² The conjugate bases of nitro compounds (formed by treatment of the nitro compound with BuLi) react with Grignard reagents in the presence of $\text{ClCH}=\text{NMe}_2^+ \text{Cl}^-$ to give oximes: $\text{RCH}=\text{N}(\text{O})\text{OLi} + \text{R}'\text{MgX} \rightarrow \text{RR}'\text{C}=\text{NOH}$.⁹²³

Many other $\text{C}=\text{N}$ systems (phenylhydrazones, oxime ethers, etc.) give normal addition when treated with Grignard reagents; others give reductions; others give miscellaneous reactions. Organocerium reagents add to hydrazones.⁹²⁴ Oximes can be converted to hydroxylamines (**37**) by treatment with 2 equivalents of an alkyl lithium reagent, followed by methanol.⁹²⁵ Oxime ethers add an allyl group upon reaction with allyl bromide and indium metal in water.⁹²⁶ Nitrones, $\text{R}_2\text{C}=\text{N}^+(\text{R}')-\text{O}^-$, react with allylic bromides and Sm to give homoallylic oximes,⁹²⁷ and with terminal alkynes and a zinc catalyst to give propargylic oximes.⁹²⁸

Grignard reagents also add to nitrones.⁹²⁹ Nitrones react with $\text{CH}_2=\text{CHCH}_2\text{InBr}$ in aq. DMF to give the homoallylic oxime⁹³⁰ and silyl ketene acetals add in the presence of a chiral titanium catalyst to good enantioselectivity.⁹³¹ Hydrazone derivatives react with iodoalkenes in the presence of InCl_3 and $\text{Mn}_2(\text{CO})_{10}$ under photochemical conditions to give the hydrazone derivative.⁹³² Indium metal promotes the addition of alkyl iodides to hydrazones.⁹³³ A hydrazone can be formed *in situ* by reacting an aldehyde with a hydrazine derivative, and in the presence of tetrallyltin and a scandium catalysts, homoallylic hydrazone derivatives are formed.⁹³⁴ Ketene dithioacetals add to hydrazones using a chiral zirconium catalyst to give a pyrazolidine.⁹³⁵

Radical addition to imines is known. Carbon-centered radicals add to imines.⁹³⁶ The reaction of an alkyl halide with BEt_3 in aqueous methanol, for example, gives the imine addition product, an alkylated amine.⁹³⁷ Secondary alkyl iodides add to *O*-alkyl oximes in the presence of BEt_3 and AIBN, and this methodology was used to convert $\text{MeO}_2\text{C}-\text{CH}=\text{NOBn}$ to $\text{MeO}_2\text{C}-\text{CH}(\text{R})\text{NOBn}$.⁹³⁸ Benzylic halides adds to imines under photochemical conditions, and in the presence of 1-benzyl-1,4-dihydronicotinamide⁹³⁹ or with BEt_3 in aqueous methanol.⁹⁴⁰ Tertiary alkyl iodides add to oxime ethers using $\text{BF}_3\cdot\text{OEt}_2$ in the presence of BEt_3/O_2 .⁹⁴¹

Iminium salts⁹⁴² give tertiary amines directly, with just R adding:

Chloroiminium salts $\text{ClCH}=\text{NR}'_2 \text{Cl}^-$ (generated *in situ* from an amide HCONR'_2 and phosgene COCl_2) react with 2 equivalents of a Grignard reagent RMgX , one adding to the $\text{C}=\text{N}$ and the other replacing the Cl , to give tertiary amines $\text{R}_2\text{CHNR}'_2$.⁹⁴³

16-32 Addition of Carbenes and Diazoalkanes to C=N Compounds

In the presence of metal catalysts such as $\text{Yb}(\text{OTf})_3$, diazoalkanes add to imines to generate aziridines. An example is:⁹⁴⁴

The reaction is somewhat selective for the *cis*-diastereomer. The use of chiral additives in this reaction leads to aziridines enantioselectively.⁹⁴⁵ Imines can be formed by the reaction of an aldehyde and an amine, and subsequent treatment with Me_3SiI and butyllithium gives an aziridine.⁹⁴⁶ *N*-Tosyl imines react with diazoalkenes to form *N*-tosyl aziridines, with good *cis*-selectivity⁹⁴⁷ and modest enantioselectivity in the presence of a chiral copper catalyst,⁹⁴⁸ but excellent enantioselectivity with a chiral rhodium catalyst.⁹⁴⁹ It is noted that *N*-tosyl aziridines are formed by the reaction of an alkene with $\text{PhI}=\text{NTs}$ and a copper catalyst.⁹⁵⁰ The reaction of alkenes with diazo compounds is discussed in **15-53**.

16-33 The Addition of Grignard Reagents to Nitriles and Isocyanates**Alkyl,oxo-de-nitrilo-tersubstitution** (Overall transformation)***N*-Hydro-*C*-alkyl-addition**

Ketones can be prepared by addition of Grignard reagents to nitriles, followed by hydrolysis of the initially formed imine anion. Many ketones have been made in this manner, though when both R groups are alkyl, yields are not high.⁹⁵¹ Yields

can be improved by the use of Cu(I) salts⁹⁵² or by using benzene containing one equivalent of ether as the solvent, rather than ether alone.⁹⁵³ The ketimine salt does not in general react with Grignard reagents: Hence tertiary alcohols or tertiary alkyl amines are not often side products.⁹⁵⁴ By careful hydrolysis of the salt it is sometimes possible to isolate ketimines,⁹⁵⁵

especially when R and R' = aryl. The addition of Grignard reagents to the C≡N group is normally slower than to the C=O group, and cyano group containing aldehydes add the Grignard reagent without disturbing the CN group.⁹⁵⁶ Other metal compounds have been used, including Sm with allylic halides⁹⁵⁷ and organocerium compounds such as MeCeCl₂.⁹⁵⁸ Allylic halides react with an excess of zinc metal in the presence of 40% AlCl₃, and in the presence of a nitrile homoallylic ketones are produced after hydrolysis.⁹⁵⁹ Benzonitrile reacts as with iodopropane and a mixture of SmI₂ and NiI₂ catalysts to give 1-phenyl-1-butanone.⁹⁶⁰

Addition of Grignard reagents⁹⁶¹ or organolithium reagents⁹⁶² to ω-halo nitriles leads to 2-substituted cyclic imines.

The following mechanism has been proposed for the reaction of the methyl Grignard reagent with benzonitrile:⁹⁶³

Arenes add to nitriles in the presence of a palladium catalyst in DMSO/trifluoroacetic acid to give a diaryl ketone.⁹⁶⁴

The addition of Grignard reagents to isocyanates gives, after hydrolysis, *N*-substituted amides.⁹⁶⁵ This is a very good reaction and can be used to prepare

G. Carbon Attack by Active Hydrogen Compounds

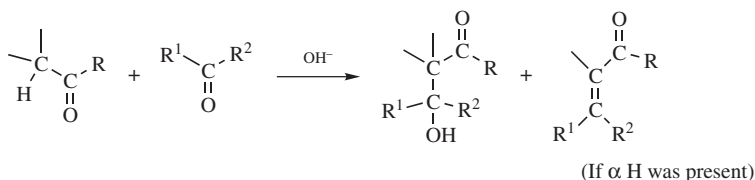

Reactions 16-34–16-50 are base-catalyzed condensations (although some of them are also catalyzed to acids).⁹⁶⁹ In 16-34–16-44, a base removes a C–H proton to give a carbanion, which then adds to a C=O. The oxygen acquires a proton, and the resulting alcohol may or may not be dehydrated, depending on whether an α hydrogen is present and on whether the new double bond would be in conjugation with double bonds already present:

The reactions differ in the nature of the active hydrogen component and the carbonyl component. Table 16.2 illustrates the differences. Reaction 16-50 is an analogous reaction involving addition to $C\equiv N$.

16-50	Nitrile 	Nitrile	
Thorpe reaction			

In the *aldol reaction*,⁹⁷¹ the α carbon of one aldehyde or ketone molecule adds to the carbonyl carbon of another.⁹⁷² Although acid-catalyzed aldol reactions are known,⁹⁷³ the most common form of the reaction uses a base. There is evidence that an SET mechanism can intervene when the substrate is an aromatic ketone.⁹⁷⁴ Although hydroxide was commonly used in early versions of this reaction, stronger bases, such as alkoxides (RO^-) or amides (R_2N^-), are also common. Amine bases have been used.⁹⁷⁵ Hydroxide ion is not a strong enough base to convert substantially all of an aldehyde or ketone molecule to the corresponding enolate ion, that is., the equilibrium lies well to the left, for both aldehydes and

ketones. Nevertheless, enough enolate ion is present for the reaction to proceed:

⁹⁷¹This reaction is also called the *aldol condensation*, though, strictly speaking, this term applies to the formation only of the α,β -unsaturated product, and not the aldol.

⁹⁷²For reviews, see Thebtaranonth, C.; Thebtaranonth, Y., in Patai, S.; Rappoport, Z. *The Chemistry of Enones*, pt. 1, Wiley, NY, **1989**, pp. 199–280, 199–212; Hajos, Z.G., in Augustine, R.L. *Carbon–Carbon Bond Formation*, Vol. 1; Marcel Dekker, NY, **1979**; pp. 1–84; Nielsen, A.T.; Houlihan, W.J. *Org. React.* **1968**, *16*, 1.

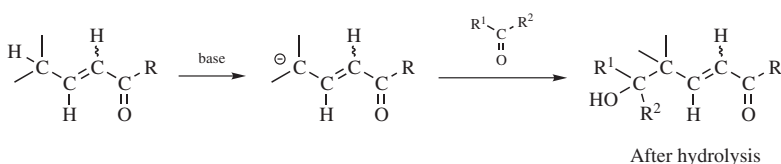

⁹⁷³For example, see Mahrwald, R.; Gündogan, B. *J. Am. Chem. Soc.* **1998**, *120*, 413.

⁹⁷⁴Ashby, E.C.; Argyropoulos, J.N. *J. Org. Chem.* **1986**, *51*, 472.

⁹⁷⁵Trost, B.M.; Silcoff, E.R.; Ito, H. *Org. Lett.* **2001**, *3*, 2497.

This equilibrium lies further to the right with alkoxide and especially with amide bases, depending on the solvent. Protic solvents, such as water or alcohol, are acidic enough to react with the enolate anion and shift the equilibrium to the left. In an aprotic solvent, such as ether or THF, with a strong amide base, such as lithium diisopropylamide (LDA, p. 389), the equilibrium lies more to the right.⁹⁷⁶ A variety of amide bases can be used to deprotonate the ketone or aldehyde, and in the case of an unsymmetrical ketone removal of the more acidic proton leads to the kinetic enolate anion.⁹⁷⁷ Note that a polymer-bound amide base has been used⁹⁷⁸ and solid-phase chiral lithium amides are known.⁹⁷⁹ A polymer-supported phosphoramidate has been used as a catalyst for the aldol condensation.⁹⁸⁰ The product is a β -hydroxy aldehyde (called an *aldol*) or ketone, which in some cases is dehydrated during the course of the reaction. In aprotic solvents with a mild workup procedure, however, the aldol is readily isolated unless the substrate is an aromatic aldehyde or ketone. The aldol reaction has been done in ionic liquids.⁹⁸¹ Even if the dehydration is not spontaneous, it can usually be done easily, since the new double bond is in conjugation with the C=O bond; so that this is a method of preparing α,β -unsaturated aldehydes and ketones, as well as β -hydroxy aldehydes and ketones. One-pot procedures have been reported to give the conjugated product.⁹⁸² The entire reaction is an equilibrium (including the dehydration step), and α,β -unsaturated and β -hydroxy aldehydes and ketones can be cleaved by treatment with ^-OH (the *retrograde aldol reaction*). The *retro*-aldol condensation has been exploited for crossed-aldol reactions.⁹⁸³ A vinylogous aldol reaction is known⁹⁸⁴ as is a 1 “double” aldol.⁹⁸⁵ Enzyme-mediated aldol reactions have been reported using two aldehydes, including formaldehyde.⁹⁸⁶

Under the principle of vinylogy, the active hydrogen can be one in the γ position of an α,β -unsaturated carbonyl compound:

⁹⁸⁵For a discussion of the mechanism of this reaction see Abiko, A.; Inoue, T.; Masamune, S. *J. Am. Chem. Soc.* **2002**, *124*, 10759.

⁹⁸⁶Demir, A.S.; Ayhan, P.; Iğdir, A.C.; Duygu, A.N. *Tetrahedron* **2004**, *60*, 6509.

The scope of the aldol reaction may be discussed under five headings:

1. *Reaction between Two Molecules of the Same Aldehyde.* Hydroxide or alkoxide bases are used in protic solvents,⁹⁸⁷ and the reaction is quite feasible. Many aldehydes have been converted to aldols and/or their dehydration products in this manner. The most effective catalysts are basic ion-exchange resins. Of course, the aldehyde must possess an α hydrogen.
2. *Reaction between Two Molecules of the Same Ketone.* With hydroxide or alkoxide bases in protic solvents the equilibrium lies well to the left,⁹⁸⁸ and the reaction is feasible only if the equilibrium can be shifted. This can often be done by allowing the reaction to proceed in a Soxhlet extractor (e.g., see OS I, 199). Two molecules of the same ketone can also be condensed without a Soxhlet extractor,⁹⁸⁹ by treatment with basic Al_2O_3 .⁹⁹⁰ Unsymmetrical ketones condense on the side that has more hydrogens. An exception is butanone, which reacts at the CH_2 group with acid catalysts, though with basic catalysts, it too reacts at the CH_3 group.

Alternatively, the use of an amide base, such as LDA or lithium hexamethyldisilazide (p. 389), in aprotic solvents, such as ether or THF, at low temperatures, generates an enolate anion under conditions where the equilibrium lies more to the right. A second equivalent of the ketone can then be added. Clearly, this technique is effective in reactions of aldehydes.

3. *Reaction between Two Different Aldehydes.* In the most general case, this will produce a mixture of four products (eight, if the alkenes are counted). However, if one aldehyde does not have an α hydrogen, only two aldols are possible, and in many cases the crossed product is the main one. The crossed-aldol reaction is often called the *Claisen–Schmidt reaction*.⁹⁹¹ The crossed aldol is readily accomplished using amide bases in aprotic solvent. The first aldehyde is treated with LDA in THF at -78°C , for example, to form the enolate anion. Subsequent treatment with a second aldehyde leads to the mixed aldol product. The crossed aldol of two aldehydes has been done using potassium *tert*-butoxide and $\text{Ti}(\text{OBu})_4$.⁹⁹²
4. *Reaction between Two Different Ketones.* This is seldom attempted with hydroxide or alkoxide bases in protic solvents since similar considerations apply to those discussed for aldehydes. This reaction is commonly done with amide bases in aprotic solvents, but with somewhat more difficulty than with aldehydes.

⁹⁸⁷For discussions of equilibrium constants in aldol reactions, see Guthrie, J.P.; Wang, X. *Can. J. Chem.* **1991**, *69*, 339; Guthrie, J.P. *J. Am. Chem. Soc.* **1991**, *113*, 7249, and references cited therein.

⁹⁸⁸The equilibrium concentration of the product from acetone in pure acetone was determined to be 0.01%: Maple, S.R.; Allerhand, A. *J. Am. Chem. Soc.* **1987**, *109*, 6609.

⁹⁸⁹For another method, see Barot, B.C.; Sullins, D.W.; Eisenbraun, E.J. *Synth. Commun.* **1984**, *14*, 397.

⁹⁹⁰Muzart, J. *Synthesis* **1982**, 60; *Synth. Commun.* **1985**, *15*, 285.

⁹⁹¹For an aqueous version, see Buonora, P.T.; Rosauer, K.G.; Dai, L. *Tetrahedron Lett.* **1995**, *36*, 4009.

⁹⁹²Han, Z.; Yorimitsu, H.; Shinokubo, H.; Oshima, K. *Tetrahedron Lett.* **2000**, *41*, 4415.

5. *Reaction between an Aldehyde and a Ketone.* This is usually feasible with hydroxide or alkoxides bases in protic solvents, particularly when the aldehyde has no α hydrogen, since there is no competition from ketone condensing with itself.⁹⁹³ This is also called the *Claisen–Schmidt reaction*. Even when the aldehyde has an α hydrogen, it is generally the α carbon of the ketone that adds to the carbonyl of the aldehyde, not the other way around. Mixtures are usually produced, however. If the ketone or the aldehyde is treated with an amide base in aprotic solvents, a second aldehyde or ketone can be added to give the aldolate with high regioselectivity. The reaction can be also made regioselective by preparing an enol derivative of the ketone separately⁹⁹⁴ and then adding this to the aldehyde (or ketone). Other types of preformed derivatives that react with aldehydes and ketones are enamines (with a Lewis acid catalyst),⁹⁹⁵ and enol borinates $R'CH=CR^2-OBR_2$ ⁹⁹⁶ (which can be synthesized by **15-27**) or directly from an aldehyde or ketone⁹⁹⁷). Preformed metallic enolates are also used. For example, lithium enolates⁹⁹⁸ (prepared by **12-23**) react with the substrate in the presence of $ZnCl_2$;⁹⁹⁹ in this case the aldol product is stabilized by chelation of its two oxygen atoms with the zinc ion.¹⁰⁰⁰ Other metallic enolates can be used for aldol reactions, either preformed or generated *in situ* with a catalytic amount of a metal compound. Metals used for this purpose include Mg,¹⁰⁰¹ Ti,¹⁰⁰² Zr,¹⁰⁰³ Pd,¹⁰⁰⁴

⁹⁹³For a study of the rate and equilibrium constants in the reaction between acetone and benzaldehyde, see Guthrie, J.P.; Cossar, J.; Taylor, K.F. *Can. J. Chem.* **1984**, *62*, 1958. In,¹⁰⁰⁵ Sn,¹⁰⁰⁶ La,¹⁰⁰⁷ and Sm,¹⁰⁰⁸ all of which give products with moderate to excellent diastereoselectivity¹⁰⁰⁹ and regioselectivity. α -Alkoxy ketones react with lithium enolates particularly rapidly.¹⁰¹⁰ A bis(aldol) condensation has been reported with epoxy ketones and aldehydes using SmI₂.¹⁰¹¹ Vinyl silanes react with aldehydes in the presence of a copper catalyst to give the aldol product.¹⁰¹²

The reactions with preformed enol derivatives provide a way to control the stereoselectivity of the aldol reaction.¹⁰¹³ As with the Michael reaction (15-24), the aldol reaction creates two new stereogenic centers, and, in the most general case, there are four stereoisomers of the aldol product (two racemic diastereomers), which can be represented as

Among the preformed enol derivatives used for diastereoselective aldol condensations have been enolates of Li,¹⁰¹⁴ Mg, Ti,¹⁰¹⁵ Zr,³⁴³ and Sn,¹⁰¹⁶ silyl enol

ethers,¹⁰¹⁷ enol borinates,¹⁰¹⁸ and enol borates $R'CH=CR^2-OB(OR)_2$.¹⁰¹⁹ The nucleophilicity of silyl enol ethers has been examined.¹⁰²⁰ Base-induced formation of the enolate anion generally leads to a mixture of (*E*)- and (*Z*)-isomers, and dialkyl amide bases are used in most cases. The (*E/Z*) stereoselectivity depends on the structure of the lithium dialkylamide base, with the highest (*E/Z*) ratios obtained with LiTMP-butyllithium mixed aggregates in THF.¹⁰²¹ The use of LiHMDS resulted in a reversal of the (*E/Z*) selectivity. In general, metallic (*Z*) enolates give the syn (or erythro) pair, and this reaction is highly useful for the diastereoselective synthesis of these products.¹⁰²² The (*E*) isomers generally react nonstereoselectively. However, anti (or threo) stereoselectivity has been achieved in a number of cases, with titanium enolates,¹⁰²³ with magnesium enolates,¹⁰²⁴ with certain enol borinates,¹⁰²⁵ and with lithium enolates at -78°C .¹⁰²⁶ Enolization accounts for syn–anti isomerization of aldols.¹⁰²⁷ In another variation, a β -keto Weinreb amide (see **16-82**) reacted with $TiCl_4$ and Hünig's base ($iPr_2N\text{Et}$) and then an aldehyde to give the β -hydroxy ketone.¹⁰²⁸

in catalytic reactions. Aldehydes are condensed with ketones with potassium hexamethyldisilazide (KHMDs) and 8% of a chiral lithium catalyst, giving the aldol product with moderate enantioselectivity.¹⁰⁴³ Structural variations in the aldehyde or ketone are compatible with many enantioselective condensation reactions. An α -hydroxy ketone was condensed with an aldehyde using a chiral zinc catalyst to give the aldol (an α,β -dihydroxy ketone) with good syn selectivity and good enantioselectivity.¹⁰⁴⁴ A catalytic amount of a nicotine metabolite allows an enantioselective reaction in aqueous media.¹⁰⁴⁵ Chiral vinylogous aldol reactions have been reported.¹⁰⁴⁶

Silyl enol ethers react with aldehydes in the presence of chiral boranes¹⁰⁴⁷ or other additives¹⁰⁴⁸ to give aldols with good asymmetric induction (see the Mukaiyama aldol reaction in **16-35**). Chiral boron enolates have been used.¹⁰⁴⁹ Since both new stereogenic centers are formed enantioselectively, this kind of process is called *double asymmetric synthesis*.¹⁰⁵⁰ Where both the enolate derivative and substrate were achiral, carrying out the reaction in the presence of an optically active boron compound¹⁰⁵¹ or a diamine coordinated with a tin compound¹⁰⁵² gives the aldol product with excellent enantioselectivity for one stereoisomer. Formation of the magnesium enolate anion of a chiral amide, adds to aldehydes to give the alcohol enantioselectively.¹⁰⁵³

Diamine protonic acids have been used for catalytic asymmetric aldol reaction.¹⁰⁵⁴ Boron triflate derivatives, R₂BOTf, have been used for the condensation of ketals and ketone to give β -alkoxy ketones.¹⁰⁵⁵

It is possible to make the α carbon of the aldehyde add to the carbonyl carbon of the ketone, by using an imine instead of an aldehyde, and $\text{LiN}(i\text{Pr})_2$ as the base.¹⁰⁵⁶

This is known as a *directed aldol reaction*. Similar reactions have been performed with α -lithiated dimethylhydrazones of aldehydes or ketones¹⁰⁵⁷ and with α -lithiated aldoximes.¹⁰⁵⁸

The aldol reaction can also be performed with acid catalysts, as mentioned above, in which case dehydration usually follows. Here, there is initial protonation of the carbonyl group, which attacks the α carbon of the *enol* form of the other molecule.¹⁰⁵⁹

With respect to the enol, this mechanism is similar to that of halogenation (12-4). A side reaction that is sometimes troublesome is further condensation, since the product of an aldol reaction is still an aldehyde or ketone. The aldol condensation of aldehydes has also been done using a mixture of pyrrolidine and benzoic acid.¹⁰⁶⁰

The intramolecular aldol condensation is well known, and aldol reactions are often used to close five- and six-membered rings. Because of the favorable entropy (p. 303), such ring closures generally take place with ease¹⁰⁶¹ when using hydroxide or alkoxide bases in protic solvents. In aprotic solvents with amide bases,

¹⁰⁵⁹There is evidence (in the self-condensation of acetaldehyde) that a water molecule acts as a base (even in concentrated H_2SO_4) in assisting the addition of the enol to the protonated aldehyde: Baigrie, L.M.; Cox, R.A.; Slebocka-Tilk, H.; Tencer, M.; Tidwell, T.T. *J. Am. Chem. Soc.* **1985**, *107*, 3640.

¹⁰⁶¹For rate and equilibrium constants, see Guthrie, J.P.; Guo, J. *J. Am. Chem. Soc.* **1996**, *118*, 11472. For neighboring-group effects, see Eberle, M.K. *J. Org. Chem.* **1996**, *61*, 3844.

formation of the enolate anion occurs by deprotonation of the more acidic site, followed by cyclization to the second carbonyl. The acid-catalyzed intramolecular aldol condensation is known, and the mechanism has been studied.¹⁰⁶² Stereoselective proline-catalyzed intramolecular aldol reactions give the cyclize product with good enantioselectivity.¹⁰⁶³

An important extension of the intramolecular aldol condensation is the *Robinson annulation* reaction,¹⁰⁶⁴ which has often been used in the synthesis of steroids and terpenes. In original versions of this reaction, a cyclic ketone is converted to another cyclic ketone under equilibrium conditions using hydroxide or alkoxide bases in a protic solvent, forming one additional six-membered ring containing a double bond. The reaction can be done in a stepwise manner using amide bases in aprotic solvents. In the reaction with hydroxide or alkoxide bases in alcohol or water solvents, the substrate is treated with methyl vinyl ketone (or a simple derivative of methyl vinyl ketone) and a base.¹⁰⁶⁵ The enolate ion of the substrate adds to the methyl vinyl ketone in a Michael reaction (**15-24**) to give a diketone that undergoes or is made to undergo an internal aldol

reaction and subsequent dehydration to give the product.¹⁰⁶⁶ The Robinson annulation can be combined with alkylation.¹⁰⁶⁷ Enantioselective Robinson annulation techniques have been developed, including a proline-catalyzed reaction.¹⁰⁶⁸ The Robinson annulation has been done in ionic liquids¹⁰⁶⁹ and a solvent-free version of the reaction is known.¹⁰⁷⁰

Because methyl vinyl ketone has a tendency to polymerize, precursors are often used instead, that is., compounds that will give methyl vinyl ketone when treated with a base. One common example, $\text{MeCOCH}_2\text{CH}_2\text{NEt}_2\text{Me}^+ \text{I}^-$ (see **17-9**), is easily prepared by quaternization of $\text{MeCOCH}_2\text{CH}_2\text{NEt}_2$, which itself is prepared

by a Mannich reaction (**16-19**) involving acetone, formaldehyde, and diethylamine. α -Silylated vinyl ketones $\text{RCOC}(\text{SiMe}_3)=\text{CH}_2$ have also been used successfully in annulation reactions.¹⁰⁷¹ The SiMe_3 group is easily removed. 1,5-Diketones prepared in other ways are also frequently cyclized by internal aldol reactions. When the ring closure of a 1,5-diketone is catalyzed by the amino acid (*S*)-proline, the product is optically active with high enantiomeric excess.¹⁰⁷² *Stryker's reagent* $^{1073}[(\text{Ph}_3\text{P})\text{CuH}]_6$ has been used for an intramolecular addition where ketone enolate anion to a conjugated ketone, giving cyclic alcohol with a pendant ketone unit.¹⁰⁷⁴

16-35 Mukaiyama Aldol and Related Reactions¹⁰⁷⁵

O-Hydro-*C*-(α -acylalkyl)-addition

An important variation of the aldol condensation involves treatment of an aldehyde or ketone with a silyl ketene acetal $\text{R}_2\text{C}=\text{C}(\text{OSiMe}_3)\text{OR}$ ¹⁰⁷⁶ in the presence of TiCl_4 ¹⁰⁷⁷, to give **38**. The silyl ketene acetal can be considered a preformed enolate that gives aldol product

with TiCl_4 in aqueous solution, or with no catalyst at all.¹⁰⁷⁸ A combination of TiCl_4 and a *N*-tosyl imine has also been used to facilitate the Mukaiyama aldol

$\text{RCH}=\text{CH}(\text{OTMS})\text{SiMe}_3$ react with acetals in the presence of SnCl_4 to give β -alkoxy silyl ketones.¹¹⁰⁴

An interesting variation in this reaction combined an intermolecular Mukaiyama aldol followed by an intramolecular reaction (a “domino” Mukaiyama aldol) that gave cyclic conjugated ketone products.¹¹⁰⁵ Borane derivatives such as $\text{C}=\text{C}-\text{OB}(\text{NMe}_2)_2$ react with aldehydes to give β -amino ketones.¹¹⁰⁶

Silyl enol ethers¹¹⁰⁷ derived from esters (silyl ketene acetals) react with aldehydes in the presence of various catalysts to give β -hydroxy esters. Water accelerates the reaction of an aldehyde and a ketene silyl acetal with no other additives.¹¹⁰⁸ The reaction is catalyzed by triphenylphosphine¹¹⁰⁹ and also by SiCl_4 with a chiral bis(phosphoramidate) catalyst.¹¹¹⁰ The reaction was done without a catalyst in an ionic liquid.¹¹¹¹ A vinylogous reaction is known that gives δ -hydroxy- α,β -unsaturated esters.¹¹¹² Under different conditions, silyl ketene acetals of conjugated esters react with aldehydes to give conjugated lactones.¹¹¹³ Imines react with silyl ketene acetals in the presence of SmI_2 to give β -amino esters.¹¹¹⁴ Another variation converted a *N*-(1-trimethylsilyloxyvinyl) imine to a conjugated amide by initial reaction with 2 equivalents of *n*-butyllithium and a zirconium complex followed by reaction with an aldehyde.¹¹¹⁵ Silyl ketene acetals also undergo conjugate addition in reactions with conjugated ketones.¹¹¹⁶ Silyl ketene acetals of thio esters also react with aldehydes to give β -hydroxy thioesters.¹¹¹⁷

Asymmetric Mukaiyama aldol reactions and reactions of silyl ketene acetals have been reported,¹¹¹⁸ usually using chiral additives¹¹¹⁹ although chiral auxiliaries

have also been used.¹¹²⁰ Chiral catalysts, usually transition-metal complexes using chiral ligands, are quite effective,¹¹²¹ but chiral bis(oxazolones)¹¹²² and chiral quaternary ammonium salts¹¹²³ have also been used. A zirconium BINOL complex gave good enantioselectivity in reactions of silyl ketene acetals, and also good anti selectivity in the product.¹¹²⁴ This reaction can also be run with the aldehyde or ketone in the form of its acetal $R^3R^4C(OR')_2$, in which case the product is the ether $R^1COCHR_2CR^3R^4OR'$ instead of **38**.¹¹²⁵ Trichlorosilyl enol ethers react with aldehydes directly in the presence of a chiral phosphoramidate to give the aldol with good syn selectivity and good enantioselectivity.¹¹²⁶ Vinylogous silyl ketene acetals with a chiral oxazolidinone auxiliary attached to the α -vinylic carbon react with aldehydes and $TiCl_4$ to give a δ -hydroxy- α,β -unsaturated amide (an acyl oxazolidinone).¹¹²⁷

Enol acetates and enol ethers also give this product when treated with acetals and $TiCl_4$ or a similar catalyst.¹¹²⁸ A variation of this condensation uses an enol acetate with an aldehyde in the presence of Et_2AlOEt to give the aldol product.¹¹²⁹

In the presence of a strong base, the α carbon of a carboxylic ester or other acid derivative can condense with the carbonyl carbon of an aldehyde or ketone to give a β -hydroxy ester,¹¹³⁰ amide, and so on., which may or may not be dehydrated to the α,β -unsaturated derivative. This reaction is sometimes called the *Claisen reaction*,¹¹³¹ an unfortunate usage since that name is more firmly connected to **16-85**. Early reactions used hydroxide or an alkoxide base in water or alcohol solvents, where self-condensation was the major process. Under such conditions, the aldehyde or ketone was usually chosen for its lack of an α -proton. Much better control of the reaction was achieved when amide bases in aprotic solvents, such as ether or THF, were used. The reaction of *tert*-butyl acetate and LDA¹¹³² in hexane or more commonly THF at -78°C gives the enolate anion of *tert*-butyl acetate,¹¹³³ (**12-23**, e.g., although self-condensation is occasionally a problem even here. Subsequent reaction a ketone provides a simple rapid alternative to the Reformatsky reaction (**16-28**) as a means of preparing β -hydroxy *tert*-butyl esters. It is also possible for the α carbon of an aldehyde or ketone to add to the carbonyl carbon of a carboxylic ester, but this is a different reaction (**16-86**) involving nucleophilic substitution and not addition to a C=O bond. It can, however, be a side reaction if the aldehyde or ketone has an α hydrogen.

Transition-metal mediated condensation of esters and aldehydes is known. The reaction of a thioester and an aryl aldehyde with $\text{TiCl}_4\text{-NBu}_3$, for example, gave a β -hydroxy thioester with good syn selectivity.¹¹³⁴ Selenoamides $[\text{RCH}_2\text{C(=Se)NR}'_2]$ react with LDA and then an aldehyde to give β -hydroxy selenoamides.¹¹³⁵

Besides ordinary esters (containing an α hydrogen), the reaction can also be carried out with lactones and, as in **16-34**, with the γ position of α,β -unsaturated esters (vinylogy). The enolate anion of an amide can be condensed with an aldehyde.¹¹³⁶

There are a number of variations of the condensation reaction of acid derivatives. The reaction between a cyclic ketone having a pendant alkynyl ester unit and tetrabutylammonium fluoride leads to cyclization to a bicyclic alcohol with an exocyclic allene moiety.¹¹³⁷ A chain-extension reaction culminates in acyl addition of an ester enolate. The reaction of a β -keto ester, such as methyl 3-oxobutanate and EtZnCH_2I , leads to chain extension via a carbenoid-like insertion reaction (p. 803), which reacts with an aldehyde in a second step to give a methyl 3-oxopentanoate derivative with a $-\text{CH(OH)R}$ group at C-2 relative to the ester carbonyl.¹¹³⁸

¹¹³⁰If the reagent is optically active because of the presence of a chiral sulfoxide group, the reaction can be enantioselective. For a review of such cases, see Solladié, G. *Chimia* **1984**, *38*, 233.

¹¹³¹Because it was discovered by Claisen, L. *Ber.* **1890**, *23*, 977.

For most esters, a much stronger base is needed than for aldol reactions; (*i*Pr)₂NLi (LDA, p. 389), Ph₃CNa and LiNH₂ are among those employed. However, one type of ester reacts more easily, and such strong bases are not needed: diethyl succinate and its derivatives condense with aldehydes and ketones in the presence of bases such as NaOEt, NaH, or KOCMe₃. This reaction is called the *Stobbe condensation*.¹¹³⁹ One of the ester groups (sometimes both) is hydrolyzed in the course of the reaction. The following mechanism accounts for (1) the fact the succinic esters react so much better than others; (2) one ester group is always cleaved; and (3) the alcohol is not the product but the alkene. In addition, intermediate lactones **39** have been isolated from the mixture.¹¹⁴⁰ The Stobbe condensation has been extended to di-*tert*-butyl esters of glutaric acid.¹¹⁴¹ The boron-mediated reaction is known.¹¹⁴²

Chiral additives, such as diazaborolidines can be added to an ester, and subsequent treatment with a base and then an aldehyde leads to a chiral β-hydroxy ester.¹¹⁴³ A variety of chiral amide or oxazolidinone derivatives have been used to form amide linkages to carboxylic acid derivatives. These chiral auxiliaries lead to chirality transfer from the enolate anion of such derivatives, in both alkylation reactions and acyl substitution reactions with aldehydes and ketones. The so-called Evans auxiliaries (**40–42**) are commonly used and give good enantioselectivity.¹¹⁴⁴ A variation is the magnesium halide-catalyzed anti-aldol reaction of chiral *N*-acylthiazolidinethiones (see **43**).¹¹⁴⁵ The use of chiral *N*-acyloxazolidinethiones with TiCl₄ and sparteine also gave good selectivity in the acyl addition.¹¹⁴⁶ Chiral diazaboron derivatives have also been used to facilitate the condensation of an α-phenylthio ester with an aldehyde.¹¹⁴⁷

16-37 The Henry Reaction¹¹⁴⁹

When aliphatic nitro compounds are used instead of aldehydes or ketones, no reduction occurs, and the reaction has been referred to as a Tollens' reaction (see **16-43**). However, the classical condensation of an aliphatic nitro compound with an aldehyde or ketone is usually called the *Henry reaction*¹¹⁵⁰ or the *Kamlet reaction*, and is essentially a nitro aldol reaction. A variety of conditions have been reported, including the use of a silica catalyst,¹¹⁵¹ Mg–Al hydrotalcite,¹¹⁵² a tetraalkylammonium hydroxide,¹¹⁵³ proazaphosphatranes,¹¹⁵⁴ or an ionic liquid.¹¹⁵⁵ A solvent free Henry reaction was reported in which a nitroalkane and an aldehyde were reacted on KOH powder.¹¹⁵⁶ Potassium phosphate has been used with nitromethane and aryl aldehydes.¹¹⁵⁷ The Henry reaction has been done using ZnEt₂ and 20% ethanolamine.¹¹⁵⁸ A gel-entrapped base has been used to catalyze this reaction.¹¹⁵⁹

Catalytic enantioselective Henry reactions are known,¹¹⁶⁰ such as the use of a chiral copper catalyst¹¹⁶¹ or a zinc catalyst.¹¹⁶² The Henry reaction of nitromethane on a chiral aldehyde under high pressure gives the β -nitro alcohol with excellent enantioselectivity.¹¹⁶³

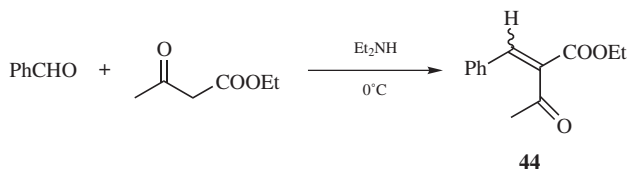

A variation of this reaction converts nitro compounds to nitronates $\text{RCH}=\text{N}^+(\text{OTMS})-\text{O}^-$, which react with aldehydes in the presence of a copper catalyst to give the β -nitro alcohol.¹¹⁶⁴

16-38 The Knoevenagel Reaction

Bis(ethoxycarbonyl)methylene-de-oxo-bisubstitution, and so on

The condensation of aldehydes or ketones, usually not containing an α hydrogen, with compounds of the form $\text{Z}-\text{CH}_2-\text{Z}'$ or $\text{Z}-\text{CHR}-\text{Z}'$ is called the *Knoevenagel reaction*.¹¹⁶⁵ Both Z and Z' may be CHO, COR, COOH, COOR, CN, NO₂, SOR, SO₂R, SO₂OR, or similar groups. Such compounds have a significantly higher enol content¹¹⁶⁶ and the α -proton is much more acidic (Table 8.1 on p. 360). When Z = COOH, decarboxylation of the product often takes place *in situ*.¹¹⁶⁷ If a strong enough base is used, the reaction can be performed on compounds possessing only a single Z (e.g., CH₃Z or RCH₂Z). Other active hydrogen compounds can also be employed, among them CHCl₃, 2-methylpyridines, terminal acetylenes, cyclopentadienes, and so on.; in fact any compound that contains a C–H bond the hydrogen of which can be removed by a base. As shown in the example, the reaction of β -keto esters and aldehydes to give **44** is promoted by diethylamine at 0°C. Nitroalkanes¹¹⁴⁹ as well as β -keto sulfoxides¹¹⁶⁸ undergo the reaction.

As with **16-34**, these reactions have sometimes been performed with acid catalysts.¹¹⁶⁹ Ionic liquid solvents have been used,¹¹⁷⁰ and heating on quaternary ammonium salts without solvent leads to a Knoevenagel reaction.¹¹⁷¹ Other solvent-free reactions are known.¹¹⁷² Ultrasound has been used to promote the reaction,¹¹⁷³ and it has also been done using microwave irradiation¹¹⁷⁴ or on silica,¹¹⁷⁵ with microwave irradiation. Another solid-state variation is done on moist LiBr,¹¹⁷⁶ heating with sodium carbonate and molecular sieves 4 Å promotes the reaction,¹¹⁷⁷ as do zeolites.¹¹⁷⁸ High-pressure conditions have been used.¹¹⁷⁹ Transition-metal compounds such as palladium complexes,¹¹⁸⁰ SmI₂¹¹⁸¹ or BiCl₃¹¹⁸² have been used to promote the Knoevenagel reaction.

In the reaction with terminal acetylenes,¹¹⁸³ sodium acetylides are the most common reagents (when they are used, the reaction is often called the *Nef reaction*), but lithium,¹¹⁸⁴ magnesium, and other metallic acetylides have also been used. A particularly convenient reagent is lithium acetylide–ethylenediamine complex,¹¹⁸⁵ a stable, free-flowing powder that is commercially available. Alternatively, the substrate may be treated with the alkyne itself in the presence of

¹¹⁶⁹For example, see Rappoport, Z.; Patai, S. *J. Chem. Soc.* **1962**, 731.

a base, so that the acetylide is generated *in situ*. This procedure is called the *Favorskii reaction*, not to be confused with the Favorskii rearrangement (**18-7**).¹¹⁸⁶

With most of these reagents the alcohol is not isolated (only the alkene) if the alcohol has a hydrogen in the proper position.¹¹⁸⁷ However, in some cases the alcohol is the major product. A β -keto allylic ester was shown to react with an aldehyde to give a β -hydroxy ketone, with loss of the allyl ester moiety, upon treatment with YbCl_3 and a palladium catalyst.¹¹⁸⁸ With suitable reactants, the Knoevenagel reaction, like the aldol (**16-2**), has been carried out diastereoselectively¹¹⁸⁹ and enantioselectively.¹¹⁹⁰ When the reactant is of the form $\text{ZCH}_2\text{Z}'$, aldehydes react much better than ketones and few successful reactions with ketones have been reported. However, it is possible to get good yields of alkene from the condensation of diethyl malonate, $\text{CH}_2(\text{COOEt})_2$, with ketones, as well as with aldehydes, if the reaction is run with TiCl_4 and pyridine in THF.¹¹⁹¹ In reactions with $\text{ZCH}_2\text{Z}'$, the catalyst is most often a secondary amine (piperidine is the most common, but see formation of **44**), though many other catalysts have been used. When the catalyst is pyridine (to which piperidine may or may not be added) the reaction is known as the *Doebner modification* of the Knoevenagel reaction and the product is usually the conjugated acid **45**. Alkoxides are also common catalysts. Microwave-induced Doebner condensation reactions are known.¹¹⁹²

A number of special applications of the Knoevenagel reaction follow:

1. The dilithio derivative of *N*-methanesulfinyl-*p*-toluidine¹¹⁹³ (**46**) adds to aldehydes and ketones to give, after hydrolysis, the hydroxysulfinamides

¹¹⁸⁶For a discussion of the mechanism of the Favorskii addition reaction, see Kondrat'eva, L.A.; Potapova, I.M.; Grigina, I.N.; Glazunova, E.M.; Nikitin, V.I. *J. Org. Chem. USSR* **1976**, *12*, 948.

¹¹⁹⁷For reviews of α -metalated isocyanides, see Schöllkopf, U. *Pure Appl. Chem.* **1979**, *51*, 1347; *Angew. Chem. Int. Ed.* **1977**, *16*, 339; Hoppe, D. *Angew. Chem. Int. Ed.* **1974**, *13*, 789.

When the reaction is run with potassium *tert*-butoxide in THF at -5°C , one obtains (after hydrolysis) the normal Knoevenagel product **49**, except that the isocyano group has been hydrated (**16-97**).¹¹⁹⁸ With the same base but with 1,2-dimethoxyethane (DME) as solvent the product is the nitrile **50**.¹¹⁹⁹ When the ketone is treated with **48** and thallium(I) ethoxide in a 4:1 mixture of absolute ethanol and DME at room temperature, the product is a 4-ethoxy-2-oxazoline **51**.¹²⁰⁰ Since **50** can be hydrolyzed¹²⁰¹ to a carboxylic acid¹¹⁹⁸ and **51** to an α -hydroxy aldehyde,¹²⁰⁰ this versatile reaction provides a means for achieving the conversion of RCOR' to $\text{RCHR}'\text{COOH}$, $\text{RCHR}'\text{CN}$, or $\text{RCR}'(\text{OH})\text{CHO}$. The conversions to $\text{RCHR}'\text{COOH}$ and to $\text{RCHR}'\text{CN}$ ¹²⁰² have also been carried out with certain aldehydes ($\text{R}' = \text{H}$).

- Aldehydes and ketones RCOR' react with α -methoxyvinyl lithium, $\text{CH}_2=\text{C}(\text{Li})\text{OMe}$, to give hydroxy enol ethers, $\text{RR}'\text{C}(\text{OH})\text{C}(\text{OMe})=\text{CH}_2$, which are easily hydrolyzed to acyloins, $\text{RR}'\text{C}(\text{OH})\text{COMe}$.¹²⁰³ In this reaction, the $\text{CH}_2=\text{C}(\text{Li})\text{OMe}$ is a synthon for the unavailable $\text{H}_3\text{C}-\overset{\ominus}{\text{C}}=\text{O}$,¹²⁰⁴ and is termed an *acyl anion equivalent*. The reagent also reacts with esters RCOOR' to give $\text{RC}(\text{OH})(\text{COMe}=\text{CH}_2)_2$. A synthon for the $\text{Ph}-\text{C}=\text{O}$ ion is $\text{PhC}(\text{CN})\text{OSiMe}_3$, which adds to aldehydes and ketones RCOR' to give, after hydrolysis, the α -hydroxy ketones, $\text{RR}'\text{C}(\text{OH})\text{C}(\text{OH})\text{COPh}$.¹²⁰⁵
- Lithiated allylic carbamates (**52**) (prepared as shown) react with aldehydes or ketones ($\text{R}^6\text{COR}'$), in a reaction accompanied by an allylic rearrangement, to give (after hydrolysis) γ -hydroxy aldehydes or ketones.¹²⁰⁶ The reaction is called *the homoaldol reaction*, since the product is a homolog of the product of **16-34**. The reaction has been performed enantioselectively.¹²⁰⁷

5. The lithium salt of an active hydrogen compound adds to the lithium salt of the tosylhydrazone of an aldehyde to give product **53**. If X = CN, SPh, or SO₂R, **53** spontaneously loses N₂ and LiX to give the alkene **54**. The entire process is done in one reaction vessel: The active hydrogen compound is mixed with the tosylhydrazone and the mixture is treated with (*i*Pr)₂NLi to form both salts at once.¹²⁰⁸ This process is another alternative to the Wittig reaction for forming double bonds.

OS **I**, 181, 290, 413; **II**, 202; **III**, 39, 165, 317, 320, 377, 385, 399, 416, 425, 456, 479, 513, 586, 591, 597, 715, 783; **IV**, 93, 210, 221, 234, 293, 327, 387, 392, 408, 441, 463, 471, 549, 573, 730, 731, 777; **V**, 130, 381, 572, 585, 627, 833, 1088, 1128; **VI**, 41, 95, 442, 598, 683; **VII**, 50, 108, 142, 276, 381, 386, 456; **VIII**, 258, 265, 309, 353, 391, 420; **X**, 271. 16-39 The Perkin Reaction

α -Carboxyalkylidene-de-oxo-bisubstitution

The condensation of aromatic aldehydes with anhydrides is called the *Perkin reaction*.¹²⁰⁹ When the anhydride has two α hydrogens (as shown), dehydration

¹²⁰⁸Vedejs, E.; Dolphin, J.M.; Stolle, W.T. *J. Am. Chem. Soc.* **1979**, *101*, 249.

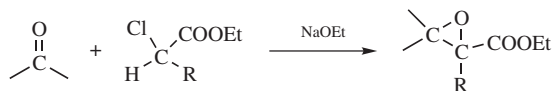

¹²⁰⁹For a review, see Johnson, J.R. *Org. React.* **1942**, *1*, 210.

always occurs; the β -hydroxy acid salt is never isolated. In some cases, anhydrides of the form $(R_2CHCO)_2O$ have been used, and then the hydroxy compound is the product since dehydration cannot take place. The base in the Perkin reaction is nearly always the salt of the acid corresponding to the anhydride. Although the Na and K salts have been most frequently used, higher yields and shorter reaction times have been reported for the Cs salt.¹²¹⁰ Besides aromatic aldehydes, their vinyls $ArCH=CHCHO$ also give the reaction. Otherwise, the reaction is not suitable for aliphatic aldehydes.¹²¹¹

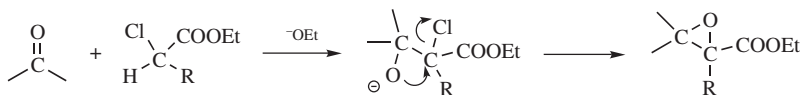

OS I, 398; II, 61, 229; III, 426.

16-40 Darzens Glycidic Ester Condensation

(2 + 1)OC,CC-cyclo- α -Alkoxy carbonylmethylene-addition

Aldehydes and ketones condense with α -halo esters in the presence of bases to give α,β -epoxy esters, called *glycidic esters*. This is called *the Darzens condensation*.¹²¹² The reaction consists of an initial Knoevenagel-type reaction (16-38), followed by an internal S_N^2 reaction (10-9):¹²¹³

Although the intermediate halo alkoxide is generally not isolated,¹²¹⁴ it has been done, not only with α -fluoro esters (since fluorine is such a poor leaving group in nucleophilic substitutions), but also with α -chloro esters.¹²¹⁵ This is only one of several types of evidence that rule out a carbene intermediate.¹²¹⁶ Sodium ethoxide is often used as the base, though other bases, including sodium amide, are sometimes used. Aromatic aldehydes and ketones give good yields, but aliphatic aldehydes react poorly. However, the reaction can be made to give good yields

¹²¹³For discussions of the mechanism of the reaction, and especially of the stereochemistry, see Roux-Schmitt, M.; Seyden-Penne, J.; Wolfe, S. *Tetrahedron* **1972**, 28, 4965; Bansal, R.K.; Sethi, K. *Bull. Chem. Soc. Jpn.* **1980**, 53, 1197.

¹²¹⁴The transition state for this reaction has been examined. See Yliniemelä, A.; Brunow, G.; Flügge, J.; Teleman, O. *J. Org. Chem.* **1996**, 61, 6723.

¹²¹⁵Ballester, M.; Pérez-Blanco, D. *J. Org. Chem.* **1958**, 23, 652; Martynov, V.F.; Titov, M.I. *J. Gen. Chem. USSR* **1963**, 33, 1350; **1964**, 34, 2139; Elkik, E.; Francesch, C. *Bull. Soc. Chim. Fr.* **1973**, 1277, 1281.

¹²¹⁶Another, based on the stereochemistry of the products, is described by Zimmerman, H.E.; Ahramjian, L. *J. Am. Chem. Soc.* **1960**, 82, 5459.

(~80%) with simple aliphatic aldehydes, as well as with aromatic aldehydes and ketones by treatment of the α -halo ester with the base lithium bis(trimethylsilyl) amide, $\text{LiN}(\text{SiMe}_3)_2$, in THF at -78°C (to form the conjugate base of the ester) and addition of the aldehyde or ketone to this solution.¹²¹⁷ If a preformed dianion

of an α -halo carboxylic acid $\text{Cl}-\overset{\ominus}{\text{C}}\text{R}-\text{COO}^\ominus$ is used instead, α,β -epoxy acids are produced directly.¹²¹⁸ The Darzens reaction has also been carried out on α -halo ketones, α -halo nitriles,¹²¹⁹ α -halo sulfoxides¹²²⁰ and sulfones,¹²²¹ α -halo N,N -disubstituted amides,¹²²² α -halo ketimines,¹²²³ and even on allylic¹²²⁴ and benzylic halides. Phase-transfer catalysis has been used.¹²²⁵ Note that the reaction of a β -bromo- α -oxo ester and a Grignard reagent leads to the glycidic ester.¹²²⁶ Acid-catalyzed Darzens reactions have also been reported.¹²²⁷ (see also, 16-46).

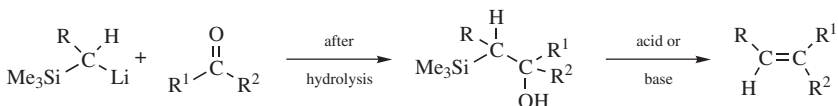

The Darzens reaction has been performed enantioselectively, by coupling optically active α -bromo- β -hydroxy esters with aldehydes.¹²²⁸ Chiral phase-transfer agents have been used to give epoxy ketones with modest enantioselectivity.¹²²⁹ Chiral additives have proven to be effective.¹²³⁰

Glycidic esters can easily be converted to aldehydes (12-40). The reaction has been extended to the formation of analogous aziridines by treatment of an imine with an α -halo ester or an α -halo N,N -disubstituted amide and t -BuOK in the solvent 1,2-dimethoxyethane.¹²³¹ However, yields were not high.

In the *Peterson alkenylation reaction*^{1232, 1233} the lithio (or sometimes magnesio) derivative of a trialkylsilane adds to an aldehyde or ketone to give a β -hydroxysilane, which spontaneously eliminates water, or can be made to do so by treatment with acid or base, to produce an alkene. This reaction is still another alternative to the Wittig reaction (16-44), and is sometimes called the *silyl-Wittig reaction*.¹²³⁴ The R group can also be a COOR group, in which case the product is an α,β -unsaturated ester,¹²³⁵ or an SO₂Ph group, in which case the product is a vinylic sulfone.¹²³⁶ The stereochemistry of the product can often be controlled by whether an acid or a base is used to achieve elimination. The role of Si–O interactions has also been examined.¹²³⁷ Use of a base generally gives syn elimination (Eⁱ mechanism, see p. 1507), while an acid usually results in anti elimination (E2 mechanism, see p. 1478).¹²³⁸ Samarium(II) iodide in HMPA has also been used for elimination of the hydroxy sulfone.¹²³⁹ α -Alkoxy benzotriazolyl sulfones (ROCH₂SO₂Bt, where Bt = benzothiazole, reacts with lithium hexamethyldisilazide and an aldehyde to give a vinyl ether.¹²⁴⁰

When aldehydes or ketones are treated with reagents of the form **55**, the product is an epoxy silane (**16-46**), which can be hydrolyzed to a methyl ketone.¹²⁴¹ For aldehydes, this is a method for converting RCHO to a methyl ketone RCH₂COMe.

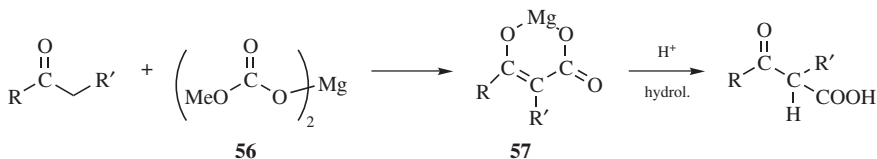

The reagents Me₃SiCHRM (M = Li or Mg) are often prepared from Me₃SiCHRC1¹²⁴² (by **12-38** or **12-39**), but they have also been made by **12-22** and by other procedures.¹²⁴³

A new version of the reaction has been developed, reacting Me₃SiCH₂CO₂Et with an aldehyde and a catalytic amount of CsF in DMSO.¹²⁴⁴ A seleno-amide derivative has been used in a similar manner.¹²⁴⁵

There are no references in *Organic Syntheses*, but see OS VIII, 602, for a related reaction.

16-42 The Addition of Active Hydrogen Compounds to CO₂ and CS₂

α-Acylalkyl-de-methoxy-substitution (Overall reaction)

Ketones of the form RCOCH₃ and RCOCH₂R' can be carboxylated indirectly by treatment with magnesium methyl carbonate **56**.¹²⁴⁶ Because formation of the chelate **57** provides the driving force of the reaction, carboxylation cannot be achieved at a disubstituted α position. The reaction has also been performed on CH₃NO₂ and compounds of the form RCH₂NO₂¹²⁴⁷ and on certain lactones.¹²⁴⁸ Direct carboxylation has been reported in a number of instances. Ketones have

been carboxylated in the α position to give β -keto acids.¹²⁴⁹ The base here was lithium 4-methyl-2,16-di-*tert*-butylphenoxide.

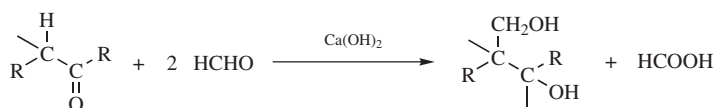

Ketones $\text{RCOCH}_2\text{R}'$ (as well as other active hydrogen compounds) undergo base-catalyzed addition to CS_2 ¹²⁵⁰ to give a dianion intermediate $\text{RCOC}^-\text{R}'\text{CSS}^{2-}$, which can be dialkylated with a halide R^2X to produce α -dithiomethylene ketones, $\text{RCOCR}'=\text{C}(\text{SR}^2)_2$.¹²⁵¹ Compounds of the form $\text{ZCH}_2\text{Z}'$ also react with bases and CS_2 to give analogous dianions.¹²⁵²

Although reactions with $\text{N}=\text{O}$ derivatives do not formally fall into this category of reactions, it is somewhat related. Nitroso compounds react with activated nitriles in the presence of LiBr and microwave irradiation to give a cyano imine, $\text{ArN}=\text{C}(\text{CN})\text{Ar}$.¹²⁵³ This transformation has been called the *Ehrlich-Sachs reaction*.¹²⁵⁴

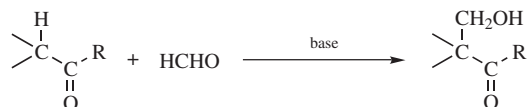

OS VII, 476. See also, OS VIII, 578.

16-43 Tollens' Reaction

O-Hydro-C(β -hydroxyalkyl)-addition

In the *Tollens' reaction* an aldehyde or ketone containing an α hydrogen is treated with formaldehyde in the presence of Ca(OH)_2 or a similar base. The first step is a mixed aldol reaction (**16-34**).

The reaction can be stopped at this point, but more often a second equivalent of formaldehyde is permitted to reduce the newly formed aldol to a 1,3-diol, in a crossed Cannizzaro reaction (**19-81**). If the aldehyde or ketone has several α hydrogens, they can all be replaced. An important use of the reaction is to prepare pentaerythritol from acetaldehyde:

16-44 The Wittig Reaction

Alkylidene-de-oxo-bisubstitution

In the *Wittig reaction* an aldehyde or ketone is treated with a *phosphorus ylid* (also spelled *ylide* and called a *phosphorane*) to give an alkene.¹²⁵⁵ The conversion of a carbonyl compound to an alkene with a phosphorus ylid is called the *Wittig reaction*. Phosphorus ylids are usually prepared by treatment of a phosphonium salt with a base,¹²⁵⁶ and phosphonium salts are usually prepared from a triaryl phosphine and an alkyl halide (**10-31**):

The reaction of triphenylphosphine and an alkyl halides is facilitated by the use of microwave irradiation.¹²⁵⁷ Indeed, the Wittig reaction itself is assisted by microwave irradiation.¹²⁵⁸ Phosphonium salts are also prepared by addition of phosphines to Michael alkenes (like **15-8**) and in other ways. The phosphonium salts are most often converted to the ylids by treatment with a strong base such as

¹²⁵⁵For a general treatise, see Cadogan, J.I.G. *Organophosphorus Reagents in Organic Synthesis*, Academic Press, NY, **1979**. ¹²⁵⁶When phosphonium *fluorides* are used, no base is necessary, as these react directly with the substrate to give the alkene: Schiemenz, G.P.; Becker, J.; Stöckigt, J. *Chem. Ber.* **1970**, *103*, 2077.

¹²⁵⁷Kiddle, J.J. *Tetrahedron Lett.* **2000**, *41*, 1339.

butyllithium, sodium amide,¹²⁵⁹ sodium hydride, or a sodium alkoxide, though weaker bases can be used if the salt is acidic enough. Unusual bases such as 1,5,7-triazabicyclo [4.4.0]dec-5-ene have been used to promote the Wittig reaction.¹²⁶⁰ In some cases, and excess of fluoride ion is sufficient.¹²⁶¹ For $(\text{Ph}_3\text{P}^+)_2\text{CH}_2$, sodium carbonate is a strong enough base.¹²⁶² When the base used does not contain lithium, the ylid is said to be prepared under “salt-free” conditions¹²⁶³ because the lithium halide (where the halide counterion comes from the phosphonium salt) is absent.

When the phosphorus ylid reacts with the aldehyde or ketone to form an alkene, a phosphine oxide is also formed. When triphenylphosphine is used to give $\text{Ph}_3\text{P}=\text{CRR}'$, for example, the by-product is triphenylphosphine oxide, Ph_3PO , which is sometimes difficult to separate from the other reaction products. Ylids are usually prepared from triphenylphosphine, but other triarylphosphines,¹²⁶⁴ trialkylphosphines,¹²⁶⁵ and triphenylarsine¹²⁶⁶ have also been used. Tellurium ylids have been prepared *in situ* from α -halo esters and $\text{BrTeBu}_2\text{OTeBu}_2\text{Br}$ and react with aldehydes to give conjugated esters.¹²⁶⁷ Polymer-bound aryldiphenylphosphino compounds¹²⁶⁸ have been used in reactions with alkyl halides to complete a Wittig reaction. Phosphines that have an α -hydrogen should be avoided, so that reaction with the chosen alkyl halide will lead to a phosphonium salt (**58**) with the α -proton at the desired position. This limitation is essential if a specific ylid is to be formed from the alkyl halide precursor. The Wittig reaction has been carried out with polymer-supported ylids.¹²⁶⁹ It has also been done on silica gel.¹²⁷⁰

If we view the Wittig reaction from an alkyl halide starting material (alkyl halide phosphonium salt \rightarrow phosphorus ylid \rightarrow alkene), the halogen-bearing carbon of an alkyl halide must contain at least one hydrogen as in **59** (for deprotonation at the phosphonium salt stage).

¹²⁶⁶An arsenic ylid has been used in a catalytic version of the Wittig reaction; that is, the R_3AsO product is constantly regenerated to produce more arsenic ylid: Shi, L.; Wang, W.; Wang, Y.; Huang, Y. *J. Org. Chem.* **1989**, *54*, 2027; Huang, Z.-Z.; Huang, X.; Huang, Y.-Z. *Tetrahedron Lett.* **1995**, *36*, 425.

¹²⁶⁷Huang, Z.-Z.; Tang, Y. *J. Org. Chem.* **2002**, *67*, 5320.

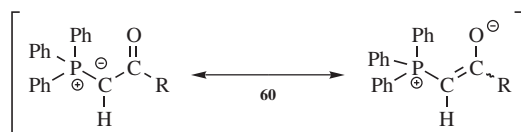

¹²⁶⁸Betancort, J.M.; Barbas III, C.F. *Org. Lett.* **2001**, *3*, 3737.

¹²⁶⁹Bernard, M.; Ford, W.T.; Nelson, E.C. *J. Org. Chem.* **1983**, *48*, 3164.

¹²⁷⁰Patil, V.J.; Mävers, U. *Tetrahedron Lett.* **1996**, *37*, 1281.

The reaction is very general.¹²⁷¹ The aldehyde or ketone may be aliphatic, alicyclic, or aromatic (including diaryl ketones). Wittig reactions in which the ylid and/or the carbonyl substrate contain double or triple bonds; it may contain various functional groups, such as OH, OR, NR₂, aromatic nitro or halo, acetal, amide,¹²⁷² or even ester groups.¹²⁷³ Note, however, that a Wittig reaction has been reported in which the carbonyl group of an ester was converted to a vinyl ether.¹²⁷⁴ An important advantage of the Wittig reaction is that the *position* of the new double bond is always certain, in contrast to the result in most of the base-catalyzed condensations (16-34-16-43). Ylids have been shown to react with lactones, however, to form ω-alkenyl alcohols.¹²⁷⁵ β-Lactams have also been converted to alkenyl-azetidine derivatives using phosphorus ylids.¹²⁷⁶ Double or triple bonds *conjugated* with the carbonyl also do not interfere, the attack being at the C=O carbon. The carbonyl partner can be generated *in situ*, in the presence of an ylid; the reaction of an alcohol with a mixture of an oxidizing agent and an ylid generates an alkene. Oxidizing agents used in this manner include BaMnO₄,¹²⁷⁷ MnO₂,¹²⁷⁸ and PhI(OAc)₂.¹²⁷⁹ Polyhalomethanes, such as CBr₃F, react with triphenylphosphine in the presence of diethylzinc and an aldehyde or ketone to give the *gem*-dihaloalkene, RCH(R')=CF(Br).¹²⁸⁰

The phosphorus ylid may also contain double or triple bonds and certain functional groups. Simple ylids (R, R' = hydrogen or alkyl) are highly reactive, reacting with oxygen, water, hydrohalic acids, and alcohols, as well as carbonyl compounds and carboxylic esters, so the reaction must be run under conditions where these materials are absent. When an electron-withdrawing group, for example, COR, CN, COOR, CHO, is present in the α position, the ylids are much more stable, because the charge on the carbon is delocalized by resonance as in 60.

¹²⁷¹For a discussion of a cooperative ortho effect, see Dunne, E.C.; Coyne, É.J.; Crowley, P.B.; Gilheany, D.G. *Tetrahedron Lett.* **2002**, *43*, 2449.

¹²⁷²Smith, M.B.; Kwon, T.W. *Synth. Commun.* **1992**, *22*, 2865. For the reaction of an acyl imidazole ylid, see Matsunaga, S.; Kinoshita, T.; Okada, S.; Harada, S.; Shibasaki, M. *J. Am. Chem. Soc.* **2004**, *126*, 7559.

¹²⁷³For an example, see Harcken, C.; Martin, S.F. *Org. Lett.* **2001**, *3*, 3591; Yu, X.; Huang, X. *Synlett* **2002**, 1895. Although phosphorus ylids also react with esters, that reaction is too slow to interfere: Greenwald, R.; Chaykovsky, M.; Corey, E.J. *J. Org. Chem.* **1963**, *28*, 1128.

¹²⁷⁹Zhang, P.-F.; Chen, Z.-C. *Synth. Commun.* **2001**, *31*, 1619.

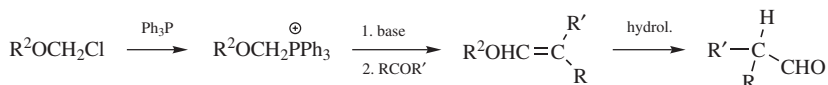

¹²⁸⁰Lei, X.; Dutheuil, G.; Pannecoucke, X.; Quirion, J.-C. *Org. Lett.* **2004**, *6*, 2101.

Such ylids react readily with aldehydes, but slowly or not at all with ketones.¹²⁸¹ In extreme cases (e.g., **61**), the

61

ylid does not react with ketones *or* aldehydes. Besides these groups, the ylid may contain one or two α halogens¹²⁸² or an α OR or OAr group. In the latter case, the product is an enol ether, which can be hydrolyzed

(**10-6**) to an aldehyde,¹²⁸³ so that this reaction is a means of achieving the conversion $\text{RCOR}' \rightarrow \text{RR}'\text{CHCHO}$.¹²⁸⁴ However, the ylid may not contain an α nitro group. If the phosphonium salt contains a potential leaving group, such as Br or OMe, in the β position, treatment with a base gives elimination, instead of the ylid:

However, a β COO^- group may be present, and the product is a β,γ -unsaturated acid:¹²⁸⁵ This is the only convenient way to make these compounds, since elimination by any other route gives the thermodynamically more stable α,β -unsaturated isomers. This is an illustration of the utility of the Wittig method for the specific location of a double bond. Another illustration is the conversion of cyclohexanones to alkenes containing exocyclic double bonds, for example,¹²⁸⁶

¹²⁸¹For successful reactions of stabilized ylids with ketones, under high pressure, see Isaacs, N.S.; El-Din, G.N. *Tetrahedron Lett.* **1987**, 28, 2191. See also, Dauben, W.G.; Takasugi, J.J. *Tetrahedron Lett.* **1987**, 28, 4377.

¹²⁸⁶Wittig, G.; Schöllkopf, U. *Chem. Ber.* **1954**, 87, 1318.

Still another example is the easy formation of anti-Bredt bicycloalkenones¹²⁸⁷ (see p. 229). As indicated above, α, α' -dihalophosphoranes can be used to prepare 1,1-dihaloalkenes. Another way to prepare such compounds¹²⁸⁸ is to treat the carbonyl compound with a mixture of CX_4 ($X = Cl, Br, \text{ or } I$) and triphenylphosphine, either with or without the addition of zinc dust (which allows less Ph_3P to be used).¹²⁸⁹ Aryl aldehydes react with these dihalophosphoranes to give aryl alkynes after treatment of the initially formed vinyl halide with potassium *tert*-butoxide.¹²⁹⁰ Formamides have been converted to ynamines by reaction with a mixture of PPh_3/CCl_4 followed by *n*-butyllithium.¹²⁹¹ The carbonyl compound can be generated *in situ*, in the presence of the phosphorane. A cyclopropylcarbonyl alcohol was converted to a β -cyclopropyl- α, β -unsaturated ester by reaction with MnO_2 in the presence of $Ph_3P=CHCO_2Me$.¹²⁹²

The mechanism¹²⁹³ of the key step of the Wittig reaction is as follows:¹²⁹⁴

The energetics of ylid formation and their reaction in solution has been studied.¹²⁹⁵ For many years it was assumed that a diionic compound, called a *betaine*, is an intermediate on the pathway from the starting compounds

¹²⁸⁷Bestmann, H.J.; Schade, G. *Tetrahedron Lett.* **1982**, 23, 3543.

¹²⁸⁸For a list of references to the preparation of haloalkenes by Wittig reactions, with references, see Larock, R.C. *Comprehensive Organic Transformations*, 2nd ed., Wiley-VCH, NY, **1999**, pp. 725–727.

¹²⁸⁹See, for example, Rabinowitz, R.; Marcus, R. *J. Am. Chem. Soc.* **1962**, 84, 1312; Ramirez, F.; Desai, N.B.; McKelvie, N. *J. Am. Chem. Soc.* **1962**, 84, 1745; Corey, E.J.; Fuchs, P.L. *Tetrahedron Lett.* **1972**, 3769; Posner, G.H.; Loomis, G.L.; Sawaya, H.S. *Tetrahedron Lett.* **1975**, 1373; Suda, M.; Fukushima, A. *Tetrahedron Lett.* **1981**, 22, 759; Gaviña, F.; Luis, S.V.; Ferrer, P.; Costero, A.M.; Marco, J.A. *J. ¹²⁹³For a review of the mechanism, see Cockerill, A.F.; Harrison, R.G., in Patai, S. *The Chemistry of Functional Groups: Supplement A*, pt. 1, Wiley, NY, **1977**, pp. 232–240. For a thorough discussion, see Vedejs, E.; Marth, C.F. *J. Am. Chem. Soc.* **1988**, 110, 3948.

¹²⁹⁴It has been contended that another mechanism, involving single electron transfer, may be taking place in some cases: Olah, G.A.; Krishnamurthy, V.V. *J. Am. Chem. Soc.* **1982**, 104, 3987; Yamataka, H.; Nagareda, K.; Hanafusa, T.; Nagase, S. *Tetrahedron Lett.* **1989**, 30, 7187. A diradical mechanism has also been proposed for certain cases: Ward, Jr., W.J.; McEwen, W.E. *J. Org. Chem.* **1990**, 55, 493.

¹²⁹⁵Arnett, E.M.; Wernett, P.C. *J. Org. Chem.* **1993**, 58, 301.

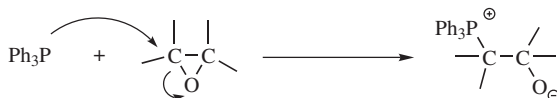

to the oxaphosphetane, and in fact it may be so, but there is little evidence for it.¹²⁹⁶

Betaine

“Betaine” precipitates have been isolated in certain Wittig reactions,¹²⁹⁷ but these are betaine–lithium halide adducts, and might just as well have been formed from the oxaphosphetane as from a true betaine.¹²⁹⁸ However, there is one report of an observed betaine lithium salt during the course of a Wittig reaction.¹²⁹⁹ An X-ray structure was determined for a gauche betaine from a thio-Wittig reaction.¹³⁰⁰ In contrast, there is much evidence for the presence of the oxaphosphetane intermediates, at least with unstable ylids. For example, ³¹P NMR spectra taken of the reaction mixtures at low temperatures¹³⁰¹ are compatible with an oxaphosphetane structure that persists for some time but not with a tetra-coordinated phosphorus species. Since a betaine, an ylid, and a phosphine oxide all have tetracoordinated phosphorus, these species could not be causing the spectra, leading to the conclusion that an oxaphosphetane intermediate is present in the solution. In certain cases oxaphosphetanes have been isolated.¹³⁰² It has even been possible to detect cis and trans isomers of the intermediate oxaphosphetanes by NMR spectroscopy.¹³⁰³ According to this mechanism, an optically active phosphonium salt RR'R²P⁺CHR² should retain its configuration all the way through the reaction, and it should be preserved in the phosphine oxide RR'R²PO. This has been shown to be the case.¹³⁰⁴

The proposed betaine intermediates can be formed, in a completely different manner, by nucleophilic substitution by a phosphine on an epoxide (**10-35**):

Betaines formed in this way can then be converted to the alkene, and this is one reason why betaine intermediates were long accepted in the Wittig reaction.

The Wittig reaction has also been carried out with phosphorus ylids other than phosphoranes, the most important being prepared from phosphonates, such as **62**.¹³⁰⁵

This method, sometimes called the *Horner–Emmons*, *Wadsworth–Emmons*, or *Wittig–Horner reaction*,¹³⁰⁶ has several advantages over the use of phosphoranes, including selectivity.¹³⁰⁷ These ylids are more reactive than the corresponding phosphoranes, and when R¹ or R² is an electron-withdrawing group, these compounds often react with ketones that are inert to phosphoranes. High pressure has been used to facilitate this reaction.¹³⁰⁸ In addition, the phosphorus product is a phosphate ester and hence soluble in water, unlike Ph₃PO, which makes it easy to separate it from the alkene product. Phosphonates are also cheaper than phosphonium salts and can easily be prepared by the *Arbuzov reaction*.¹³⁰⁹

Phosphonates have also been prepared from alcohols and (ArO)₂P(=O)Cl, NEt₃ and a TiCl₄ catalyst.¹³¹⁰ The reaction of (RO)₂P(=O)H and aryl iodides with a CuI catalyst leads to aryl phosphonates.¹³¹¹ Polymer-bound phosphonate esters have been used for olefination.¹³¹² Dienes are produced when allylic phosphonate esters react with aldehydes.¹³¹³

Stereoselective alkenylation reactions have been achieved using chiral additives¹³¹⁴ or auxiliaries.¹³¹⁵ Ylids formed from phosphine oxides,

phosphonic acid bisamides, $(\text{R}_2\text{N})_2\text{POCHRR}'$,¹³¹⁶ and alkyl phosphonothionates, $(\text{MeO})_2\text{PSCHRR}'$,¹³¹⁷ share some of these advantages. Reagents, such as $\text{Ph}_2\text{POCH}_2\text{NR}'_2$, react with aldehydes or ketones (R_2COR^3) to give good yields of enamines ($\text{R}^2\text{R}^3\text{C}=\text{CHNR}$).¹³¹⁸ (*Z*)-Selective reagents are also known,¹³¹⁹ including the use of a di(2,2,2-trifluoroethoxy)phosphonate with KHMDS and 18-crown-6.¹³²⁰ An interesting intramolecular version of the Horner–Emmons reaction leads to alkynes.¹³²¹ The reaction of a functionalized aldehyde ($\text{R}-\text{CHO}$) with $(\text{MeO})_2\text{POCHN}_2$, leads to the alkyne ($\text{R}-\text{C}\equiv\text{CH}$).¹³²²

Some Wittig reactions give the (*Z*)-alkene; some the (*E*), and others give mixtures, and the question of which factors determine the stereoselectivity has been much studied.¹³²³ It is generally found that ylids containing stabilizing groups or formed from trialkylphosphines give (*E*)-alkenes. However, ylids formed from triarylphosphines and not containing stabilizing groups often give (*Z*) or a mixture of (*Z*) and (*E*)-alkenes.¹³²⁴ One explanation for this¹³²³ is that the reaction of the ylid with the carbonyl compound is a [2 + 2]-cycloaddition, which in order to be concerted must adopt the $[\pi_{2s} + \pi_{2a}]$ pathway. As we have seen earlier (p. 1225), this pathway leads to the formation of the more sterically crowded product, in this case the *Z* alkene. If this explanation is correct, it is not easy to explain the predominant formation of (*E*)

products from stable ylids, but (*E*) compounds are of course generally thermodynamically more stable than the (*Z*) isomers, and the stereochemistry seems to depend on many factors.

The (*E/Z*) ratio of the product can often be changed by a change in solvent or by the addition of salts.¹³²⁵ Another way of controlling the stereochemistry of the product is by use of the aforementioned phosphonic acid bisamides. In this case, the betaine (**63**) does form and when treated with water gives the β-hydroxyphosphonic acid bisamides **64**, which can be crystallized and then cleaved to R¹R²C=CR³R⁴ by refluxing in benzene or toluene in the presence of silica gel.¹³¹⁶ **64** are generally formed as mixtures of diastereomers, and these mixtures can be separated by recrystallization. Cleavage of the two diastereomers gives the two isomeric alkenes. Optically active phosphonic acid bisamides have been used to give optically active alkenes.¹³²⁶ Another method of controlling the stereochemistry of the alkene [to obtain either the (*Z*) or (*E*) isomer] starting with a phosphine oxide (Ph₂POCH₂R), has been reported.¹³²⁷

In reactions where the betaine–lithium halide intermediate is present, it is possible to extend the chain further if a hydrogen is present α to the phosphorus. For example, reaction of ethylidnetriphenylphosphorane with heptanal at −78°C gave **65**, which with butyllithium gave the ylid **66**. Treatment of this with an aldehyde R'CHO gave the intermediate **67**, which after workup gave **68**.¹³²⁸ This reaction gives the unsaturated alcohols **68** stereoselectively. **66** also reacts with other electrophiles. For example, treatment of **66** with *n*-chlorosuccinimide or PhICl₂ gives the vinylic chloride RCH=CMeCl stereoselectively: NCS giving the *cis* and PhICl₂

the trans isomer.¹³²⁹ The use of Br₂ and FClO₃ (see **12-4** for the explosive nature of this reagent) gives the corresponding bromides and fluorides, respectively.¹³³⁰ Reactions of **66** with electrophiles have been called *scoopy* reactions (α substitution plus carbonyl alkenylation via β -oxido phosphorus ylids).¹³³¹

The reaction of a phosphonate ester, DBU, NaI, and HMPA with an aldehyde leads to a conjugated ester with excellent (*Z*)-selectivity.¹³³² A (*Z*)-selective reaction was reported using a trifluoroethyl phosphonate in a reaction with an aldehyde and potassium *tert*-butoxide.¹³³³

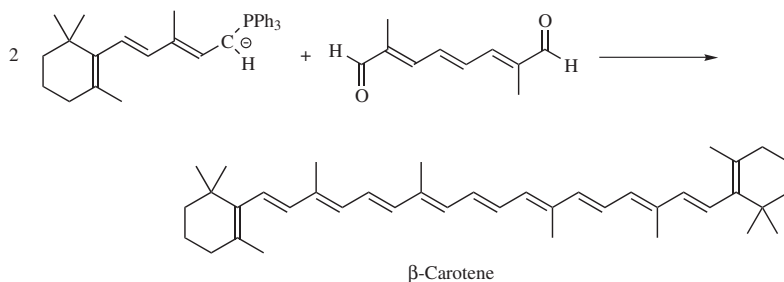

The Wittig reaction has been carried out intramolecularly, to prepare rings containing from 5 to 16 carbons,¹³³⁴ both by single ring closure

and double ring closure.¹³³⁵

The Wittig reaction has proved very useful in the synthesis of natural products, some of which are quite difficult to prepare in other ways.¹³³⁶ One example out of many is the synthesis of β -carotene.¹³³⁷

16-45 Tebbe, Petasis and Alternative Alkenylations

Methylene-de-oxo-bisubstitution

A useful alternative to phosphorus ylids are the titanium reagents, such as, **71**, prepared from dicyclopentadienyltitanium dichloride and trimethylaluminum.¹³⁴⁷ Treatment of a carbonyl compound with the titanium cyclopentadienide complex **71** (*Tebbe's reagent*) in toluene–THF containing a small amount of pyridine¹³⁴⁸ leads to the alkene. Dimethyltitanocene (Me_2TiCp_2), called the *Petasis reagent*, is a convenient and highly useful alternative to **71**.¹³⁴⁹ The mechanism of Petasis olefination has been examined.¹³⁵⁰ Tebbe's reagent and the Petasis reagent give good results with ketones.¹³⁵¹ An important feature of these new reagents is that

carboxylic esters and lactones¹³⁵² can be converted in good yields to the corresponding enol ethers. The enol ether can be hydrolyzed to a ketone (**10-6**), so this is also an indirect method for making the conversion $\text{RCOOR}' \rightarrow \text{RCOCH}_3$ (see also, **16-82**). Conjugated esters are converted to alkoxy-dienes with this reagent.¹³⁵³ Lactams, including β -lactams, are converted with alkylidene cycloamines (alkylidene azetidines from β -lactams, which are easily hydrolyzed to β -amino ketones).¹³⁵⁴

Besides stability and ease of preparation, another advantage of the Petasis reagent is that structural analogs can be prepared, including $\text{Cp}_2\text{Ti}(\text{C}_3\text{H}_5)_2$ ¹³⁵⁵ ($\text{C}_3\text{H}_5 = \text{cyclopropyl}$), $\text{CpTi}(\text{CH}_2\text{SiMe}_3)_3$,¹³⁵⁶ and $\text{Cp}_2\text{TiMe}(\text{CH}=\text{CH}_2)$.¹³⁵⁷ In another variation, 2 equivalents of $\text{Cp}_2\text{Ti}[\text{P}(\text{OEt})_3]_2$ reacted with a ketone in the presence of 1,1-diphenylthiocyclobutane to give the alkenylcyclobutane derivative.¹³⁵⁸ An alternative titanium reagent was prepared using TiCl_4 , magnesium metal and dichloromethane, reacting with both ketones¹³⁵⁹ and esters¹³⁶⁰ to give alkenes or vinyl ethers, respectively. Alkenes are generated from ketones and alkyl iodides in the presence of a catalytic amount of $\text{Cp}_2\text{Ti}[\text{POEt}_3]_2$.¹³⁶¹

α,α -Dibromosulfones ($\text{ArSO}_2\text{SHBr}_2$) react with ketones in the presence of Sm/SmI_2 and a CrCl_3 catalyst gives to corresponding vinyl sulfone.¹³⁶² Imides are converted to alkylidene lactams when treated with an alkyl halide, 2.5 equivalents of SmI_2 and a NiI_2 catalyst.¹³⁶³

Carboxylic esters undergo the conversion $\text{C}=\text{O} \rightarrow \text{C}=\text{CHR}$ ($\text{R} = \text{primary or secondary alkyl}$) when treated with RCHBr_2 , Zn ,¹³⁶⁴ and TiCl_4 in the presence of N,N,N',N' -tetramethylethylenediamine.¹³⁶⁵ Metal carbene complexes¹³⁶⁶ $\text{R}_2\text{C} = \text{ML}_n$ ($\text{L} = \text{ligand}$), where M is a transition metal, such as Zr , W , or Ta , have also been

For the reaction with $\text{CH}_2(\text{ZnI})_2$ with TiCl_2 , see Matsubara, S.; Ukai, K.; Mizuno, T.; Utimoto, K. *Chem. Lett.* **1999**, 825. This procedure is also successful for silyl esters, to give silyl enol ethers: Takai, K.; Kataoka, Y.; Okazoe, T.; Utimoto, K. *Tetrahedron Lett.* **1988**, 29, 1065.

¹³⁶⁶For a review of the synthesis of such complexes, see Aguero, A.; Osborn, J.A. *New J. Chem.* **1988**, 12, 111.

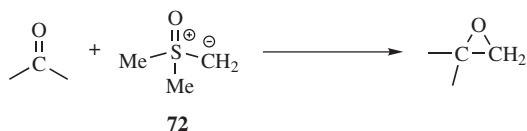

used to convert the C=O of carboxylic esters and lactones to CR₂.¹³⁶⁷ It is likely that the complex Cp₂Ti = CH₂ is an intermediate in the reaction with Tebbe's reagent.

There are a few other methods for converting ketones or aldehydes to alkenes. When a ketone is treated with CH₃CHBr₂/Sm/SmI₂, with a catalytic amount of CrCl₃, for example, the alkene is formed.¹³⁶⁸ α-Halo esters also react with CrCl₃ in the presence of a ketone to give vinyl halides.¹³⁶⁹ In another reaction, an aldehyde reacted with EtCHBr(OAc) in the presence of Zn/CrCl₃ to give the alkene.¹³⁷⁰ α-Diazo esters react with ketones in the presence of an iron catalyst to give the corresponding alkene.¹³⁷¹ α-Diazo silylalkanes react similarly in the presence of a rhodium catalyst.¹³⁷² Benzylic alcohols also react with α-diazo silylalkanes in the presence of a rhodium catalyst, to give alkenes after pretreatment with oxygen and a palladium catalyst.¹³⁷³ The react of aryl aldehydes and MeC(CO₂Et)₃, with a catalytic amount of phenol leads to the corresponding conjugated ethyl ester (ArCH=CHCO₂Et).¹³⁷⁴

methylid (73).¹³⁷⁶ For most purposes, 72 is the

reagent of choice, because 73 is much less stable and ordinarily must be used as soon as it is formed, while 72 can be stored several days at room temperature. When diastereomeric epoxides can be formed, 73 usually attacks from the more hindered and 72 from the less-hindered side. Thus, 4-*tert*-butylcyclohexanone, treated with 72 gave exclusively 75 while 73 gave mostly 74.¹³⁷⁷ Another difference in behavior between the

two reagents is that with α,β -unsaturated ketones, 72 gives only cyclopropanes (reaction 15-64), while 73 gives oxirane formation. Other sulfur ylids have been used in an analogous manner, to transfer CHR or CR₂.¹³⁷⁸ High yields have been achieved by the use of sulfonium ylids anchored to insoluble polymers under phase-transfer conditions.¹³⁷⁹ A solvent-free version of this reaction has been developed using powdered K *tert*-butoxide and Me₃S⁺I⁻.¹³⁸⁰ Note that treatment of epoxides with 2 equivalents of Me₂S=CH₂ leads to allylic alcohols.¹³⁸¹ Other sulfur ylids convert aldehydes to epoxides, including the one generated *in situ* from RR'S⁺CH₂COO⁻.¹³⁸² Chiral sulfur ylids¹³⁸³ have been prepared, giving

the epoxide with good asymmetric induction.¹³⁸⁴ Chiral selenium ylids have been used in a similar manner.¹³⁸⁵

The generally accepted mechanism for the reaction between sulfur ylids and aldehydes or ketone is formation of **76**, with displacement of the Me₂S leaving group by the alkoxide.¹³⁸⁶ This mechanism is similar to that of the reaction of sulfur ylids with C=C double bonds (**15-64**).¹³⁸⁷ The stereochemical difference in the behavior of **72** and **73** has been attributed to formation of the betaine **76** being reversible for **72**, but not for the less stable **73**, so that the more-hindered product is the result of kinetic control and the less-hindered of thermodynamic control.¹³⁸⁸

Phosphorus ylids do not give this reaction, but give **16-44** instead.

Aldehydes and ketones can also be converted to epoxides by treatment with a diazoalkane,¹³⁸⁹ most commonly diazomethane, but an important side reaction is the formation of an aldehyde or ketone with one more carbon than the starting compound (reaction **18-9**). The reaction can be carried out with many aldehydes, ketones, and quinones, usually with a rhodium catalyst.¹³⁹⁰ A mechanism that accounts for both products is

Compound **77** or nitrogen-containing derivatives of it have sometimes been isolated.

An alternative route to epoxides from ketones uses α -chloro sulfones and potassium *tert*-butoxide to give α,β -epoxy sulfones.¹³⁹¹ A similar reaction was reported

using KOH and 10% of a chiral phase-transfer agent, giving moderate enantioselectivity in the epoxy sulfone product.¹³⁹²

Dihalocarbenes and carbenoids, which readily add to C=C bonds (**15-64**), do not generally add to the C=O bonds of ordinary aldehydes and ketones.¹³⁹³ See also, **16-91**.

OS V, 358, 755.

16-47 The Formation of Aziridines from Imines

(1 + 2)NC,CC-cyclo-Methylene-addition

Just as sulfur ylids react with the carbonyl of an aldehyde or ketone to give an epoxide, tellurium ylids react with imines to give an aziridine. The reaction of an allylic tellurium salt, $\text{RCH}=\text{CHCH}_2\text{Te}^+\text{Bu}_2 \text{Br}^-$, with lithium hexamethyldisilazide in HMPA/toluene leads to the tellurium ylid via deprotonation. In the presence of an imine, the ylid add to the imine and subsequent displacement of Bu_2Te generates an aziridine with a pendant vinyl group.¹³⁹⁴

16-48 The Formation of Episulfides and Episulfones¹³⁹⁵

Epoxides can be converted directly to episulfides by treatment with NH_4SCN and ceric ammonium nitrate.¹³⁹⁶ Diazoalkanes, treated with sulfur, give episulfides.¹³⁹⁷ It is likely that $\text{R}_2\text{C}=\text{S}$ is an intermediate, which is attacked by another molecule of diazoalkane, in a process similar to that shown in **16-46**. Thioketones *do* react with diazoalkanes to give episulfides.¹³⁹⁸ Thioketones have also been converted to episulfides with sulfur ylids.¹³⁷⁷ Carbenes, such as the dichlorocarbene from CHCl_3 and base, react with thioketones to give an

α,α -dichloro episulfide.¹³⁹⁹

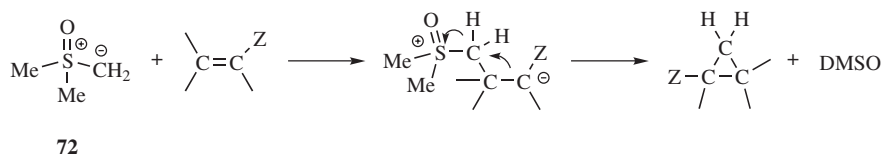

Alkanesulfonyl chlorides, when treated with diazomethane in the presence of a base (usually a tertiary amine), give episulfones (**79**).¹⁴⁰⁰ The base removes HCl from the sulfonyl halide to produce the highly reactive sulfene (**78**) (**17-14**), which then adds CH_2 . The episulfone can then be heated to give off SO_2 (**17-20**), making the entire process a method for achieving the conversion $\text{RCH}_2\text{SO}_2\text{Cl} \rightarrow \text{RCH}=\text{CH}_2$.¹⁴⁰¹

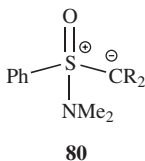

OS V, 231, 877.

16-49 Cyclopropanation of Conjugated Carbonyl Compounds

Double-bond compounds that undergo the Michael reaction (**15-24**) can be converted to cyclopropane derivatives with sulfur ylids.¹⁴⁰² Among the most common of these is dimethylloxosulfonium methylid

72,¹⁴⁰³ which is widely used to transfer CH_2 to activated double bonds, but other sulfur ylids

have also been used. A combination of DMSO and KOH in an ionic liquid converts conjugated ketones to α,β -cyclopropyl ketones.¹⁴⁰⁴ Both CHR and CR₂ can be added in a similar manner with certain nitrogen-containing compounds. For example, ylids,¹⁴⁰⁵ such as **80**, add various groups to activated double bonds.¹⁴⁰⁶ Sulfur ylids react with allylic alcohols in the presence of MnO₂ and molecular sieve 4 Å to give the cyclopropyl aldehyde.¹⁴⁰⁷ Similar reactions have been performed with phosphorus ylids,¹⁴⁰⁸ with pyridinium ylids,¹⁴⁰⁹ and with the compounds (PhS)₃CLi and Me₃Si(PhS)₂CLi.¹⁴¹⁰ The reactions with ylids such as these involve of course nucleophilic acyl addition.

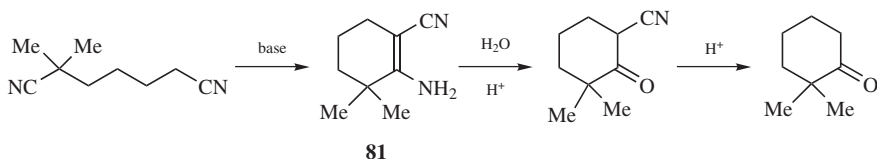

Other reagents can be used to convert an aldehyde or ketone to a cyclopropane derivative. Conjugated ketones react with Cp₂Zr(CH₂—CH₂) and PMe₃ to give a vinyl cyclopropane derivative after treatment with aqueous sulfuric acid.¹⁴¹¹

16-50 The Thorpe Reaction

N-Hydro-C-(α -cyanoalkyl)-addition

In the *Thorpe reaction*, the α carbon of one nitrile molecule is added to the CN carbon of another, so this reaction is analogous to the aldol reaction (16-34). The C=NH bond is, of course, hydrolyzable (16-2), so β -keto nitriles can be prepared in this manner. The Thorpe reaction can be done intramolecularly, in which case it is

called the *Thorpe-Ziegler reaction*.¹⁴¹² This is a useful method for closing large rings. Yields are high for five- to eight-membered rings, fall off to about zero for rings of nine to thirteen members, but are high again for fourteen-membered and larger rings, if high-dilution techniques are employed. The product in the Thorpe-Ziegler reaction is not the imine, but the tautomeric enamine, for example, **81**; if desired this can be hydrolyzed to an α -cyano ketone (**16-2**), which can in turn be hydrolyzed and decarboxylated (**16-4**, **12-40**). Other active-hydrogen compounds can also be added to nitriles.¹⁴¹³

OS VI, 932.

H. Other Carbon or Silicon Nucleophiles

16-51 Addition of Silanes

O-Hydro-C-alkyl-addition

Allylic silanes react with aldehydes, in the presence of Lewis acids, to give a homoallylic alcohol.¹⁴¹⁴ In the case of benzylic silanes, this addition reaction has been induced with $\text{Mg}(\text{ClO}_4)_2$ under photochemical conditions.¹⁴¹⁵ Cyclopropyl-carbinyl silanes add to acetals in the presence of TMSOTf to give a homoallylic alcohol.¹⁴¹⁶ Allyltrichlorosilane adds an allyl group to an aldehyde in the presence of a cyclic urea and AgOTf .¹⁴¹⁷ The addition of chiral additives leads to the alcohol with good asymmetric induction.¹⁴¹⁸ In a related reaction, allylic silanes react with acyl halides to produce the corresponding carbonyl derivative. The reaction of phenyl chloroformate, allyltrimethylsilane and AlCl_3 , for example, gave phenyl but-3-enoate.¹⁴¹⁹

Allylic silanes also add to imines, in the presence of TiCl_4 , to give amines.¹⁴²⁰

16-52 The Formation of Cyanohydrins

O-Hydro-*C*-cyano-addition

The addition of HCN to aldehydes or ketones produces cyanohydrins.¹⁴²¹ This is an equilibrium reaction, and for aldehydes and aliphatic ketones the equilibrium lies to the right; therefore the reaction is quite feasible, except with sterically hindered ketones such as diisopropyl ketone. However, ketones ArCOR give poor yields, and the reaction cannot be carried out with ArCOAr since the equilibrium lies too far to the left. With aromatic aldehydes the benzoin condensation (16-55) competes. With α,β -unsaturated aldehydes and ketones, 1,4-addition competes (15-38). The reaction has been carried out enantioselectively: optically active cyanohydrins were prepared with the aid of optically active catalysts.¹⁴²² Hydrogen cyanide adds to aldehydes in the presence of a lyase to give the cyanohydrin with good enantioselectivity.¹⁴²³ Cyanohydrins have been formed using a lyase in an ionic liquid.¹⁴²⁴

Ketones of low reactivity, such as ArCOR, can be converted to cyanohydrins by treatment with diethylaluminum cyanide (Et₂AlCN) (see OS VI, 307) or, indirectly, with cyanotrimethylsilane (Me₃SiCN)¹⁴²⁵ in the presence of a Lewis acid or base,¹⁴²⁶

Ketones can be converted to cyanohydrin *O*-carbonates, $R_2C(CN)OCO_2R'$, by reaction with EtO_2C-CN . In the presence of a Cinchona alkaloid, the product is formed with good enantioselectivity.¹⁴⁴³ Potassium cyanide and acetic anhydride reacts with an aldehyde in the presence of a chiral titanium catalyst to give an α -acetoxy nitrile.¹⁴⁴⁴

Rather than direct reaction with an aldehyde or ketone, the bisulfite addition product is often treated with cyanide. The addition is nucleophilic and the actual nucleophile is ^-CN , so the reaction rate is increased by the addition of base.¹⁴⁴⁵ This was demonstrated by Lapworth in 1903, and consequently this was one of the first organic mechanisms to be known.¹⁴⁴⁶ This method is especially useful for aromatic aldehydes, since it avoids competition from the benzoin condensation. If desired, it is possible to hydrolyze the cyanohydrin *in situ* to the corresponding α -hydroxy acid. This reaction is important in the *Kiliani-Fischer* method of extending the carbon chain of a sugar.

A particularly useful variation of this reaction uses cyanide rather than HCN. α -Amino nitriles¹⁴⁴⁷ can be prepared in one step by the treatment of an aldehyde or ketone with NaCN and NH_4Cl . This is called the *Strecker synthesis*;¹⁴⁴⁸ and it is a special case of the Mannich reaction (16-19). Since the CN is easily hydrolyzed to the acid, this is a convenient method for the preparation of α -amino acids. The reaction has also been carried out with $NH_3 + HCN$ and with NH_4CN . Salts of primary and secondary amines can be used instead of NH_4^+ to obtain *N*-substituted and *N,N*-disubstituted α -amino nitriles. Unlike 16-52, the Strecker synthesis is useful for aromatic as well as aliphatic ketones. As in 16-52, the Me_3SiCN method has been used; 76 is converted to the product with ammonia or an amine.¹⁴⁴⁹ The effect of pressure on the Strecker synthesis has been studied.¹⁴⁵⁰

16-53 The Addition of HCN to C=N and C≡N Bonds

N-Hydro-C-cyano-addition

HCN adds to imines, Schiff bases, hydrazones, oximes, and similar compounds. Cyanide can be added to iminium ions to give α -cyano amines (**83**).

As in **16-50**, the addition to imines has been carried out enantioselectively.¹⁴⁵¹ Chiral ammonium salts have been used with HCN.¹⁴⁵² TMS-CN reacts with *N*-tosyl imines in the presence of $\text{BF}_3 \cdot \text{OEt}_2$ to give the α -cyano *N*-tosyl amine.¹⁴⁵³ In the presence of a chiral zirconium¹⁴⁵⁴ or aluminum¹⁴⁵⁵ catalyst, Bu_3SnCN react with imines to give α -cyanoamines enantioselectively. The reaction of an imine and TMS-CN gives the cyano amine with good enantioselectivity using a chiral scandium catalyst.¹⁴⁵⁶ Titanium catalysts have been used in the presence of a chiral Schiff base.¹⁴⁵⁷ Treatment of an imine with a chiral 1,4,6-triazabicyclo[3.3.0]oct-4-ene and then HCN give the α -cyano amine with good enantioselectivity.¹⁴⁵⁸

The addition of KCN to triisopropylbenzenesulfonyl hydrazones **84** provides an indirect method for achieving the conversion $\text{RR}'\text{CO} \rightarrow \text{RR}'\text{CHCN}$.¹⁴⁵⁹ The reaction is successful for hydrazones of aliphatic aldehydes and ketones.

16-54 The Prins Reaction

The addition of an alkene to formaldehyde in the presence of an acid¹⁴⁶¹ catalyst is called the *Prins reaction*.¹⁴⁶² Three main products are possible; which one predominates depends on the alkene and the conditions. When the product is the 1,3-diol or the dioxane,¹⁴⁶³ the reaction involves addition to the $C=C$ as well as to the $C=O$. The mechanism is one of electrophilic attack on both double bonds. The acid first protonates the $C=O$, and the resulting carbocation is attacked by the $C=C$ to give **85**.

The cation product **85** can undergo loss of H^+ to give the alkene or add water to give the diol.¹⁴⁶⁴ It has been proposed that **85** is stabilized by neighboring-group

¹⁴⁶⁰For an example, see Ferris, J.P.; Sanchez, R.A. *Org. Synth.* **V**, 344.

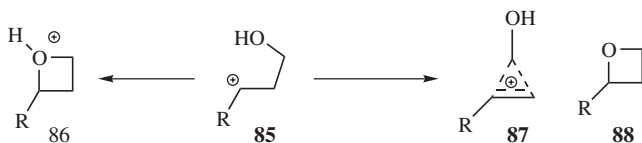

¹⁴⁶¹The Prins reaction has also been carried out with basic catalysts: Griengl, H.; Sieber, W. *Monatsh. Chem.* **1973**, *104*, 1008, 1027.

¹⁴⁶²For reviews, see Adams, D.R.; Bhatnagar, S.P. *Synthesis* **1977**, 661; Isagulyants, V.I.; Khaimova, T.G.; Melikyan, V.R.; Pokrovskaya, S.V. *Russ. Chem. Rev.* **1968**, *37*, 17. For a list of references, see Larock, R.C. *Comprehensive Organic Transformations*, 2nd ed., Wiley-VCH, NY, **1999**, p. 248.

¹⁴⁶³The reaction to produce dioxanes has also been carried out with equimolar mixtures of formaldehyde and another aldehyde RCHO. The R appears in the dioxane on the carbon between the two oxygens: Safarov, M.G.; Nigmatullin, N.G.; Ibatullin, U.G.; Rafikov, S.R. *Doklad. Chem.* **1977**, *236*, 507.

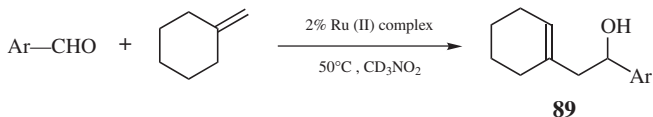

¹⁴⁶⁴Hellin, M.; Davidson, M.; Coussemant, F. *Bull. Soc. Chim. Fr.* **1966**, 1890, 3217.

attraction, with either the oxygen¹⁴⁶⁵ or a carbon¹⁴⁶⁶ stabilizing the charge (**86** and

87, respectively). This stabilization is postulated to explain the fact that with 2-butenes¹⁴⁶⁷ and with cyclohexenes the addition is anti. A backside attack of H₂O on the three- or four-membered ring would account for it. Other products are obtained too, which can be explained on the basis of **86** or **87**.^{1465,1466} Additional evidence for the intermediacy of **86** is the finding that oxetanes (**88**) subjected to the reaction conditions (which would protonate **88** to give **86**) give essentially the same product ratios as the corresponding alkenes.¹⁴⁶⁸ An argument against the intermediacy of **86** and **87** is that not all alkenes show the anti-stereoselectivity mentioned above. Indeed, the stereochemical results are often quite complex, with syn, anti, and nonstereoselective addition reported, depending on the nature of the reactants and the reaction conditions.¹⁴⁶⁹ Since addition to the C=C bond is electrophilic, the reactivity of the alkene increases with alkyl substitution and Markovnikov's rule is followed. The dioxane product may arise from a reaction between the 1,3-diol and formaldehyde¹⁴⁷⁰ (**16-5**) or between **86** and formaldehyde.

Lewis acids, such as SnCl₄, also catalyze the reaction, in which case the species that adds to the alkenes is H₂C⁺-O⁻-SnCl₄.¹⁴⁷¹ Montmorillonite K10 clay containing zinc (IV) has been used to promote the reaction.¹⁴⁷² The reaction can also be catalyzed by peroxides, in which case the mechanism is probably a free-radical one. Other transition metal complexes can be used to form homoallylic alcohols. A typical example is the reaction of methylenecyclohexane with an aryl aldehyde to give **89**.¹⁴⁷³

Samarium iodide promotes this addition reaction.¹⁴⁷⁴ In a related reaction, simple alkene units add to esters in the presence of sodium and liquid ammonia to give an alcohol.¹⁴⁷⁵ Structural variations in the alkene lead to different products. Homoallylic alcohols react with aldehydes in the presence of Montmorillonite KSF clay to give 4-hydroxytetrahydropyrans.¹⁴⁷⁶ A variation of this reaction converts an aryl aldehyde and a homoallylic alcohol to a 4-chlorotetrahydropyran in the presence of InCl_3 .¹⁴⁷⁷ Homoallylic alcohols, protected as $-\text{O}(\text{CHMeOAc})$ react with $\text{BF}_3 \cdot \text{OEt}_2$ and acetic acid to give 4-acetoxytetrahydropyrans or with SnBr_4 to give 4-bromotetrahydropyrans.¹⁴⁷⁸ Homoallylic alcohols with a vinyl silane moiety react with InCl_3 and an aldehyde to give a dihydropyran.¹⁴⁷⁹

A closely related reaction has been performed with activated aldehydes or ketones; without a catalyst such as chloral and acetoacetic ester, but with heat.¹⁴⁸⁰ The product in these cases is a β -hydroxy alkene, and the mechanism is pericyclic:¹⁴⁸¹

This reaction is reversible and suitable β -hydroxy alkenes can be cleaved by heat (17-32). There is evidence that the cleavage reaction occurs by a cyclic mechanism (p. 1551), and, by the principle of microscopic reversibility, the addition mechanism should be cyclic too.¹⁴⁸² Note that this reaction is an oxygen analog of the ene synthesis (15-23). This reaction can also be done with unactivated aldehydes¹⁴⁸³ and ketones¹⁴⁸⁴ if Lewis-acid catalysts such as dimethylaluminum chloride (Me_2AlCl) or ethylaluminum dichloride (EtAlCl_2) are used.¹⁴⁸⁵ Lewis acid catalysts

also increase rates with activated aldehydes.¹⁴⁸⁶ The use of optically active catalysts has given optically active products with high ee.¹⁴⁸⁷

In a related reaction, alkenes can be added to aldehydes and ketones to give reduced alcohols **90**. This has been accomplished by several methods,¹⁴⁸⁸ including treatment with SmI_2 ¹⁴⁸⁹ or Zn and Me_3SiCl ,¹⁴⁹⁰ and by electrochemical¹⁴⁹¹ and photochemical¹⁴⁹² methods. Most of these methods have been used for intramolecular addition and most or all involve free-radical intermediates.

16-55 The Benzoin Condensation

Benzoin aldehyde condensation

When certain aldehydes are treated with cyanide ion, *benzoin*s (**91**) are produced in a reaction called the *benzoin condensation*. The condensation can be regarded as involving the addition of one molecule of aldehyde to the C=O group of another. The reaction only occurs with aromatic aldehydes, but not all of them,¹⁴⁹³ and for glyoxals RCOCHO . The two molecules of aldehyde obviously perform different functions. The one that no longer has a C–H bond in the product is called the *donor*, because it has “donated” its hydrogen to the oxygen of the other molecule, the *acceptor*. Some aldehydes can perform only one of these functions, and hence cannot be self-condensed, though they can often be condensed with a different aldehyde. For example, *p*-dimethylaminobenzaldehyde is not an acceptor but only a donor. Thus it cannot condense with itself, but it can condense with benzaldehyde, which can perform both functions, but is a better acceptor than it is a donor.

The following is the accepted mechanism¹⁴⁹⁴ for this reversible reaction, which was originally proposed by Lapworth in 1903:¹⁴⁹⁵

The key step, the loss of the aldehydic proton, can take place because the acidity of this C–H bond is increased by the electron-withdrawing power of the CN group. Thus, cyanide is a highly specific catalyst for this reaction, because, almost uniquely, it can perform three functions: (1) It acts as a nucleophile; (2) its electron-withdrawing ability permits loss of the aldehydic proton; and (3) having done this, it then acts as a leaving group. Certain thiazolium salts can also catalyze the reaction.¹⁴⁹⁶ In this case, aliphatic aldehydes can also be used¹⁴⁹⁷ (the products are called *acyloins*), and mixtures of aliphatic and aromatic aldehydes give mixed α -hydroxy ketones.¹⁴⁹⁸ The reaction has also been carried out without cyanide, by using the benzoylated cyanohydrin as one of the components in a phase-transfer catalyzed process. By this means, products can be obtained from aldehydes that normally fail to self-condense.¹⁴⁹⁹ The condensation has also been done with excellent enantioselectivity using benzoylformate decarboxylase.¹⁵⁰⁰ Using aryl silyl ketones, $\text{ArC}(=\text{O})\text{SiMe}_2\text{Ph}$, and aldehydes with a lanthanum catalyst, a ‘mixed’ benzoin condensation has been accomplished.¹⁵⁰¹

16-56 Addition of Radicals to C=O, C=S, C=N Compounds

Radical cyclization is not limited to reaction with a C=C unit (see **15-29** and **15-30**), and reactions with both C=N and C=O moieties are known. Reaction of MeON=CH(CH₂)₃CHO with Bu₃SnH and AIBN, for example, led to *trans*-2-(methoxyamino)cyclopentanol in good yield.¹⁵⁰² Conjugated ketones add to aldehyde via the β-carbon under radical conditions (2 equivalents of Bu₃SnH and 0.1 equivalent of CuCl) to give a β-hydroxy ketone.¹⁵⁰³ Addition of radical to the C=N unit of R–C=N–SPh¹⁵⁰⁴ or R–C=N–OBz¹⁵⁰⁵ led to cyclic imines. Radical addition to simple imines leads to aminocycloalkenes.¹⁵⁰⁶ Radical also add to the carbonyl unit of phenylthio esters to give cyclic ketones.¹⁵⁰⁷

N,N-Dimethylaniline reacts with aldehydes under photochemical conditions to give acyl addition via the carbon atom of one of the methyl groups.¹⁵⁰⁸ The reaction of PhNMe₂ and benzaldehyde, for example, gave PhN(Me)CH₂CH(OH)Ph upon photolysis.

ACYL SUBSTITUTION REACTIONS**A. O, N, and S Nucleophiles****16-57** Hydrolysis of Acyl Halides**Hydroxy-de-halogenation**

Acyl halides are so reactive that hydrolysis is easily carried out.¹⁵⁰⁹ In fact, most simple acyl halides must be stored under anhydrous conditions lest they react with water in the air. Consequently, water is usually a strong enough nucleophile for the reaction, though in difficult cases hydroxide ion may be required. The reaction is seldom synthetically useful, because acyl halides are normally prepared from acids. The reactivity order is F < Cl < Br < I.¹⁵¹⁰ If a carboxylic acid is used as the nucleophile, an exchange may take place (see **16-79**). The mechanism¹⁵¹⁰ of hydrolysis can be either S_N1 or tetrahedral, the former occurring in highly polar solvents

and in the absence of strong nucleophiles.¹⁵¹¹ There is also evidence for the S_N2 mechanism in some cases.¹⁵¹²

Hydrolysis of acyl halides is not usually catalyzed by acids, except for acyl fluorides, where hydrogen bonding can assist in the removal of F.¹⁵¹³ There are several methods available for the hydrolysis of acyl fluorides.¹⁵¹⁴

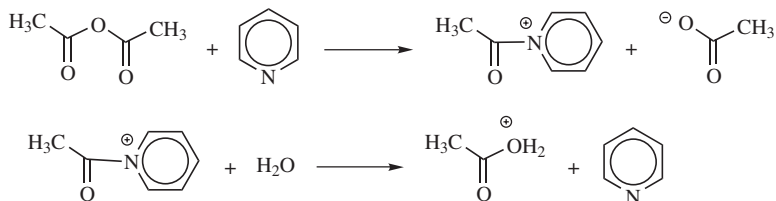

OS II, 74.

16-58 Hydrolysis of Anhydrides

Hydroxy-de-acyloxy-substitution

Anhydrides are somewhat more difficult to hydrolyze than acyl halides, but here too water is usually a strong enough nucleophile. The mechanism is usually tetrahedral.¹⁵¹⁵ Only under acid catalysis does the S_N1 mechanism occur and seldom even then.¹⁵¹⁶ Anhydride hydrolysis can also be catalyzed by bases. Of course, hydroxide ion attacks more readily than water, but other bases can also catalyze the reaction. This phenomenon, called *nucleophilic catalysis* (p. 1258), is actually the result of two successive tetrahedral mechanisms. For example, pyridine catalyzes the hydrolysis of acetic anhydride in this manner.¹⁵¹⁷

Many other nucleophiles similarly catalyze the reaction.

16-59 Hydrolysis of Carboxylic Esters

Hydroxy-de-alkoxylation

Ester hydrolysis is usually catalyzed by acids or bases. Since OR is a much poorer leaving group than halide or OCOR, water alone does not hydrolyze most esters. When bases catalyze the reaction, the attacking species is the more powerful nucleophile OH^- . This reaction is called *saponification* and gives the salt of the acid. Acids catalyze the reaction by making the carbonyl carbon more positive and therefore more susceptible to attack by the nucleophile. Both reactions are equilibrium reactions, so they are practicable only when there is a way of shifting the equilibrium to the right. Since formation of the salt does just this, ester hydrolysis is almost always done for preparative purposes in basic solution, unless the compound is base sensitive. Even in the case of **92**, however, selective base hydrolysis of the ethyl ester gave an 80%

yield of the acid-dimethyl ester (**93**).¹⁵¹⁸ Ester hydrolysis can also be catalyzed¹⁵¹⁹ by metal ions, by cyclodextrins,¹⁵²⁰ by enzymes,¹⁵²¹ and by nucleophiles.¹⁴ Other reagents used to cleave carboxylic esters include Dowex-50,¹⁵²² Me_3SiI ,¹⁵²³ and InCl_3 on moist silica gel using microwave irradiation.¹⁵²⁴ Cleavage of phenolic esters is usually faster than carboxylic esters derived from aliphatic acids. The reagent SmI_2 at -78°C has been used,¹⁵²⁵ ammonium acetate in aqueous methanol,¹⁵²⁶

Amberlyst 15 in methanol,¹⁵²⁷ and phenolic esters have been selectively hydrolyzed in the presence of alkyl esters on alumina with microwave irradiation.¹⁵²⁸ Thiophenol with K_2CO_3 in NMP quantitatively converted methyl benzoate to benzoic acid.¹⁵²⁹ Allylic esters were cleaved with 2% Me_3SiOTf in dichloromethane,¹⁵³⁰ with $CeCl_3 \cdot 7H_2O - NaI$,¹⁵³¹ and with $NaHSO_4 \cdot silica$ gel.¹⁵³² Lactones also undergo the reaction¹⁵³³ (though if the lactone is five- or six-membered, the hydroxy acid often spontaneously reforms the lactone) and thiol esters ($RCOSR'$) give thiols $R'SH$. Typical reagents for this latter transformation include $NaMe$ in methanol,¹⁵³⁴ borohydride exchange resin- $Pd(OAc)_2$ for reductive cleavage of thiol esters to thiols,¹⁵³⁵ and $TiCl_4/Zn$ for the conversion of phenylthioacetates to thiophenols.¹⁵³⁶ Sterically hindered esters are hydrolyzed with difficulty (p. 479), but reaction of 2 equivalents of *t*-BuOK with 1 equivalent of water is effective.¹⁵³⁷ Hindered esters can also be cleaved by sequential treatment with zinc bromide and then water,¹⁵³⁸ with silica gel in refluxing toluene,¹⁵³⁹ and on alumina when irradiated with microwaves.¹⁵⁴⁰ For esters insoluble in water the rate of two-phase ester saponification can be greatly increased by the application of ultrasound,¹⁵⁴¹ and phase-transfer techniques have been applied.¹⁵⁴² Enzymatic hydrolysis of diesters with esterase has been shown to give the hydroxy ester,¹⁵⁴³ and selective hydrolysis of dimethyl succinate to monomethyl succinic acid was accomplished with aq. NaOH in THF.¹⁵⁴⁴ Hydrolysis of vinyl esters leads to ketones, and the reaction of C-substituted vinyl acetates with an esterase derived from *Marchantia polymorpha* gave substituted ketones with high enantioselectivity.¹⁵⁴⁵ Scandium triflate was shown to hydrolyze α -acetoxy ketones to α -hydroxy ketones.¹⁵⁴⁶

TABLE 16.3. (Continued)

Name		
Ingold	IUPAC	Type
B_{AL1}	$D_N + A_N + A_{Xh}D_h$	S_N1
$ \begin{array}{c} \text{O} \\ \parallel \\ \text{R}-\text{C}-\text{OR}' \end{array} \xrightarrow{\text{slow}} \begin{array}{c} \text{O} \\ \parallel \\ \text{R}-\text{C}-\text{O}^\ominus \end{array} + \text{R}' \xrightarrow{\text{H}_2\text{O}} \text{R}'\text{OH}_2^\oplus \xrightarrow{^\ominus\text{OH}} \text{R}'\text{OH} $		
B_{AL2}	$A_N D_N$	S_N2
$ \begin{array}{c} \text{O} \\ \parallel \\ \text{R}-\text{C}-\text{OR}' \end{array} \xrightarrow{^\ominus\text{OH}} \begin{array}{c} \text{O} \\ \parallel \\ \text{R}-\text{C}-\text{O}^\ominus \end{array} + \text{R}'\text{OH} $		

following criteria: (1) acid- or base-catalyzed, (2) unimolecular or bimolecular, and (3) acyl cleavage or alkyl cleavage.¹⁵⁴⁹ All eight of these are S_N1 , S_N2 , or tetrahedral mechanisms. The acid-catalyzed mechanisms are shown with reversible arrows. They are not only reversible, but symmetrical; that is, the mechanisms for ester formation are exactly the same as for hydrolysis, except that H replaces R. Internal proton transfers, such as shown for **B** and **C**, may not actually be direct but may take place through the solvent. There is much physical evidence to show that esters are initially protonated on the carbonyl and not on the alkyl oxygen (Chapter 8, Ref. 17). We have nevertheless shown the A_{AC1} mechanism as proceeding through the ether-protonated intermediate **A**, since it is difficult to envision OR' as a leaving group here. It is of course possible for a reaction to proceed through an intermediate even if only a tiny concentration is present. The designations A_{AC1} , and so on., are those of Ingold. The A_{AC2} and A_{AC1} mechanisms are also called A_2 and A_1 , respectively. Note that the A_{AC1} mechanism is actually the same as the S_{N1cA} mechanism for this type of substrate and that A_{AL2} is analogous to S_{N2cA} . Some authors use A_1 and A_2 to refer to all types of nucleophilic substitution in which the leaving group first acquires a proton. The base-catalyzed reactions are not shown with reversible arrows, since they are reversible only in theory and not in practice. Hydrolyses taking place under neutral conditions are classified as **B** mechanisms.

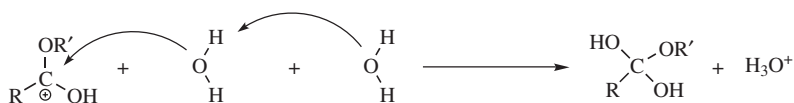

Of the eight mechanisms, seven have actually been observed in hydrolysis of carboxylic esters. The one that has not been observed is the B_{AC1} mechanism.¹⁵⁵⁰ The most common mechanisms are the B_{AC2} for basic catalysis and the A_{AC2} ¹⁵⁵¹

¹⁵⁴⁹For reviews of the mechanisms of ester hydrolysis and formation, see Kirby, A.J., in Bamford, C.H.; Tipper, C.F.H., *Comprehensive Chemical Kinetics*, Vol. 10, 1972, pp. 57–207; Euranto, E.K., in Patai, S. *The Chemistry of Carboxylic Acids and Esters*, Wiley, NY, 1969, pp. 505–588.

¹⁵⁵⁰This is an S_N1 mechanism with OR' as leaving group, which does not happen.

¹⁵⁵¹For a discussion of this mechanism with specific attention to the proton transfers involved, see Zimmermann, H.; Rudolph, J. *Angew. Chem. Int. Ed.* 1965, 4, 40.

for acid catalysis, that is, the two tetrahedral mechanisms. Both involve acyl-oxygen cleavage. The evidence is (1) hydrolysis with H_2^{18}O results in the ^{18}O appearing in the acid and not in the alcohol;¹⁵⁵² (2) esters with chiral R' groups give alcohols with *retention* of configuration;¹⁵⁵³ (3) allylic R' gives no allylic rearrangement;¹⁵⁵⁴ (4) neopentyl R' gives no rearrangement;¹⁵⁵⁵ all these facts indicate that the $\text{O}-\text{R}'$ bond is not broken. It has been concluded that two molecules of water are required in the $\text{A}_{\text{AC}2}$ mechanism.

If this is so, the protonated derivatives **B** and **C** would not appear at all. This conclusion stems from a value of w (see p. 371) of ~ 5 , indicating that water acts as a proton donor here, as well as a nucleophile.¹⁵⁵⁶ Termolecular processes are rare, but in this case the two water molecules are already connected by a hydrogen bond. (A similar mechanism, called $\text{B}_{\text{AC}3}$, also involving two molecules of water, has been found for esters that hydrolyze without a catalyst.¹⁵⁵⁷ Such esters are mostly those containing halogen atoms in the R group.)

The other mechanism involving acyl cleavage is the $\text{A}_{\text{AC}1}$ mechanism. This is rare, being found only where R is very bulky, so that bimolecular attack is sterically hindered, and only in ionizing solvents. The mechanism has been demonstrated for esters of 2,4,6-trimethylbenzoic acid (mesitoic acid). This acid depresses the freezing point of sulfuric acid four times as much as would be predicted from its molecular weight, which is evidence for the equilibrium

In a comparable solution of benzoic acid the freezing point is depressed only twice the predicted amount, indicating only a normal acid-base reaction. Further, a sulfuric acid solution of methyl mesitoate when poured into water gave mesitoic acid, while a similar solution of methyl benzoate similarly treated did not.¹⁵⁵⁸ The $\text{A}_{\text{AC}1}$ mechanism is also found when acetates of phenols or of primary alcohols are

¹⁵⁵⁸Treffers, H.P.; Hammett, L.P. *J. Am. Chem. Soc.* **1937**, *59*, 1708. For other evidence for this mechanism, see Bender, M.L.; Chen, M.C. *J. Am. Chem. Soc.* **1963**, *85*, 37.

hydrolyzed in concentrated (>90%) H₂SO₄ (the mechanism under the more usual dilute acid conditions is the normal A_{AC}2).¹⁵⁵⁹

The mechanisms involving alkyl-oxygen cleavage are ordinary S_N1 and S_N2 mechanisms in which OCOR (an acyloxy group) or its conjugate acid is the leaving group. Two of the three mechanisms, the B_{AL}1 and A_{AL}1 mechanisms, occur most readily when R' comes off as a stable carbocation, that is, when R' is tertiary alkyl, allylic, benzylic, and so on. For acid catalysis, most esters with this type of alkyl group (especially tertiary alkyl) cleave by this mechanism, but even for these substrates, the B_{AL}1 mechanism occurs only in neutral or weakly basic solution, where the rate of attack by hydroxide is so slowed that the normally slow (by comparison) unimolecular cleavage takes over. These two mechanisms have been established by kinetic studies, ¹⁸O labeling, and isomerization of R'.¹⁵⁶⁰ Secondary and benzylic acetates hydrolyze by the A_{AC}2 mechanism in dilute H₂SO₄, but in concentrated acid the mechanism changes to A_{AL}1.¹⁵⁵⁹ Despite its designation, the B_{AL}1 mechanism is actually uncatalyzed (as is the unknown B_{AC}1 mechanism).

The two remaining mechanisms, B_{AL}2 and A_{AL}2, are very rare, the B_{AL}2 because it requires hydroxide ion to attack an alkyl carbon when an acyl carbon is also available,¹⁵⁶¹ and the A_{AL}2 because it requires water to be a nucleophile in an S_N2 process. Both have been observed, however. The B_{AL}2 has been seen in the hydrolysis of β-lactones under neutral conditions¹⁵⁶² (because cleavage of the C—O bond in the transition state opens the four-membered ring and relieves strain), the alkaline hydrolysis of methyl 2,4,6-tri-*tert*-butyl benzoate,¹⁵⁶³ and in the unusual reaction¹⁵⁶⁴

When it does occur, the B_{AL}2 mechanism is easy to detect, since it is the only one of the base-catalyzed mechanisms that requires inversion at R'. However, in the last example given, the mechanism is evident from the nature of the product, since the ether could have been formed in no other way. The A_{AL}2 mechanism has been reported in the acid cleavage of γ-lactones.¹⁵⁶⁵

To sum up the acid-catalysis mechanisms, A_{AC}2 and A_{AL}1 are the common mechanisms, the latter for R' that give stable carbocations, the former for practically

all the rest. The A_{AC1} mechanism is rare, being found mostly with strong acids and sterically hindered R. The A_{AL2} mechanism is even rarer. For basic catalysis, B_{AC2} is almost universal; B_{AL1} occurs only with R' that give stable carbocations and then only in weakly basic or neutral solutions; B_{AL2} is very rare; and B_{AC1} has never been observed.

The above results pertain to reactions in solution. In the gas-phase¹⁵⁶⁶ reactions can take a different course, as illustrated by the reaction of carboxylic esters with MeO^- , which in the gas phase was shown to take place only by the B_{AL2} mechanism,¹⁵⁶⁷ even with aryl esters,¹⁵⁶⁸ where this means that an S_N2 mechanism takes place at an aryl substrate. However, when the gas-phase reaction of aryl esters was carried out with MeO^- ions, each of which was solvated with a single molecule of MeOH or H_2O , the B_{AC2} mechanism was observed.¹⁵⁶⁷

In the special case of alkaline hydrolysis of *N*-substituted aryl carbamates, there is another mechanism¹⁵⁶⁹ involving elimination-addition:¹⁵⁷⁰

This mechanism does not apply to unsubstituted or *N,N*-disubstituted aryl carbamates, which hydrolyze by the normal mechanisms. Carboxylic esters substituted in the α position by an electron-withdrawing group (e.g., CN or COOEt) can also hydrolyze by a similar mechanism involving a ketene intermediate.¹⁵⁷¹

These elimination–addition mechanisms usually are referred to as E1cB mechanisms, because that is the name given to the elimination portion of the mechanism (p. 1488).

The acid-catalyzed hydrolysis of enol esters $\text{RCOOCR}'=\text{CR}$ can take place either by the normal $\text{A}_{\text{AC}}2$ mechanism or by a mechanism involving initial protonation on the double-bond carbon, similar to the mechanism for the hydrolysis of enol ethers given in **10-6**,¹⁵⁷² depending on reaction conditions.¹⁵⁷³ In either case, the products are the carboxylic acid RCOOH and the aldehyde or ketone $\text{R}-\text{CHCOR}'$.

Ester hydrolyses with concomitant decarboxylation are listed at reaction **12-40**.

16-60 Hydrolysis of Amides

Hydroxy-de-amination

Unsubstituted amides (RCONH_2) can be hydrolyzed with either acidic or basic catalysis, the products being, respectively, the free acid and the ammonium ion or the salt of the acid and ammonia. *N*-Substituted (RCONHR') and *N,N*-disubstituted (RCONR'_2) amides can be hydrolyzed analogously, with the primary or secondary amine, respectively (or their salts), being obtained instead of ammonia. Lactams, imides, cyclic imides, hydrazides, and so on., also undergo the reaction. Water alone is not sufficient to hydrolyze most amides,¹⁵⁷⁴ since NH_2 is even a poorer leaving group than OR .¹⁵⁷⁵ Prolonged heating is often required, even with acidic or basic catalysts.¹⁵⁷⁶ Treatment of primary

¹⁵⁷²Alkynyl esters also hydrolyze by this mechanism; see Allen, A.D.; Kitamura, T.; Roberts, K.A.; Stang, P.J.; Tidwell, T.T. *J. Am. Chem. Soc.* **1988**, *110*, 622.

¹⁵⁷³See, for example, Noyce, D.S.; Pollack, R.M. *J. Am. Chem. Soc.* **1969**, *91*, 119, 7158; Monthéard, J.; Camps, M.; Chatzopoulos, M.; Benzaid, A. *Bull. Soc. Chim. Fr.* **1984**, II-109. For a discussion, see Euranto, E.K. *Pure Appl. Chem.* **1977**, *49*, 1009.

¹⁵⁷⁴See Zahn, D. *Eur. J. Org. Chem.* **2004**, 4020.

¹⁵⁷⁵The very low rate of amide hydrolysis by water alone has been measured: Kahne, D.; Still, W.C. *J. Am. Chem. Soc.* **1988**, *110*, 7529.

¹⁵⁷⁶For a list of catalysts and reagents that have been used to hydrolyze amides, with references, see Larock, R.C. *Comprehensive Organic Transformations*, 2nd ed., Wiley-VCH, NY, **1999**, pp. 1976–1977. Also see, Bagno, A.; Lovato, G.; Scorrano, G. *J. Chem. Soc. Perkin Trans. 2* **1993**, 1091.

amides with phthalic anhydride at 250°C and 4 atm gives the carboxylic acid and phthalimide.¹⁵⁷⁷ The conversion of acylhydrazine derivatives to the corresponding carboxylic acid with PhI(OH)(OTs) and water is a variation of amide hydrolysis.¹⁵⁷⁸ Hydrolysis of carbamates (RNHCO₂R) to the corresponding amine can be categorized in this section. Although the product is an amine and the carboxyl unit fragments, this reaction is simply a variation of amide hydrolysis. Strong acids, such as trifluoroacetic acid (in dichloromethane), are usually employed.¹⁵⁷⁹ Treatment of *N*-Boc derivatives (RNHCO₂*t*-Bu) with AlCl₃¹⁵⁸⁰ or with aqueous sodium *tert*-butoxide¹⁵⁸¹ gave the amine. The by-products of this reaction are typically carbon dioxide and isobutylene.

In difficult cases, nitrous acid, NOCl, N₂O₄,¹⁵⁸² or a similar compound can be used (unsubstituted amides only¹⁵⁸³). These reactions involve a diazonium ion (see **13-19**) and are much faster than ordinary hydrolysis; for benzamide the nitrous acid reaction took place 2.5 × 10⁷ times faster than ordinary hydrolysis.¹⁵⁸⁴ Another procedure for difficult cases involves treatment with aqueous sodium peroxide.¹⁵⁸⁵ In still another method, the amide is treated with water and *t*-BuOK at room temperature.¹⁵⁸⁶ The strong base removes the proton from **107**, thus preventing the reaction marked *k*₋₁. A kinetic study has been done on the alkaline hydrolyses of *N*-trifluoroacetyl aniline derivatives.¹⁵⁸⁷ Amide hydrolysis can also be catalyzed by nucleophiles (see p. 1259).

The same framework of eight possible mechanisms that was discussed for ester hydrolysis can also be applied to amide hydrolysis.¹⁵⁸⁸ Both the acid- and base-catalyzed hydrolyses are essentially irreversible, since salts are formed in both

cases. For basic catalysis,¹⁵⁸⁹ the mechanism is B_{AC}2.

There is much evidence for this mechanism, similar to that discussed for ester hydrolysis. A molecular-orbital study on the mechanism of amide hydrolysis is available.¹⁵⁹⁰ In certain cases, kinetic studies have shown that the reaction is second order in OH⁻, indicating that **94** can lose a proton to give **95**.¹⁵⁹¹ Depending on the nature

of R', **95** can cleave directly to give the two negative ions (path *a*) or become N-protonated prior to or during the act of cleavage (path *b*), in which case the products are obtained directly and a final proton transfer is not necessary.¹⁵⁹² Studies of the effect, on the rate of hydrolysis and on the ratio k_{-1}/k_2 , of substituents on the aromatic rings in a series of amides CH₃CONHAr led to the conclusion that path *a* is taken when Ar contains electron-withdrawing substituents and path *b* when electron-donating groups are present.¹⁵⁹³ The presence of electron-withdrawing groups helps stabilize the negative charge on the nitrogen, so that NR'₂⁻ can be a leaving group (path *a*). Otherwise, the C–N bond does not cleave until the nitrogen is protonated (either prior to or in the act of cleavage), so that the leaving group, *even in the base-catalyzed reaction*, is not NR'₂⁻ but the conjugate NHR'₂ (path *b*). Though we have shown formation of **94** as the rate-determining step in the B_{AC}2 mechanism, this is true only at high base concentrations. At lower concentrations of base, the cleavage of **107** or **95** becomes rate determining.¹⁵⁹⁴

For acid catalysis, matters are less clear. The reaction is generally second order, and it is known that amides are primarily protonated on the oxygen (Chapter 8, Ref. 24). Because of these facts it has been generally agreed that most acid-catalyzed amide hydrolysis takes place by the $A_{AC}2$ mechanism.

Further evidence for this mechanism is that a small but detectable amount of ^{18}O exchange (see p. 1256) has been found in the acid-catalyzed hydrolysis of benzamide.¹⁵⁹⁵ (^{18}O exchange has also been detected for the base-catalyzed process,¹⁵⁹⁶ in accord with the $B_{AC}2$ mechanism). Kinetic data have shown that three molecules of water are involved in the rate-determining step,¹⁵⁹⁷ suggesting that, as in the $A_{AC}2$ mechanism for ester hydrolysis (16-59), additional water molecules take part in a process, such as

The four mechanisms involving alkyl-N cleavage (the AL mechanisms) do not apply to this reaction. They are not possible for unsubstituted amides, since the only N-C bond is the acyl bond. They are possible for *N*-substituted and *N,N*-disubstituted amides, but in these cases they give entirely different products and are not amide hydrolyses at all.

This reaction, while rare, has been observed for various *N-tert*-butylamides in 98% sulfuric acid, where the mechanism was the $A_{AL}1$ mechanism,¹⁵⁹⁸ and for certain amides containing an azo group, where a $B_{AL}1$ mechanism was postulated.¹⁵⁹⁹ Of the two first-order acyl cleavage mechanisms, only the $A_{AC}1$ has been observed, in concentrated sulfuric acid solutions.¹⁶⁰⁰ Of course, the diazotization of unsubstituted amides might be expected to follow this mechanism, and there is evidence that this is true.¹⁵⁸⁴

The oxidation of aldehydes to carboxylic acids can proceed by a nucleophilic mechanism, but more often it does not. The reaction is considered in Chapter 19 (19-23). Basic cleavage of β -keto esters and the haloform reaction could be considered at this point, but they are also electrophilic substitutions and are treated in Chapter 12 (12-43 and 12-44).

B. Attack by OR at an Acyl Carbon

16-61 Alcoholysis of Acyl Halides

Alkoxy-de-halogenation

The reaction between acyl halides and alcohols or phenols is the best general method for the preparation of carboxylic esters. It is believed to proceed by a S_N2 mechanism.¹⁶⁰¹ As with 16-57, the mechanism can be S_N1 or tetrahedral.¹⁵¹⁰ Pyridine catalyzes the reaction by the nucleophilic catalysis route (see 16-58). Lewis acids such as lithium perchlorate can be used.¹⁶⁰² The reaction is of wide scope, and many functional groups do not interfere. A base is frequently added to combine with the HX formed. When aqueous alkali is used, this is called the *Schotten–Baumann procedure*, but pyridine is also frequently used. Both R and R' may be primary, secondary, or tertiary alkyl or aryl. Enol esters can also be prepared by this method, though *C*-acylation competes in these cases. In difficult cases, especially with hindered acids or tertiary R', the alkoxide can be used instead of the alcohol.¹⁶⁰³ Activated alumina has also been used as a catalyst, for

tertiary R'.¹⁶⁰⁴ Thallium salts of phenols give very high yields of phenolic esters,¹⁶⁰⁵ and BiOCl is very effective for the preparation of phenolic acetates.¹⁶⁰⁶ Phase-transfer catalysis has been used for hindered phenols.¹⁶⁰⁷ Zinc has been used to couple alcohols and acyl chlorides,¹⁶⁰⁸ and catalytic Cu(acac)₂ and benzoyl chloride was used to prepare the mono-benzoate of ethylene glycol.¹⁶⁰⁹ Selective acylation is possible in some cases.¹⁶¹⁰

Acyl halides react with thiols, in the presence of zinc, to give the corresponding thio-ester.¹⁶¹¹ The reaction of acid chlorides or anhydrides (see **16-62**) with diphenyldiselenide, in the presence of Sm/CoCl₂¹⁶¹² or Sm/CrCl₃¹⁶¹³ gave the corresponding seleno ester (PhSeCOMe).

Acyl halides can also be converted to carboxylic acids by using ethers instead of alcohols, in MeCN in the presence of certain catalysts such as cobalt(II) chloride.¹⁶¹⁴ A variation of this reaction has been reported that uses acetic anhydride.¹⁶¹⁵

This is a method for the cleavage of ethers (see also, **10-49**).

16-63 Esterification of Carboxylic Acids

Alkoxy-de-hydroxylation

The esterification of carboxylic acids with alcohols¹⁶³⁰ is the reverse of 16-60 and can be accomplished only if a means is available to drive the equilibrium to the right.¹⁶³¹ There are many ways of doing this, among which are (1) addition of an excess of one of the reactants, usually the alcohol; (2) removal of the ester or the water by distillation; (3) removal of water by azeotropic distillation; and (4) removal of water by use of a dehydrating agent, silica gel,¹⁶³² or a molecular sieve. When R' is methyl, the most common way of driving the equilibrium is by adding excess MeOH; when R' is ethyl, it is preferable to remove water by azeotropic distillation.¹⁶³³ The most common catalysts are H₂SO₄ and TsOH, although some reactive acids (e.g., formic,¹⁶³⁴ trifluoroacetic¹⁶³⁵) do not require a catalyst. Ammonium salts have been used to initiate esterification,¹⁶³⁶ and boric acid has been used to esterify α -hydroxy acids.¹⁶³⁷ The R' group may be primary or secondary alkyl groups other than methyl or ethyl, but tertiary alcohols usually give carbocations and elimination. Phenols can sometimes be used to prepare phenolic esters, but yields are generally very low. Selective esterification of an aliphatic carboxylic acid in the presence of an aromatic acid was accomplished with NaHSO₄·SiO₂ and methanol.¹⁶³⁸

Diphenylammonium triflate was useful for direct esterification of carboxylic acids with longer chain aliphatic alcohols.¹⁶³⁹ Photoirradiation of carboxylic acid with CBr₄¹⁶⁴⁰ or CCl₄¹⁶⁴¹ in methanol was shown to give the methyl ester, with high selectivity for nonconjugated acids in the case of CBr₄. *O*-Alkylisoureas react

with conjugated carboxylic acids to give the corresponding ester with microwave irradiation,¹⁶⁴² and a polymer-bound *O*-alkylurea has been used as well.¹⁶⁴³

Mixing the carboxylic acid and alcohol with *p*-toluenesulfonic acid (neat), gave the ester in 3 min with microwave irradiation.¹⁶⁴⁴ Esterification has also been accomplished using ionic liquids as the reaction medium,¹⁶⁴⁵ and a solid-state esterification was reported on P₂O₅/SiO₂.¹⁶⁴⁶ Diols are converted to the monoacetate by heating with acetic acid on a zeolite.¹⁶⁴⁷

Both γ - and δ -hydroxy acids such as **97** are easily converted to a lactone by treatment with acids, or often simply on standing, but larger and smaller lactone rings cannot be made in this manner, because polyester formation occurs more readily.¹⁶⁴⁸ Often the conversion of a group, such as keto or halogen, γ or δ to a carboxyl group, to a hydroxyl group gives the lactone directly, since the hydroxy acid cyclizes too rapidly for isolation. β -Substituted β -hydroxy acids can be converted to β -lactones by treatment with benzenesulfonyl chloride in pyridine at 0–5°C.¹⁶⁴⁹ ϵ -Lactones (seven-membered rings) have been made by cyclization of ϵ -hydroxy acids at high dilution.¹⁶⁵⁰ Macrocyclic lactones¹⁶⁵¹ can be prepared indirectly in very good yields by conversion of the hydroxy acids to 2-pyridinethiol esters and adding these to refluxing xylene.¹⁶⁵² Palladium-catalyzed aromatic carboxylation

reactions generated carboxylic acids *in situ*, and when an alcohol unit is present elsewhere in the molecule cyclization gives the corresponding lactone.¹⁶⁵³

A closely related method, which often gives higher yields of a macrocyclic lactone, involves treatment of the hydroxy acids with 1-methyl- or 1-phenyl-2-halopyridinium salts, especially 1-methyl-2-chloropyridinium iodide (*Mukaiyama's reagent*).¹⁶⁵⁴ Another method uses organotin oxides¹⁶⁵⁵ and both $\text{TiCl}_4/\text{AgClO}_4$ ¹⁶⁵⁶ and $\text{TiCl}_2(\text{OSO}_2\text{CF}_3)_2$ ¹⁶⁵⁷ have been used.

Esterification is catalyzed by acids (not bases) in ways that were discussed on p. 1402.¹⁵⁴⁹ The mechanisms are usually $A_{AC}2$, but $A_{AC}1$ and $A_{AL}1$ have also been observed.¹⁶⁵⁸ Certain acids, such as 2,6-di-ortho-substituted benzoic acids, cannot be esterified by the $A_{AC}2$ mechanism because of steric hindrance (p. 481). In such cases, esterification can be accomplished by dissolving the acid in 100% H_2SO_4 (forming the ion RCO^+) and pouring the solution into the alcohol ($A_{AC}1$ mechanism). The reluctance of hindered acids to undergo the normal $A_{AC}2$ mechanism can sometimes be put to advantage when, in a molecule containing two COOH groups,

only the less hindered one is esterified. The $A_{AC}1$ pathway cannot be applied to unhindered carboxylic acids.

Another way to esterify a carboxylic acid is to treat it with an alcohol in the presence of a dehydrating agent.¹⁶³¹ One of these is dicyclohexylcarbodiimide (DCC), which is converted in the process to dicyclohexylurea (DHU). The mechanism¹⁶⁵⁹ has much in common with the nucleophilic catalysis mechanism; the acid is converted to a compound with a better leaving group. However, the conversion is not by a tetrahedral mechanism (as it is in nucleophilic catalysis), since the C–O bond remains intact during this step:

Evidence for this mechanism was the preparation of *O*-acylureas similar to **98** and the finding that when catalyzed by acids they react with alcohols to give esters.¹⁶⁶⁰ Hindered tertiary alcohols can be coupled via DCC to give the hindered ester.¹⁶⁶¹ A polymer-bound carbodiimide has been used to prepare macrocyclic lactones.¹⁶⁶² In at least one case, the reaction of HOOCCH_2CN with DCC and *tert*-butanol gave the *tert*-butyl ester via a ketene intermediate.¹⁶⁶³

¹⁶⁶³Nahmany, M.; Melman, A. *Org. Lett.* **2001**, *3*, 3733.

There are limitations to the use of DCC; yields are variable and *N*-acylureas are side products. Many other dehydrating agents¹⁶⁶⁴ have been used, including DCC and an aminopyridine,¹⁶⁶⁵ Amberlyst-15,¹⁶⁶⁶ chlorosilanes,¹⁶⁶⁷ MeSO₂Cl-Et₃N,¹⁶⁶⁸ and *N,N'*-carbonyldiimidazole(**99**).¹⁶⁶⁹ In the latter case, imidazolides (**100**) are intermediates that readily react with alcohols.

It is known that the Lewis acid BF₃ promotes the esterification by converting the acid to RCO⁺–BF₃[–]OH, so the reaction proceeds by an A_{AC}1 type of mechanism. The use of BF₃-etherate is simple and gives high yields.¹⁶⁷⁰ Other Lewis acids can be used.¹⁶⁷¹ Esterification has been done using a LaY zeolite.¹⁶⁷²

Carboxylic esters can also be prepared by treating carboxylic acids with *tert*-butyl ethers and acid catalysts.¹⁶⁷³

Carboxylic acids can be converted to *tert*-butyl esters by treatment with *tert*-butyl 2,2,2-trichloroacetimidate (see **10-10**) and BF₃·OEt₂.¹¹⁷³ Carboxylic esters can be formed from the carboxylate anion and a suitable alkylating agent (**10-26**).

Thioesters of the type RSC(=S)R' (a dithiocarboxylic ester) and RSC(C=O)R' (a thiocarboxylic ester) can be generated by reaction of carboxylic acids with thiols.

16-64 Transesterification

Alkoxy-de-alkoxylation

Transesterification¹⁶⁷⁷ is catalyzed¹⁶⁷⁸ by acids¹⁶⁷⁹ or bases,¹⁶⁸⁰ or performed under neutral conditions.¹⁶⁸¹ It is an equilibrium reaction and must be shifted in the desired direction. In many cases low-boiling esters can be converted to higher boiling ones by the distillation of the lower boiling alcohol as fast as it is formed. Reagents used to catalyze¹⁶⁸² transesterification include Montmorillonite K10¹⁶⁸³ and various Lewis acids.¹⁶⁸⁴ A polymer-bound siloxane has been used to induce transesterification.¹⁶⁸⁵ This reaction has been used as a method for the acylation of a primary OH in the presence of a secondary OH.¹⁶⁸⁶ Regioselectivity has

also been accomplished by using enzymes (lipases) as catalysts.¹⁶⁸⁷ Lactones, such as **101**, are easily opened by treatment with alcohols¹⁶⁸⁸ to give open-chain hydroxy esters.

Transesterification has been carried out with phase-transfer catalysts, without an added solvent.¹⁶⁸⁹ Nonionic superbases (see p. 365) of the type P(RNCH₂CH₂)₃N catalyze the transesterification of carboxylic acid esters at 25°C.¹⁶⁹⁰ Silyl esters (R'CO₂SiR₃) have been converted to alkyl esters (R'CO₂R) via reaction with alkyl halides and tetrabutylammonium fluoride.¹⁶⁹¹ Thioesters are converted to phenolic esters by treatment with triphosgene–pyridine and then phenol.¹⁶⁹²

Transesterification occurs by mechanisms¹⁶⁹³ that are identical with those of ester hydrolysis, except that ROH replaces HOH (by the acyl-oxygen fission mechanisms). When alkyl fission takes place, the products are the *acid* and the *ether*:

Therefore, transesterification reactions frequently fail when R' is tertiary, since this type of substrate most often reacts by alkyl–oxygen cleavage. In such cases, the reaction is of the Williamson type with OCOR as the leaving group (see **10-10**).

With enol esters such as **102**, reaction with an alcohol gives an ester and the enol of a ketone, which readily tautomerizes to the ketone as shown. Hence, enol esters are good acylating agents for alcohols.¹⁶⁹⁴ This transformation has been

accomplished in ionic liquid media,¹⁶⁹⁵ and there is a PdCl₂/CuCl₂ mediated version.¹⁶⁹⁶ Isopropenyl acetate can also be used to convert other ketones to the corresponding enol acetates in an exchange reaction:¹⁶⁹⁷

Enol esters can also be prepared in the opposite type of exchange reaction, catalyzed by mercuric acetate¹⁶⁹⁸ or Pd(II) chloride,¹⁶⁹⁹ for example,

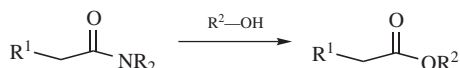

A closely related reaction is equilibration of a dicarboxylic acid and its diester to produce monoesters: The reaction of a carboxylic acid with ethyl acetate, in the presence of NaHSO₄•SiO₂, was shown to give the corresponding ethyl ester.¹⁷⁰⁰ Iodine catalyzes the transesterification of β-keto esters.¹⁷⁰¹

16-65 Alcoholysis of Amides

Alkoxy-deamidation

Alcoholysis of amides is possible,¹⁷⁰² although it is usually difficult. It has been most common with the imidazolidine type of amides (e.g., **100**). For other amides, an activating agent is usually necessary before the alcohol will replace the NR₂ unit. Dimethylformamide, however, reacted with primary alcohols in the presence of 2,4,6-trichloro-1,3,5-pyrazine (cyanuric acid) to give the corresponding formate ester.¹⁷⁰³ Treatment of an amide with triflic anhydride (CF₃SO₂OSO₂CF₃) in the

presence of pyridine and then with an excess of alcohol leads to the ester,¹⁷⁰⁴ as does treatment with $\text{Me}_2\text{NCH}(\text{OMe})_2$ followed by the alcohol.¹⁷⁰⁵ Trimethyloxonium tetrafluoroborate converted primary amides to methyl esters.¹⁷⁰⁶ The reaction of acetanilide derivatives with sodium nitrite in the presence of acetic anhydride-acetic acid leads to phenolic acetates.¹⁷⁰⁷ Acyl hydrazides (RCONHNH_2) were converted to esters by reaction with alcohols and various reagents,¹⁷⁰⁸ and methoxamides (RCONHOMe) were converted to esters with TiCl_4/ROH .¹⁷⁰⁹ The reaction of an oxazolidinone amide **103** with methanol and 10% MgBr_2 gave the corresponding methyl ester.¹⁷¹⁰

C. Attack by OCOR at an Acyl Carbon

16-66 Acylation of Carboxylic Acids With Acyl Halides

Acyloxy-de-halogenation

Unsymmetrical, as well as symmetrical, anhydrides are often prepared by the treatment of an acyl halide with a carboxylic acid salt. Cobalt(II) chloride (CoCl_2) has been used as a catalyst.¹⁷¹¹ If a metallic salt is used, Na^+ , K^+ , or Ag^+ are the most common cations, but more often pyridine or another tertiary amine is added to the free acid and the resulting salt is subsequently treated with the acyl halide. Mixed formic anhydrides are prepared from sodium formate and an aryl halide, by use of a solid-phase copolymer of pyridine-1-oxide.¹⁷¹² Symmetrical anhydrides can be prepared by reaction of the acyl halide with aq. NaOH or

16-67 Acylation of Carboxylic Acids With Carboxylic Acids

Acyloxy-de-hydroxylation

Anhydrides can be formed from two molecules of an ordinary carboxylic acid only if a dehydrating agent is present so that the equilibrium can be driven to the right. Common dehydrating agents¹⁷¹⁵ are acetic anhydride, trifluoroacetic anhydride, dicyclohexylcarbodiimide,¹⁷¹⁶ and P_2O_5 . Triphenylphosphine/ CCl_3CN with triethylamine has also been used with benzoic acid derivatives.¹⁷¹⁷ The method is very poor for the formation of mixed anhydrides, which in any case generally undergo disproportionation to the two simple anhydrides when they are heated. However, simple heating of dicarboxylic acids does give cyclic anhydrides, provided that the ring formed contains five, six, or seven members, for example,

Malonic acid and its derivatives, which would give four-membered cyclic anhydrides, do not give this reaction when heated but undergo decarboxylation (12-40) instead.

Carboxylic acids exchange with amides and esters; these methods are sometimes used to prepare anhydrides if the equilibrium can be shifted, for example,

¹⁷¹³Plusquellec, D.; Roulleau, F.; Lefeuvre, M.; Brown, E. *Tetrahedron* **1988**, *44*, 2471; Wang, J.; Hu, Y.; Cui, W. *J. Chem. Res. (S)* **1990**, 84.

¹⁷¹⁴Hu, Y.; Wang, J.-X.; Li, S. *Synth. Commun.* **1997**, *27*, 243.

¹⁷¹⁵For lists of other dehydrating agents with references, see Larock, R.C. *Comprehensive Organic Transformations*, 2nd ed., Wiley-VCH, NY, **1999**, pp. 1930–1932; Ogliaruso, M.A.; Wolfe, J.F., in Patai, S. *The Chemistry of Acid Derivatives*, pt.1, Wiley, NY, **1979**, pp. 437–438.

¹⁷¹⁶For example, see Schüssler, H.; Zahn, H. *Chem. Ber.* **1962**, *95*, 1076; Rammler, D.H.; Khorana, H.G. *J. Am. Chem. Soc.* **1963**, *85*, 1997. See also, Hata, T.; Tajima, K.; Mukaiyama, T. *Bull. Chem. Soc. Jpn.* **1968**, *41*, 2746.

¹⁷¹⁷Kim, J.; Jang, D.O. *Synth. Commun.* **2001**, *31*, 395.

Enolic esters are especially good for this purpose, because the equilibrium is shifted by formation of the ketone.

The combination of KF with 2-acetoxypropene under microwave conditions was effective.¹⁷¹⁸ Carboxylic acids also exchange with anhydrides; indeed, this is how acetic anhydride acts as a dehydrating agent in this reaction.

Anhydrides can be formed from certain carboxylic acid salts; for example, by treatment of trimethylammonium carboxylates with phosgene:¹⁷¹⁹

or of thallium(I) carboxylates with thionyl chloride,¹⁶⁰⁵ or of sodium carboxylates with CCl₄ and a catalyst such as CuCl or FeCl₂.¹⁷²⁰

16-68 Preparation of Mixed Organic-Inorganic Anhydrides

Nitrooxy-de-acyloxy-substitution

Mixed organic-inorganic anhydrides are seldom isolated, though they are often intermediates when acylation is carried out with acid derivatives catalyzed by inorganic acids. Sulfuric, perchloric, phosphoric, and other acids form similar anhydrides, most of which are unstable or not easily obtained because the equilibrium lies in the wrong direction. These intermediates are formed from amides, carboxylic acids, and esters, as well as anhydrides. Organic anhydrides of phosphoric acid are more stable than most others and, for example, RCOOPO(OH)₂ can be prepared in the form of its salts.¹⁷²¹ Mixed anhydrides of carboxylic and sulfonic acids (RCOOSO₂R') are obtained in high yields by treatment of sulfonic acids with acyl halides or (less preferred) anhydrides.¹⁷²²

16-69 Attack by SH or SR at an Acyl Carbon¹⁷²³

Thiol acids and thiol esters¹⁷²⁴ can be prepared in this manner, which is analogous to **16-57** and **16-64**. Anhydrides¹⁷²⁵ and aryl esters (RCOOAr)¹⁷²⁶ are also used as substrates, but the reagents in these cases are usually HS⁻ and RS⁻. Thiol esters can also be prepared by treatment of carboxylic acids with P₄S₁₀-Ph₃SbO,¹⁷²⁷ or with a thiol RSH and either polyphosphate ester or phenyl dichlorophosphate PhOPOCl₂.¹⁷²⁸ Esters RCOOR' can be converted to thiol esters RCOSR² by treatment with trimethylsilyl sulfides Me₃SiSR² and AlCl₃.¹⁷²⁹

Alcohols, when treated with a thiol acid and zinc iodide, give thiol esters (R'COSR)¹⁷³⁰

E. Attack by Nitrogen at an Acyl Carbon¹⁷⁴⁴

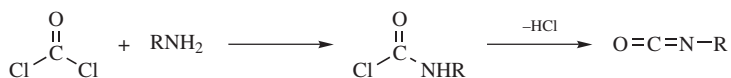

16-72 Acylation of Amines by Acyl Halides

Amino-de-halogenation

The treatment of acyl halides with ammonia or amines is a very general reaction for the preparation of amides.¹⁷⁴⁵ The reaction is highly exothermic and must be carefully controlled, usually by cooling or dilution. Ammonia gives unsubstituted amides, primary amines give *N*-substituted amides,¹⁷⁴⁶ and secondary amines give *N,N*-disubstituted amides. Arylamines can be similarly acylated. Hydroxamic acids have been prepared by this route.¹⁷⁴⁷ In some cases, aqueous alkali is added to combine with the liberated HCl. This is called the *Schotten-Baumann procedure*, as in **16-61**. Activated zinc can be used to increase the rate of amide formation when hindered amines and/or acid chlorides are used.¹⁷⁴⁸ An indium-mediated amidation reaction¹⁷⁴⁹ and a BiOCl-mediated reaction¹⁷⁵⁰ have been reported. A variation of this basic reaction uses DMF with acyl halides to give *N,N*-dimethylamides.¹⁷⁵¹ A solvent-free reaction was reported using DABCO and methanol.¹⁷⁵²

Hydrazine and hydroxylamine also react with acyl halides to give, respectively, hydrazides (RCONHNH₂)¹⁷⁵³ and hydroxamic acids (RCONHOH).¹⁷⁵⁴ When phosgene is the acyl halide, both aliphatic and aromatic primary amines give chloroformamides (ClCONHR) that lose HCl to give isocyanates (RNCO).¹⁷⁵⁵ This is one of the most common methods for

¹⁷⁵⁵For reviews of the preparation and reactions of isocyanates and isothiocyanates, see, respectively, the articles by Richter, R.; Ulrich, H. pp. 619–818, and Drobnica, L.; Kristián, P.; Augustín, J. pp. 1003–1221, in Patai S. *The Chemistry of Cyanates and Their Thio Derivatives*, pt. 2, Wiley, NY, **1977**.

the preparation of isocyanates.¹⁷⁵⁶ Thiophosgene,¹⁷⁵⁷ similarly treated, gives isothiocyanates. A safer substitute for phosgene in this reaction is trichloromethyl chloroformate CCl₃OCOC(=O)Cl.¹⁷⁵⁸ When chloroformates ROCOCl are treated with primary amines, carbamates ROCONHR' are obtained.¹⁷⁵⁹ An example of this reaction is the use of benzyl chloroformate to protect the amino group of amino acids and peptides.

The PhCH₂OCO group in **107** is called the carbobenzyoxy group,¹⁷⁶⁰ and is often abbreviated Cbz or Z. Another important group similarly used is the *tert*-butoxycarbonyl group Me₃COCO, abbreviated as Boc. In this case, the chloride (Me₃COCOC(=O)Cl) is unstable, so the anhydride, (Me₃COCO)₂O, is used instead, in an example of **16-73**. Amino groups in general are often protected by conversion to amides.¹⁷⁶¹ The treatment of acyl halides with lithium nitride gives *N,N*-diacyl amides (triacylamines), **108**.¹⁷⁶² The reactions proceed by the tetrahedral mechanism.¹⁷⁶³

A novel variation of this reaction uses nitrogen gas as the nitrogen source in the amide. The reaction of benzoyl chloride with TiCl₄/Li/Me₃SiCl/CsF and N₂, gave a 77% yield of benzamide.¹⁷⁶⁴

An interesting variation of this transformation reacts carbamoyl chlorides with organocuprates to give the corresponding amide.¹⁷⁶⁵

16-73 Acylation of Amines by Anhydrides

Amino-de-acyloxy-substitution

This reaction, similar in scope and mechanism¹⁷⁶⁶ to **16-72**, can be carried out with ammonia or primary or secondary amines.¹⁷⁶⁷ Note that there is a report where a tertiary amine (an *N*-alkylpyrrolidine) reacted with acetic anhydride at 120°C, in the presence of a BF₃•etherate catalyst, to give *N*-acetylpyrrolidine (an acylative dealkylation).¹⁷⁶⁸ Amino acids can be *N*-acylated using acetic anhydride and ultrasound.¹⁷⁶⁹ However, ammonia and primary amines can also give imides, in which two acyl groups are attached to the nitrogen. The conversion of cyclic anhydrides to cyclic imides is generally facile,¹⁷⁷⁰ although elevated temperatures are occasionally required to generate the imide.¹⁷⁷¹ Microwave irradiation of formamide and a cyclic anhydride generates the cyclic imide.¹⁷⁷² Cyclic imides have also been formed in ionic liquids.¹⁷⁷³ Cyclic imides were also formed by microwave irradiation of a polymer-bound phthalate after initial reaction with an amine.¹⁷⁷⁴

The second step for imide formation, which is much slower than the first, is the attack of the amide nitrogen on the carboxylic carbon. Unsubstituted and *N*-substituted amides have been used instead of ammonia. Since the other product

¹⁷⁷³In bmim PF₆, 1-butyl-3-methylimidazolium hexafluorophosphate: Le, Z.-G.; Chen, Z.-C.; Hu, Y.; Zheng, Q.-G. *Synthesis* **2004**, 995.

¹⁷⁷⁴Martin, B.; Sekljic, H.; Chassaing, C. *Org. Lett.* **2003**, *5*, 1851.

of this reaction is RCOOH, this is a way of “hydrolyzing” such amides in the absence of water.¹⁷⁷⁵

Even though formic anhydride is not a stable compound (see p. 723), amines can be formylated with the mixed anhydride of acetic and formic acids (HCOO-COME)¹⁷⁷⁶ or with a mixture of formic acid and acetic anhydride. Acetamides are not formed with these reagents. Secondary amines can be acylated in the presence of a primary amine by conversion to their salts and addition of 18-crown-6.¹⁷⁷⁷ The crown ether complexes the primary ammonium salt, preventing its acylation, while the secondary ammonium salts, which do not fit easily into the cavity, are free to be acylated. Dimethyl carbonate can be used to prepare methyl carbamates in a related procedure.¹⁷⁷⁸ *N*-Acetylsulfonamides were prepared from acetic anhydride and a primary sulfonamide, catalyzed by Montmorillonite K10–FeO¹⁷⁷⁹ or sulfuric acid.¹⁷⁸⁰

The reaction of anhydrides with aryl azides, in the presence of Me₃SiCl and NaI, gives *N*-aryl imides.¹⁷⁸¹

16-74 Acylation of Amines by Carboxylic Acids

Amino-de-hydroxylation

When carboxylic acids are treated with ammonia or amines, salts are obtained. The salts of ammonia or primary or secondary amines can be pyrolyzed to give amides,¹⁷⁸² but the method is less convenient than **16-72**, **16-73**, and **16-75** and is seldom of preparative value.¹⁷⁸³ Heating in the presence of a base such as hexamethyldisilazide makes the amide-forming process more efficient.¹⁷⁸⁴ Boronic acids catalyze the direct conversion of carboxylic acid and amine to amides.¹⁷⁸⁵

¹⁷⁸⁵Ishihara, K.; Kondo, S.; Yamamoto, H. *Synlett* **2001**, 1371.

Polymer-bound reagents have also been used.¹⁷⁸⁶ The synthetically important Weinreb amides [RCON(Me)OMe, see **16-82**] can be prepared from the carboxylic acid and MeO(Me)NH•HCl in the presence of tributylphosphine and 2-pyridine-*N*-oxide disulfide.¹⁷⁸⁷ Di(2-pyridyl)carbonate has been used in a related reaction that generates amides directly.¹⁷⁸⁸ The reaction of a carboxylic acid and imidazole under microwave irradiation gives the amide.¹⁷⁸⁹ Microwave irradiation of a secondary amine, formic acid, 2-chloro-4,6-dimethoxy[1,3,5]triazine, and a catalytic amount of DMAP (4-dimethylaminopyridine) leads to the formamide.¹⁷⁹⁰ Ammonium bicarbonate and formamide converts acids to amides with microwave irradiation.¹⁷⁹¹ Lactams are readily produced from γ - or δ -amino acids,¹⁷⁹² for example,

This lactamization process can be promoted by enzymes, such as pancreatic porcine lipase.¹⁷⁹³ Reduction of ω -azido carboxylic acids leads to macrocyclic lactams.¹⁷⁹⁴

Although treatment of carboxylic acids with amines does not directly give amides, the reaction can be made to proceed in good yield at room temperature or slightly above by the use of coupling agents,¹⁷⁹⁵ the most important of which is dicyclohexylcarbodiimide. This reagent is very convenient and is used¹⁷⁹⁶ a great deal in peptide synthesis.¹⁷⁹⁷ A polymer-supported carbodiimide has been used.¹⁷⁹⁸ The mechanism is probably the same as in **16-63** up to the formation

or by treatment with trisalkylaminoboranes, $B(NHR')_3$, with trisdialkylaminoboranes, $B(NR'_2)_3$,¹⁸¹²

or with bis(diorganoamino)magnesium reagents $(R_2N)_2Mg$.¹⁸¹³ The reaction of thiocarboxylic acids and azides, in the presence of triphenylphosphine, gives the corresponding amide.¹⁸¹⁴

An important technique, discovered by R.B. Merrifield in 1963¹⁸¹⁵ and since used for the synthesis of many peptides,¹⁸¹⁶ is called *solid phase synthesis* or *polymer-supported synthesis*.¹⁸¹⁷ The reactions used are the same as in ordinary synthesis, but one of the reactants is anchored onto a solid polymer. For example, if it is desired to couple two amino acids (to form a dipeptide), the polymer selected might be polystyrene with CH_2Cl side chains. One of the amino acids, protected by a *tert*-butoxycarbonyl group (Boc), would then be coupled to the side chains. It is not necessary that all the side chains be converted, but a random selection will be. The Boc group is then removed by hydrolysis with trifluoroacetic acid in CH_2Cl_2 and the second amino acid is coupled to the first, using DCC or some other coupling agent. The second Boc group is removed, resulting in a dipeptide that is still anchored to the polymer. If this dipeptide is the desired product, it can be cleaved from the polymer by various methods,¹⁸¹⁸ one of which is treatment with HF. If a longer peptide is wanted, additional amino acids can be added by repeating the requisite steps.

¹⁸¹⁸For some of these methods, see Whitney, D.B.; Tam, J.P.; Merrifield, R.B. *Tetrahedron* **1984**, *40*, 4237.

The basic advantage of the polymer-support techniques is that the polymer (including all chains attached to it) is easily separated from all other reagents, because it is insoluble in the solvents used. Excess reagents, other reaction products (e.g., dicyclohexylurea), side products, and the solvents themselves are quickly washed away. Purification of the polymeric species is rapid and complete. The process can even be automated,¹⁸¹⁹ to the extent that six or more amino acids can be added to a peptide chain in one day. Commercial automated peptide synthesizers are now available.¹⁸²⁰

Although the solid-phase technique was first developed for the synthesis of peptide chains and has seen considerable use for this purpose, it has also been used to synthesize chains of polysaccharides and polynucleotides; in the latter case, solid-phase synthesis has almost completely replaced synthesis in solution.¹⁸²¹ The technique has been applied less often to reactions in which only two molecules are brought together (nonrepetitive syntheses), but many examples have been reported.¹⁸²² Combinatorial chemistry had its beginning with the Merrifield synthesis, particularly when applied to peptide synthesis, and continues as an important part of modern organic chemistry.¹⁸²³

16-75 Acylation of Amines by Carboxylic Esters

Amino-de-alkoxylation

The conversion of carboxylic esters to amides is a useful reaction, and unsubstituted, *N*-substituted, and *N,N*-disubstituted amides can be prepared this way from the appropriate amine.¹⁸²⁴ Both R and R' can be alkyl or aryl, but an especially

good leaving group is *p*-nitrophenyl. Ethyl trifluoroacetate was found to react selectively with primary amines to form the corresponding trifluoroacetyl amide.¹⁸²⁵ Many simple esters (R = Me, Et, etc.) are not very reactive, and strongly basic catalysis has been used in such cases,¹⁸²⁶ but catalysis by cyanide ion¹⁸²⁷ MgBr₂,¹⁸²⁸ InI₃,¹⁸²⁹ and acceleration by high pressure¹⁸³⁰ have been reported. Methyl esters have been converted to the corresponding amide under microwave irradiation,¹⁸³¹ and also ethyl esters.¹⁸³² Lithium amides have been used to convert esters to amides as well.¹⁸³³ β-Keto esters undergo the reaction especially easily.¹⁸³⁴ In another procedure, esters are treated with dimethylaluminum amides (Me₂AlNRR') to give good yields of amides under mild conditions.¹⁸³⁵ The reagents are easily prepared from Me₃Al and NH₃ or a primary or secondary amine or their salts. This is particularly effective when a reactive substituent, such as a primary halide, is present elsewhere in the molecule.¹⁸³⁶ Tin reagents, such as Sn[N(TMS)₂]₂, in the presence of an amine can also be used to convert an ester to an amide.¹⁸³⁷ This reagent can also be used to convert β-amino esters to β-lactams.¹⁸³⁸ Aniline was treated with *n*-butyllithium to form the lithium amide, which reacted with an ester to give the amide.¹⁸³⁹ The ester-to-amide conversion has also been accomplished electrochemically, by passing electric current in the cathodic compartment.¹⁸⁴⁰ An enzyme-mediated amidation is known using amino cyclase I.¹⁸⁴¹ The reaction of dimethyl carbonate and an amine is an effective way to prepare methyl carbamates.¹⁸⁴²

As in **16-72**, hydrazides and hydroxamic acids can be prepared from carboxylic esters, with hydrazine and hydroxylamine, respectively. Both hydrazine and hydroxylamine react more rapidly than ammonia or primary amines (the alpha effect, p. 495). Imidates $\text{RC}(=\text{NH})\text{OR}'$ give amidines $\text{RC}(=\text{NH})\text{NH}_2$. Lactones, when treated with ammonia or primary amines, give lactams. Lactams are also produced from γ - and δ -amino esters in an internal example of this reaction. Isopropenyl formate is a useful compound for the formylation of primary and secondary amines.¹⁸⁴³

Although more studies have been devoted to the mechanism of the acylation of amines with carboxylic esters than with other reagents, the mechanistic details are not yet entirely clear.¹⁸⁴⁴ In its broad outlines, the mechanism appears to be essentially $\text{B}_{\text{AC}}2$.¹⁸⁴⁵ Under the normal basic conditions, the reaction is general base-catalyzed,¹⁸⁴⁶ indicating that a proton is being transferred in the rate-determining step and that two molecules of amine are involved.¹⁸⁴⁷

Alternatively, another base, such as H_2O or OH^- , can substitute for the second molecule of amine. With some substrates and under some conditions, especially at low pH, the breakdown of **111** can become rate determining.¹⁸⁴⁸ The reaction also takes place under acidic conditions and is general acid catalyzed, so that

breakdown of **111** is rate determining and proceeds as follows:¹⁸⁴⁹

HA may be $R^2NH_3^+$ or another acid. Intermediate **111** may or may not be further protonated on the nitrogen. Even under basic conditions, a proton donor may be necessary to assist leaving-group removal. Evidence for this is that the rate is lower with NR_2^- in liquid ammonia than with NHR_2 in water, apparently owing to the lack of acids to protonate the leaving oxygen.¹⁸⁵⁰

In the special case of β -lactones, where small-angle strain is an important factor, alkyl-oxygen cleavage is observed ($B_{AL}2$ mechanism, as in the similar case of hydrolysis of β -lactones, **16-59**), and the product is not an amide but a β -amino acid (β -alanine).

A similar result has been found for certain sterically hindered esters.¹⁸⁵¹ This reaction is similar to **10-31**, with $OCOR$ as the leaving group. Other lactones have been opened to ω -hydroxy amides with $Dibal:BnNH_2$.¹⁸⁵²

amines (in the form of their salts) are the most common reagents. Boron trifluoride can be added to complex with the leaving ammonia. Neutral amines also react in some cases to give the new amide.¹⁸⁵⁴ The reaction is often used to convert urea to substituted ureas: $\text{NH}_2\text{CONH}_2 + \text{RNH}_3^+ \rightarrow \text{NH}_2\text{CONHR} + \text{NH}_4^+$.¹⁸⁵⁵ An *N*-aryl group of a urea can be converted to a *N,N*-dialkyl group by heating the urea with the amine in an autoclave.¹⁸⁵⁶ *N*-*R*-Substituted amides are converted to *N*-*R'*-substituted amides by treatment with N_2O_4 to give an *N*-nitroso compound, followed by treatment of this with a primary amine $\text{R}'\text{NH}_2$.¹⁸⁵⁷ Lactams can be converted to ring-expanded lactams if

a side chain containing an amino group is present on the nitrogen. A strong base is used to convert the NH_2 to NH^- , which then acts as a nucleophile, expanding the ring by means of a transamidation.¹⁸⁵⁸ The discoverers call it the *Zip reaction*, by analogy with the action of zippers.¹⁸⁵⁹

Lactams can be opened to ω -amino amides by reaction with amines at 10 kbar.¹⁸⁶⁰

¹⁸⁶²The best results are obtained when the acyloxyboranes are made from a carboxylic acid and catecholborane (p. 1123): Collum, D.B.; Chen, S.; Ganem, B. *J. Org. Chem.* **1978**, 43, 4393.

1,1,1-trihalo ketones RCOCX_3 ,¹⁸⁶³ α -keto nitriles, acyl azides, and non-enolizable ketones (see the Haller–Bauer reaction **12-34**). A polymer-bound acyl derivative was converted to an amide using tributylvinyl tin, trifluoroacetic acid, AsPh_3 and a palladium catalyst.¹⁸⁶⁴ The source of amine in this reaction was the polymer itself, which was an amide resin. *N*-Acylsulfonamides react with primary amines to the amide (AcNHR).¹⁸⁶⁵ Aniline derivatives are converted to acetamides with *N*-acyloxymethylpyradazin-3-ones in dichloromethane.¹⁸⁶⁶ Carbonylation reactions can be used to prepare amides and related compounds. The reaction of a primary amine, an alkyl halide with CO_2 , in the presence of $\text{Cs}_2\text{CO}_3/\text{Bu}_4\text{NI}$, gave the corresponding carbamate.¹⁸⁶⁷

OS **III**, 394; **IV**, 6, 569; **V**, 160, 166; **VI**, 1004.

Imides can be prepared by the attack of amides or their salts on acyl halides, anhydrides, and carboxylic acids or esters.¹⁸⁶⁸ The best synthetic method for the preparation of acyclic imides is the reaction between an amide and an anhydride at 100°C catalyzed by H_2SO_4 .¹⁸⁶⁹ When acyl chlorides are treated with amides in a 2:1 molar ratio at low temperatures in the presence of pyridine, the products are *N,N*-diacylamides, $(\text{RCO})_2\text{N}$.¹⁸⁷⁰

This reaction is often used to prepare urea derivatives, an important example being the preparation of barbituric acid, **112**.¹⁸⁷¹

When the substrate is oxalyl chloride ($\text{ClCOCOC}\text{Cl}$) and the reagent an unsubstituted amide, an acyl isocyanate (RCONCO) is formed. The “normal” product ($\text{RCONH-COCOC}\text{Cl}$) does not form, or if it does, it rapidly loses CO and HCl .¹⁸⁷²

16-78 Acylation of Azides

The reaction of an aldehyde with sodium azide and $\text{Et}_4\text{I(OAc)}_2$ or polymer-bound PhI(OAc)_2 leads to an acyl azide.¹⁸⁷³

F. Attack by Halogen at an Acyl Carbon

16-79 Formation of Acyl Halides from Carboxylic Acids

Halo-de-hydroxylation

Halogenating agent = SOCl_2 , SOBr_2 , PCl_3 , POCl_3 , PBr_3 , and so on.

The same inorganic acid halides that convert alcohols to alkyl halides (**10-48**) also convert carboxylic acids to acyl halides.¹⁸⁷⁴ The reaction is the best and the most common method for the preparation of acyl chlorides. Bromides and iodides¹⁸⁷⁵ are also made in this manner, but much less often. Acyl bromides can be prepared with BBr_3 on alumina.¹⁸⁷⁶ Thionyl chloride¹⁸⁷⁷ is a good reagent, since the by-products are gases and the acyl halide is easily isolated, but PX_3 and PX_5 ($\text{X} = \text{Cl}$ or Br) are also commonly used.¹⁸⁷⁸ Hydrogen halides do not give the reaction. A particularly mild procedure, similar to one mentioned in **10-48**, involves reaction of the acid with Ph_3P in CCl_4 , whereupon acyl chlorides are produced without obtaining any acidic compound as a by-product.¹⁸⁷⁹ Acyl fluorides can be prepared by treatment of carboxylic acids with cyanuric fluoride.¹⁸⁸⁰ Acid salts

are also sometimes used as substrates. Acyl halides are also used as reagents in an exchange reaction:

which probably involves an anhydride intermediate. This is an equilibrium reaction that must be driven to the desired side.

A mild, and often superior reagent is oxalyl chloride (**113**) and oxalyl bromide, since oxalic acid decomposes to CO and CO₂, and the equilibrium is thus driven to the side of the other acyl halide.¹⁸⁸¹ These reagents are commonly the reagent of choice, particularly when sensitive functionality is present elsewhere in the molecule.

cuprous acetylide $R^2C\equiv CCu$ is the reagent.¹⁸⁹⁸ Organocopper reagents generated *in situ* from highly reactive copper, and containing such functional groups as cyano, chloro, and ester, react with acyl halides to give ketones.¹⁸⁹⁹

Many other organometallic reagents¹⁹⁰⁰ give good yields of ketones when treated with acyl halides because, as with R_2CuLi , R_2Cd , these compounds do not generally react with the ketone product. A particularly useful class of organometallic reagent are organocadmium reagents R_2Cd , prepared from Grignard reagents (12-22). In this case, R may be aryl or primary alkyl. In general, secondary and tertiary alkylcadmium reagents are not stable enough to be useful in this reaction.¹⁹⁰¹ An ester group may be present in either $R'COX$ or R_2Cd . Direct treatment of the acid chloride with an alkyl halide and cadmium metal leads to the ketone in some cases.¹⁹⁰² Organozinc compounds behave similarly to dialkylcadmium reagents, but are used less often.¹⁹⁰³ Organotin reagents R_4Sn react with acyl halides to give high yields of ketones, if a Pd complex is present.¹⁹⁰⁴ Organolead reagents R_4Pb behave similarly.¹⁹⁰⁵ Allylic halides and indium metal react with acyl chlorides to give the ketone.¹⁹⁰⁶ Various other groups, for example, nitrile, ester, and aldehyde can be present in the acyl halide without interference. Other reagents include organomanganese compounds¹⁹⁰⁷ (R can be primary, secondary, or tertiary alkyl, vinylic, alkynyl, or aryl), organozinc,¹⁹⁰⁸ and organothallium compounds (R can be primary alkyl or aryl).¹⁹⁰⁹ The reaction of an α -halo-ketone and an acyl chloride with SmI_2 leads to a β -diketone.¹⁹¹⁰ Initial reaction of an acyl chloride with palladium(0), followed by reaction with potassium acetate and then a trialkylborane gave a ketone.¹⁹¹¹ Arylboronic acids and acid chloride give the ketone in

the presence of a palladium catalyst.¹⁹¹² Similar reaction of acid chlorides, NaBPh₄, KF, and a palladium catalyst gave the aryl ketone.¹⁹¹³ Antimony alkynes such as Ph₂Sb–C≡C–Ph react with acid chloride in the presence of a palladium catalyst to give the conjugated alkynyl ketone.¹⁹¹⁴ Such conjugated ketones can also be prepared from an acyl halide, a terminal alkyne and a CuI catalyst¹⁹¹⁵ a palladium catalyst,¹⁹¹⁶ or with indium metal.¹⁹¹⁷ Terminal alkynes react with chloroformates and a palladium catalyst to give the corresponding propargyl ester.¹⁹¹⁸ Similar reaction of an alkyne with an acid chloride and a palladium–copper¹⁹¹⁹ or CuI catalyst,¹⁹²⁰ both with microwave irradiation, gave the alkynyl ketones.

When the organometallic compound is a Grignard reagent,¹⁹²¹ ketones are generally not obtained because the initially formed ketone reacts with a second molecule of RMgX to give the salt of a tertiary alcohol (**16-82**). Ketones *have* been prepared in this manner by the use of low temperatures, inverse addition (i.e., addition of the Grignard reagent to the acyl halide rather than the other way), excess acyl halide, and so on., but the yields are usually low, though high yields have been reported in THF at –78°C.¹⁹²² Pretreatment with a trialkylphosphine and then the Grignard reagent can lead to the ketone.¹⁹²³ Using CuBr¹⁹²⁴ or a nickel catalyst¹⁹²⁵ with the Grignard reagent can lead to the ketone. Some ketones are unreactive toward Grignard reagents for steric or other reasons; these can be prepared in this way.¹⁹²⁶ Other methods involve running the reaction in the presence of Me₃SiCl¹⁹²⁷ (which reacts with the initial adduct in the tetrahedral mechanism, p. 1254), and the use of a combined Grignard-lithium diethylamide reagent.¹⁹²⁸ Also, certain metallic halides, notably ferric and cuprous halides, are catalysts

that improve the yields of ketone at the expense of tertiary alcohol.¹⁹²⁹ For these catalysis, both free radical and ionic mechanisms have been proposed.¹⁹³⁰

Grignard reagents react with ethyl chloroformate to give carboxylic esters $\text{EtOCOCI} + \text{RMgX} \rightarrow \text{EtOCOR}$. Acyl halides can also be converted to ketones by treatment with $\text{Na}_2\text{Fe}(\text{CO})_4$ followed by $\text{R}'\text{X}$ (**10-76**).

16-82 The Conversion of Anhydrides, Carboxylic Esters, or Amides to Ketones With Organometallic Compounds¹⁹³¹

Dialkyl,hydroxy-de-alkoxy,oxo-tersubstitution; Alkyl-de-acyloxy- or de-amido substitution

When carboxylic esters are treated with Grignard reagents, addition to the carbonyl (**16-24**) generates a ketone. Under the reaction conditions, the initially formed ketones usually undergoes acyl substitution of R^2 for OR' (**16-81**), so that tertiary alcohols are formed in which two R groups are the same. Isolation of the ketone as the major product is possible in some cases, particularly when the reaction is done at low temperature¹⁹³² and when there is steric hindrance to the carbonyl in the first-formed ketone. Esters, RCO_2Me , react with $\text{Zn}(\text{BH}_4)_2/\text{EtMgBr}$ to give an alcohol, $\text{RCH}(\text{OH})\text{Et}$.¹⁹³³ Formates give secondary alcohols and carbonates give tertiary alcohols in which all three R groups are the same: $(\text{EtO})_2\text{C}=\text{O} + \text{RMgX} \rightarrow \text{R}_3\text{COMgX}$. Acyl halides and anhydrides behave similarly, though these substrates are employed less often.¹⁹³⁴ Many side reactions are possible, especially when the acid derivative or the Grignard reagent is branched: enolizations, reductions (not for esters, but for halides), condensations, and cleavages, but the most important is simple substitution (**16-81**), which in some cases can be made to predominate. When 1,4-dimagnesium compounds are used, carboxylic esters are converted to cyclopentanols.¹⁹³⁵ 1,5-Dimagnesium

compounds give cyclohexanols, but in lower yields.¹⁹³⁶

As is the case with acyl halides (**16-81**), anhydrides and carboxylic esters give tertiary alcohols (**16-82**) when treated with Grignard reagents. Low temperatures,¹⁹³⁷ the solvent HMPA,¹⁹³⁸ and inverse addition have been used to increase the yields of ketone.¹⁹³⁹ Amides give better yields of ketone at room temperature, but still not very high.¹⁹⁴⁰ Anhydrides can react with arylmagnesium halides at low temperature, and in the presence of (–)-sparteine, to give a keto acid with good enantioselectivity.¹⁹⁴¹ Organocadmium reagents are less successful with these substrates than with acyl halides (**16-81**). Esters of formic acid, dialkylformamides, and lithium or sodium formate¹⁹⁴² give good yields of aldehydes, when treated with Grignard reagents.

Alkyl lithium compounds have been used to give ketones from carboxylic esters. The reaction must be carried out in a high-boiling solvent, such as toluene, since reaction at lower temperatures gives tertiary alcohols.¹⁹⁴³ Alkyl lithium reagents also give good yields of carbonyl compounds with *N,N*-disubstituted amides.¹⁹⁴⁴ Dialkylformamides give aldehydes and other disubstituted amides give ketones and other acid derivatives have been used.¹⁹⁴⁵

Ketones can also be obtained by treatment of the lithium salt of a carboxylic acid with an alkyl lithium reagent (**16-28**). For an indirect way to convert carboxylic esters to ketones, see **16-82**. A similar reaction with hindered aryl carboxylic acids has been reported.¹⁹⁴⁶ Treatment of a β -amido acid with two equivalents of *n*-butyllithium, followed by reaction with an acid chloride leads to a β -keto amide.¹⁹⁴⁷ Carboxylic acids can be treated with 2-chloro-4,6-dimethoxy[1,3,5]-triazine and the RMgX/CuI to give ketones.¹⁹⁴⁸

Disubstituted formamides can give addition of 2 equivalents of Grignard reagent. The products of this reaction (called *Bouveault reaction*) are an aldehyde and a tertiary amine.¹⁹⁴⁹ The use of an amide other than a formamide

can give a ketone instead of an aldehyde, but yields are generally low. The addition of 2 equivalents of phenyllithium to a carbamate gave good yields of the ketone, however.¹⁹⁵⁰ When butyllithium reacted with an α -carbamoyl secondary amide $[\text{RCH}(\text{NHCO}_2\text{R}')\text{C}(=\text{O})\text{NR}_2]$ at -78°C , the amide reacted preferentially to give the α -carbamoyl ketone.¹⁹⁵¹ The reaction of *N*-(3-bromopropyl) lactams with *tert*-butyllithium gave cyclization to the bicyclic amino alcohol, and subsequent reduction with LiAlH_4 (**19-64**) gave the bicyclic amine.¹⁹⁵² Ketones can also be prepared by treatment of thioamides with organolithium compounds (alkyl or aryl).¹⁹⁵³ Cerium reagents, such as MeCeCl_2 , also add two R groups to an amide.¹⁹⁵⁴ More commonly, an organolithium reagent is treated with CeCl_3 to generate the organocerium reagent *in situ*.¹⁹⁵⁵ It has proven possible to add two different R groups by sequential addition of two Grignard reagents.¹⁹⁵⁶ Diketones have also been produced by using the bis(imidazole) derivative of oxalic acid.¹⁹⁵⁷ Alternatively, if R' contains an α hydrogen, the product may be an enamine, and enamines have been synthesized in good yields by this method.¹⁹⁵⁸ When an amide having a *gem*-dibromocyclopropyl unit elsewhere in the molecule was treated

with methyllithium, Li–Br exchange was accompanied by intramolecular acyl addition to the amide carbonyl, giving a bicyclic amino alcohol.¹⁹⁵⁹

N-Methoxy-*N*-methyl amides, such as, **114**, are referred to as a **Weinreb amide**.¹⁹⁶⁰ When a Weinreb amide reacts with a Grignard reagent or an organolithium reagent,¹⁹⁶¹ the product is the ketone. The reaction of **56** with 3-butenylmagnesium bromide to give ketone **115** is a typical example.¹⁹⁶² Aryloxy carbamates with a Weinreb amide unit, ArO₂C–NMe(OMe), react with RMgBr and then R'Li to give an unsymmetrical ketone, RC(=O)R'.¹⁹⁶³ Intramolecular displacement of a Weinreb amide by an organolithium reagent generated *in situ* from an iodide precursor leads to cyclic ketones.¹⁹⁶⁴ Reaction with vinylmagnesium bromide led to a β-*N*-methoxy-*N*-methylamino ketone, presumably by initial formation of the conjugated ketone followed by Michael addition (**15-24**) of the liberated amine.¹⁹⁶⁵ An interesting extension of this acyl substitution reaction coupled vinylmagnesium bromide with a Weinreb amide to give a conjugated ketone, which reacted with a secondary amine in a second step (see **15-31**) to give a β-amino ketone.¹⁹⁶⁶

By the use of the compound *N*-methoxy-*N,N',N'*-trimethylurea, it is possible to add two R groups as RLi, the same or different, to a CO group.¹⁹⁶⁷

N,N-Disubstituted amides can be converted to alkynyl ketones by treatment with alkynylboranes: RCONR₂² + (R'C≡C)₃B → RCOC≡CR'.¹⁹⁶⁸ Lactams react with triallylborane to give cyclic 2,2-diallyl amines after treatment with methanol, and then aqueous hydroxide.¹⁹⁶⁹ Triallylborane reacts with the carbonyl group of lactams, and after treatment with methanol and then aqueous NaOH gives the

via intramolecular addition of the organometallic intermediate to one carbonyl.¹⁹⁸⁸ The reaction of alkylzinc halides and thioesters leads to ketones in the presence of 1.5% Pd/C,¹⁹⁸⁹ in what has been called *Fukuyama coupling*.¹⁹⁹⁰

Carboxylic esters can be converted to their homologs (RCOOEt → RCH₂COOEt) by treatment with Br₂CHLi followed by BuLi at -90°C. The ynoate RC≡COLi is an intermediate.¹⁹⁹¹ If the ynoate is treated with 1,3-cyclohexadiene, followed by NaBH₄, the product is the alcohol RCH₂CH₂OH.¹⁹⁹²

Note that acyl benzotriazoles react with β-keto esters to give diketones via acyl substitution.¹⁹⁹³ Acyl cyanides, RC(=O)CN, react with allylic bromides and indium metal to give the corresponding ketone.¹⁹⁹⁴ Coupling an acid chloride and a silyl amide, R₃SiC(=O)NR'₂, leads to an α-keto amide.¹⁹⁹⁵ Acyl benzotriazoles have been coupled with SmI₂ to give the 1,2-diketone.¹⁹⁹⁶ α-Cyanoketone (acyl nitriles) were coupled with YbI₂ in a similar manner.¹⁹⁹⁷ α-Keto phosphonate esters undergo radical acyl substitution to give cyclic ketones under photochemical conditions.¹⁹⁹⁸

Silyl esters are converted to the enolate anion upon treatment with *n*-butyllithium, and subsequent addition of an aldehyde followed by saponification leads to the β-hydroxy acid.¹⁹⁹⁹

Vinyl organometallic reagents can be added to acyl derivatives. Reaction of an alkyne with Cp₂ZrEt₂ generates the vinyl zirconium reagent, which react with ethyl chloroformate to give an α,β-unsaturated ester.²⁰⁰⁰

Acyl halides can be coupled with pyrophoric lead to give symmetrical α -diketones in a Wurtz-type reaction.²⁰⁰¹ The reaction has been performed with $R = \text{Me}$ and Ph . Samarium iodide SmI_2 ²⁰⁰² gives the same reaction. Benzoyl chloride was coupled to give benzil by subjecting it to ultrasound in the presence of Li wire:

Unsymmetrical α -diketones, RCOCOR' , have been prepared by treatment of an acyl halide RCOCl with an acyltin reagent ($\text{R}'\text{COSnBu}_3$), with a palladium complex catalyst.²⁰⁰⁴

16-84 Acylation at a Carbon Bearing an Active Hydrogen

Bis(ethoxycarbonyl)methyl-de-halogenation, and so on

This reaction is similar to **10-67**, but there are fewer examples.²⁰⁰⁵ Either Z or Z' may be any of the groups listed in **10-67**.²⁰⁰⁶ Anhydrides react similarly but are used less often. The product contains three Z groups, since RCO is a Z group. One or two of these can be cleaved (**12-40**, **12-43**). In this way, a compound $\text{ZCH}_2\text{Z}'$ can be converted to ZCH_2Z^2 or an acyl halide (RCOCl) to a methyl ketone (RCOCH_3). *O*-Acylation is sometimes a side reaction.²⁰⁰⁷ When thallium(I) salts of $\text{ZCH}_2\text{Z}'$ are used, it is possible to achieve regioselective acylation at either the C or the O position. For example, treatment of the thallium(I) salt of $\text{MeCOCH}_2\text{COME}$ with acetyl chloride at -78°C gave $>90\%$ *O*-acylation, while acetyl fluoride at room temperature gave $>95\%$ *C*-acylation.²⁰⁰⁸ The use of an alkyl chloroformate gives triesters.²⁰⁰⁹

The application of this reaction to simple ketones²⁰¹⁰ (in parallel with **10-68**) requires a strong base, such as NaNH_2 or Ph_3CNa , and is often complicated by

O-acylation, which in many cases becomes the principal pathway because acylation at the oxygen is usually much faster. It is possible to increase the proportion of *C*-acylated product by employing an excess (2–3 equivalents) of enolate anion (and adding the substrate to this, rather than vice versa), by the use of a relatively non-polar solvent and a metal ion (e.g., Mg^{2+}), which is tightly associated with the enolate oxygen atom, by the use of an acyl halide rather than an anhydride,²⁰¹¹ and by working at low temperatures.²⁰¹² In cases where the use of an excess of enolate anion results in *C*-acylation, it is because *O*-acylation takes place first, and the *O*-acylated product (an enol ester) is then *C*-acylated. Simple ketones can also be acylated by treatment of their silyl enol ethers with an acyl chloride in the presence of ZnCl_2 or SbCl_3 .²⁰¹³ Ketones can be acylated by anhydrides to give β -diketones, with BF_3 as catalyst.²⁰¹⁴ Simple esters RCH_2COOEt can be acylated at the α carbon (at -78°C) if a strong base such as lithium *N*-isopropylcyclohexylamide is used to remove the proton.²⁰¹⁵

16-85 Acylation of Carboxylic Esters by Carboxylic Esters: The Claisen and Dieckmann Condensations

Alkoxycarbonylalkyl-de-alkoxy-substitution

When carboxylic esters containing an α hydrogen are treated with a strong base, such as sodium ethoxide, a condensation occurs to give a β -keto ester via an ester enolate anion.²⁰¹⁶ This reaction is called the *Claisen condensation*. When it is carried out with a mixture of two different esters, each of which possesses an α hydrogen (this reaction is called a mixed Claisen or a crossed Claisen condensation), a mixture of all four products is generally obtained and the reaction is seldom useful synthetically.²⁰¹⁷ However, if only one of the esters has an

²⁰¹⁴For a review, see Hauser, C.R.; Swamer, F.W.; Adams, J.T. *Org. React.* 1954, 8, 59, 98–106.

²⁰¹⁵For example, see Rathke, M.W.; Deitch, J. *Tetrahedron Lett.* 1971, 2953; Logue, M.W. *J. Org. Chem.* 1974, 39, 3455; Couffignal, R.; Moreau, J. *J. Organomet. Chem.* 1977, 127, C65; Ohta, S.; Shimabayashi, A.; Hayakawa, S.; Sumino, M.; Okamoto, M. *Synthesis* 1985, 45; Hayden, W.; Pucher, R.; Griengl, H. *Monatsh. Chem.* 1987, 118, 415.

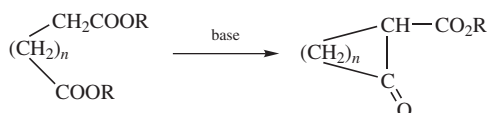

²⁰¹⁶For a study of ester and amide enolate stabilization, see Rablen, P.R.; Bentrup, K.L.H. *J. Am. Chem. Soc.* 2003, 125, 2142.

²⁰¹⁷For a method of allowing certain crossed-Claisen reactions to proceed with good yields, see Tanabe, Y. *Bull. Chem. Soc. Jpn.* 1989, 62, 1917.

α hydrogen, the mixed reaction is frequently satisfactory. Among esters lacking α hydrogens (hence acting as the substrate ester) that are commonly used in this way are esters of aromatic acids, and ethyl carbonate and ethyl oxalate. When the ester enolate reacts with ethyl carbonate, the product is a malonic ester, and reaction with ethyl formate introduces a formyl group. Claisen condensation of phenyl esters with ZrCl_4 and diisopropylethylamine (Hünigs base) give the corresponding keto ester.²⁰¹⁸

As with ketone enolate anions (see **16-34**), the use of amide bases under kinetic control conditions (strong base with a weak conjugate acid, aprotic solvents, low temperatures), allows the mixed Claisen condensation to proceed. Self-condensation of the lithium enolate with the parent ester is a problem when LDA is used as a base,²⁰¹⁹ but this is minimized with LICA (lithium isopropylcyclohexyl amide).²⁰²⁰ Note that solvent-free Claisen condensation reactions have been reported.²⁰²¹

When the two ester groups involved in the condensation are in the same molecule, the product is a cyclic β -keto ester and the reaction is called the *Dieckmann condensation*.²⁰²²

The Dieckmann condensation is most successful for the formation of five-, six-, and seven-membered rings. Yields for rings of 9–12 members are very low or nonexistent; larger rings can be closed with high-dilution techniques. Reactions in which large rings are to be closed are generally assisted by high dilution, since one end of the molecule has a better chance of finding the other end than of finding another molecule. A solvent-free Dieckmann condensation has been reported on solid potassium *tert*-butoxide.²⁰²³ Dieckmann condensation of unsymmetrical substrates can be made regioselective (unidirectional) by the use of solid-phase supports.²⁰²⁴

The mechanism of the Claisen and Dieckmann reactions is the ordinary tetrahedral mechanism,²⁰²⁵ with one molecule of ester being converted to a nucleophile by

²⁰²²For a review, see Schaefer, J.P.; Bloomfield, J.J. *Org. React.* **1967**, *15*, 1.

²⁰²³Toda, F.; Suzuki, T.; Higa, S. *J. Chem. Soc. Perkin Trans. 1* **1998**, 3521.

²⁰²⁴Crowley, J.J.; Rapoport, H. *J. Org. Chem.* **1980**, *45*, 3215. For another method, see Yamada, Y.; Ishii, T.; Kimura, M.; Hosaka, K. *Tetrahedron Lett.* **1981**, *22*, 1353.

²⁰²⁵There is evidence that, at least in some cases, an SET mechanism is involved: Ashby, E.C.; Park, W. *Tetrahedron Lett.* **1983**, 1667. The transition structures have also been examined by Nishimura, T.; Sunagawa, M.; Okajima, T.; Fukazawa, Y. *Tetrahedron Lett.* **1997**, *38*, 7063.

the base and the other serving as the substrate.

This reaction illustrates the striking difference in behavior between carboxylic esters on the one hand and aldehydes and ketones on the other. When a carbanion, such as an enolate anion, is added to the carbonyl group of an aldehyde or ketone (**16-38**), the H or R is not lost, since these groups are much poorer leaving groups than OR. Instead the intermediate similar to **116** adds a proton at the oxygen to give a hydroxy compound.

In contrast to **10-67** ordinary esters react quite well, that is, two Z groups are not needed. A lower degree of acidity is satisfactory because it is not necessary to convert the attacking ester entirely to its ion. Step 1 is an equilibrium that lies well to the left. Nevertheless, the small amount of enolate anion formed is sufficient to attack the readily approachable ester substrate. All the steps are equilibria. The reaction proceeds because the product is converted to its conjugate base by the base present (i.e., a β -keto ester is a stronger acid than an alcohol):

The use of a stronger base, such as NaNH_2 , NaH , or KH ,²⁰²⁶ often increases the yield. For some esters stronger bases *must* be used, since sodium ethoxide is ineffective. Among these are esters of the type $\text{R}_2\text{CHCOOEt}$, the products of which ($\text{R}_2\text{CHCOCR}_2\text{COOEt}$) lack an acidic hydrogen, so that they cannot be converted to enolate anions by sodium ethoxide.²⁰²⁷ The Dieckmann condensation has also been done using $\text{TiCl}_3/\text{NBU}_3$ with a TMSOTf catalyst.²⁰²⁸ A Dieckmann-like condensation was reported where an α,ω -dicarboxylic acid was heated to 450°C on graphite, with microwave irradiation, to give the cyclic ketone.²⁰²⁹

16-86 Acylation of Ketones and Nitriles by Carboxylic Esters

α -Acylalkyl-de-alkoxy-substitution

Carboxylic esters can be treated with ketones to give β -diketones. The reaction is so similar that it is sometimes also called the Claisen reaction, though this usage may be confusing. A strong base, such as sodium amide or sodium hydride, is required. Yields can be increased by the catalytic addition of crown ethers.²⁰³⁰ Esters of formic acid (R = H) give β -keto aldehydes and ethyl carbonate gives β -keto esters. β -Keto esters can also be obtained by treating the lithium enolates of ketones with methyl cyanofornate MeOCOCN ²⁰³¹ (in this case CN is the leaving group) and by treating ketones with KH and diethyl dicarbonate, $(\text{EtOCO})_2\text{O}$.²⁰³²

In the case of unsymmetrical ketones, the attack usually comes from the less highly substituted side, so that CH_3 is more reactive than RCH_2 , and the R_2CH group rarely attacks. This reaction has been used to effect cyclization, especially to prepare five- and six-membered rings. Nitriles are frequently used instead of ketones, the products being β -keto nitriles.

Other nucleophilic carbon reagents, such as acetylide ions, and ions derived from α -methylpyridines have also been used. A particularly useful nucleophile is the methylsulfinyl carbanion, $\text{CH}_3\text{SOCH}_2^-$,²⁰³³ the conjugate base of DMSO, since the β -keto sulfoxide produced can easily be reduced to a methyl ketone (p. 624). The methylsulfonyl carbanion ($\text{CH}_3\text{SO}_2\text{CH}_2^-$), the conjugate base of dimethyl sulfone, behaves similarly,²⁰³⁴ and the product can be similarly reduced. Certain carboxylic esters, acyl halides, and DMF will acylate 1,3-dithianes²⁰³⁵ (see 10-71) to give, after oxidative hydrolysis with NBS or NCS, α -keto aldehydes or

²⁰³⁵Corey, E.J.; Seebach, D. *J. Org. Chem.* **1975**, 40, 231

α -diketones,²⁵⁴ for example,

As in **10-67**, a ketone attacks with its second most acidic position if 2 equivalents of base are used. Thus, β -diketones have been converted to 1,3,5-triketones.²⁰³⁶

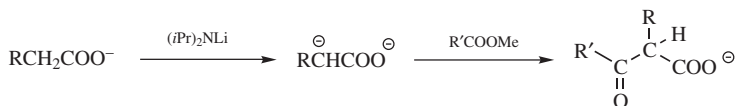

Side reactions are condensation of the ketone with itself (**16-34**), of the ester with itself, and of the ketone with the ester, but with the ester supplying the α position (**16-36**). The mechanism is the same as in **16-85**.²⁰³⁷

OS **I**, 238; **II**, 126, 200, 287, 487, 531; **III**, 17, 251, 291, 387, 829; **IV**, 174, 210, 461, 536; **V**, 187, 198, 439, 567, 718, 747; **VI**, 774; **VII**, 351.

16-87 Acylation of Carboxylic Acid Salts

α -Carboxyalkyl-de-alkoxy-substitution

We have previously seen (**10-70**) that dianions of carboxylic acids can be alkylated in the α position. These ions can also be acylated on treatment with a carboxylic ester²⁰³⁸ to give salts of β -keto acids. As in **10-70**, the carboxylic acid can be of the form RCH_2COOH or $RR^2CHCOOH$. Since β -keto acids are so easily converted to ketones (**12-40**), this is also a method for the preparation of ketones $R'COCH_2R$ and $R'COCHRR^2$, where R' can be primary, secondary, or tertiary alkyl, or aryl. If the ester is ethyl formate, an α -formyl carboxylate salt ($R' = H$) is formed, which on acidification spontaneously decarboxylates into an aldehyde.²⁰³⁹ This method accomplishes the conversion $RCH_2COOH \rightarrow RCH_2CHO$, and is an alternative to the reduction methods discussed in **19-39**. When the carboxylic acid is of the form $RR''CHCOOH$, better yields are obtained by acylating with acyl halides rather than esters.²⁰⁴⁰

16-88 Preparation of Acyl Cyanides**Cyano-de-halogenation**

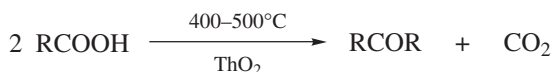

Acyl cyanides²⁰⁴¹ can be prepared by treatment of acyl halides with copper cyanide. The mechanism could be free-radical or nucleophilic substitution. The reaction has also been accomplished with thallium(I) cyanide,²⁰⁴² with Me_3SiCN and an SnCl_4 catalyst,²⁰⁴³ and with Bu_3SnCN ,²⁰⁴⁴ but these reagents are successful only when R = aryl or tertiary alkyl. KCN has also been used, along with ultrasound,²⁰⁴⁵ as has NaCN with phase-transfer catalysts.²⁰⁴⁶

OS III, 119.

16-89 Preparation of Diazo Ketones**Diazomethyl-de-halogenation**

The reaction between acyl halides and diazomethane is of wide scope and is the best way to prepare diazo ketones.²⁰⁴⁷ Diazomethane must be present in excess or the HX produced will react with the diazo ketone (10-52). This reaction is the first step of the *Arndt-Eistert synthesis* (18-8). Diazo ketones can also be prepared directly from a carboxylic acid and diazomethane or diazoethane in the presence of DCC.²⁰⁴⁸

Carboxylic acids can be converted to symmetrical ketones by pyrolysis in the presence of thorium oxide. In a mixed reaction, formic acid and another acid heated over thorium oxide give aldehydes. Mixed alkyl aryl ketones have been prepared by heating mixtures of ferrous salts.²⁰⁵⁰ When the R group is large, the methyl ester rather than the acid can be decarbomethoxylated over thorium oxide to give the symmetrical ketone.

The reaction has been performed on dicarboxylic acids, whereupon cyclic ketones are obtained:

This process, called *Ruzicka cyclization*, is good for the preparation of rings of six and seven members and, with lower yields, of C₈ and C₁₀-C₃₀ cyclic ketones.²⁰⁵¹

Not much work has been done on the mechanism of this reaction. However, a free-radical mechanism has been suggested on the basis of a thorough study of all the side products.²⁰⁵²

REACTIONS IN WHICH CARBON ADDS TO THE HETEROATOM

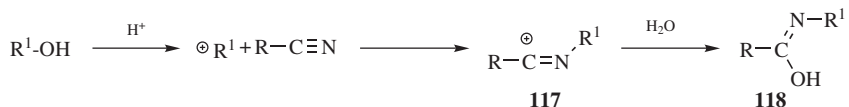

A. Oxygen Adding to the Carbon

16-91 The Ritter Reaction

N-Hydro,*N*-alkyl-*C*-oxo-biaddition

Alcohols can be added to nitriles in an entirely different manner from that of reaction 16-9. In this reaction, the alcohol is converted by a strong acid to a carbocation, which is attacked by the nucleophilic nitrogen atom to give 117. Subsequent addition of water to the electrophilic carbon atom leads to the enol form of the amide (see 118), which tautomerizes (p. 98) to the *N*-alkyl amide.

²⁰⁵⁰Granito, C.; Schultz, H.P. *J. Org. Chem.* **1963**, 28, 879.

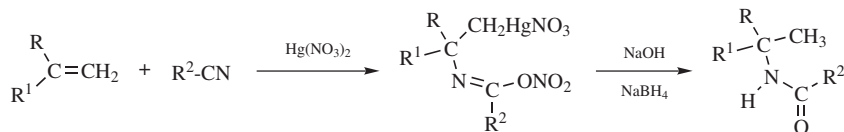

²⁰⁵¹See, for example, Ruzicka, L.; Stoll, M.; Schinz, H. *Helv. Chim. Acta* **1926**, 9, 249; **1928**, 11, 1174; Ruzicka, L.; Brugger, W.; Seidel, C.F.; Schinz, H. *Helv. Chim. Acta* **1928**, 11, 496.

²⁰⁵²Hites, R.A.; Biemann, K. *J. Am. Chem. Soc.* **1972**, 94, 5772. See also, Bouchoule, C.; Blanchard, M.; Thomassin, R. *Bull. Soc. Chim. Fr.* **1973**, 1773.

Only alcohols that give rise to fairly stable carbocations react (secondary, tertiary, benzylic, etc.); non-benzylic primary alcohols do not give the reaction. The carbocation need not be generated from an alcohol, but may come from protonation of an alkene or from other sources. In any case, the reaction is called the *Ritter reaction*.²⁰⁵³ Lewis acids, such as $\text{Mg}(\text{HSO}_4)_2$, have been used to promote the reaction.²⁰⁵⁴ Highly sterically hindered nitriles have been converted to *N*-methyl amides by heating with methanol and sulfuric acid.²⁰⁵⁵ HCN also gives the reaction, the product being a formamide. Trimethylsilyl cyanide has also been used.²⁰⁵⁶

Since the amides (especially the formamides) are easily cleaved under hydrolysis conditions to amines, the Ritter reaction provides a method for achieving the conversions $\text{R}'\text{OH} \rightarrow \text{R}'\text{NH}_2$ (see **10-32**) and alkene $\rightarrow \text{R}'\text{NH}_2$ (see **15-8**) in those cases where R' can form a relatively stable carbocation. The reaction is especially useful for the preparation of tertiary alkyl amines because there are few alternate ways of preparing these compounds. The reaction can be extended to primary alcohols by treatment with triflic anhydride²⁰⁵⁷ or $\text{Ph}_2\text{CCl}^+ \text{SbCl}_6^-$ or a similar salt²⁰⁵⁸ in the presence of the nitrile.

Alkenes of the form $\text{RCH}=\text{CHR}'$ and $\text{RR}'\text{C}=\text{CH}_2$ add to nitriles in the presence of mercuric nitrate to give, after treatment with NaBH_4 , the same amides that would be obtained by the Ritter reaction.²⁰⁵⁹ This method has the advantage of avoiding strong acids.

Benzylic compounds, such as ethylbenzene, react with alkyl nitriles, ceric ammonium nitrate, and a catalytic amount of *N*-hydroxysuccinimide to give the Ritter product, the amide.²⁰⁶⁰

The Ritter reaction can be applied to cyanamides RNHCN to give ureas $\text{RNHCONHR}'$.²⁰⁶¹

16-92 The Addition of Aldehydes to Aldehydes

When catalyzed by acids, low-molecular-weight aldehydes add to each other to give cyclic acetals, the most common product being the trimer.²⁰⁶² The cyclic trimer of formaldehyde is called *trioxane*,²⁰⁶³ and that of acetaldehyde is known as *paraldehyde*. Under certain conditions, it is possible to get tetramers²⁰⁶⁴ or dimers. Aldehydes can also polymerize to linear polymers, but here a small amount of water is required to form hemiacetal groups at the ends of the chains. The linear polymer formed from formaldehyde is called *paraformaldehyde*. Since trimers and polymers of aldehydes are acetals, they are stable to bases, but can be hydrolyzed by acids. Because formaldehyde and acetaldehyde have low boiling points, it is often convenient to use them in the form of their trimers or polymers.

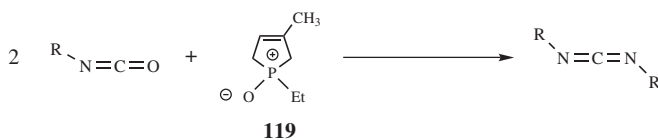

Aryl aldehydes condense with aliphatic aldehydes in the presence of benzoylformate decarboxylase and thiamin diphosphate to give an α -hydroxy ketone with good enantioselectivity.²⁰⁶⁵

A slightly related reaction involves nitriles, which can be trimerized with various acids, bases, or other catalysts to give triazines (see OS III, 71).²⁰⁶⁶ Here HCl is most often used. Most nitriles with an α hydrogen do not give the reaction.

yields.²⁰⁶⁸ The mechanism does not simply involve the addition of one molecule of isocyanate to another, since the kinetics are first order in isocyanate and first order in catalyst. The following mechanism has been proposed (the catalyst is here represented as $R_3P^+-O^-$):²⁰⁶⁹

According to this mechanism, one molecule of isocyanate undergoes addition to $C=O$, and the other addition to $C=N$. Evidence is that ¹⁸O labeling experiments have shown that each molecule of CO₂ produced contains one oxygen atom derived from the isocyanate and one from **119**,²⁰⁷⁰ precisely what is predicted by this mechanism. Certain other catalysts are also effective.²⁰⁷¹ High-load, soluble oligomeric carbodiimides have been prepared.²⁰⁷²

OS V, 501.

16-94 The Conversion of Carboxylic Acid Salts to Nitriles

Nitrilo-de-oxido,oxo-tersubstitution

Salts of aliphatic or aromatic carboxylic acids can be converted to the corresponding nitriles by heating with BrCN or ClCN. Despite appearances, this is not a substitution reaction. When $R^{14}COO^-$ was used, the label appeared in the nitrile, not in the CO₂,²⁰⁷³ and optical activity in R was retained.²⁰⁷⁴ The acyl isocyanate $RCN=C=O$ could be isolated from the reaction mixture; hence the

following mechanism was proposed:²⁰⁷³

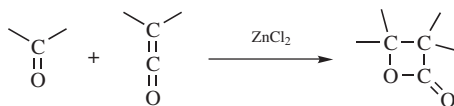

C. Carbon Adding to the Carbon.

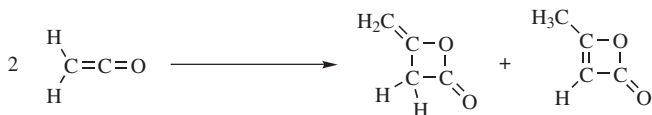

The reactions in this group are cycloadditions.

16-95 The Formation of β -Lactones and Oxetanes

(2+2)OC,CC-cyclo-[oxoethylene]-1/2/addition

Aldehydes, ketones, and quinones react with ketenes to give β -lactones,²⁰⁷⁵ diphenylketene being used most often.²⁰⁷⁶ The reaction is catalyzed by Lewis acids, and without them most ketenes do not give adducts because the adducts decompose at the high temperatures necessary when no catalyst is used. When ketene was added to chloral (Cl₃CCHO) in the presence of the chiral catalyst (+)-quinidine, one enantiomer of the β -lactone was produced with excellent enantioselectivity.²⁰⁷⁷ The use of a chiral aluminum catalyst also led to β -lactones with good syn selectivity and good enantioselectivity.²⁰⁷⁸ Other di- and trihalo aldehydes and ketones also give the reaction enantioselectively, with somewhat lower enantioselectivity.²⁰⁷⁹ Ketene adds to another molecule of itself:

This dimerization is so rapid that ketene does not form β -lactones with aldehydes or ketones, except at low temperatures. Other ketenes dimerize more slowly. In

these cases, the major dimerization product is not the β -lactone, but a cyclobutane-dione (see **15-63**). However, the proportion of ketene that dimerizes to β -lactone can be increased by the addition of catalysts, such as triethylamine or triethyl phosphite.²⁰⁸⁰ Ketene acetals $R_2C=C(OR')_2$ add to aldehydes and ketones in the presence of $ZnCl_2$ to give the corresponding oxetanes.²⁰⁸¹

Ordinary aldehydes and ketones can add to alkenes, under the influence of *UV* light, to give oxetanes. Quinones also react to give spirocyclic oxetanes.²⁰⁸² This reaction, called the *Paterno-Büchi reaction*,²⁰⁸³ is similar to the photochemical dimerization of alkenes discussed at **15-63**. In general, the mechanism consists of the addition of an excited state of the carbonyl compound to the ground state of the alkene. Both singlet (S_1)²⁰⁸⁴ and n,π^* triplet²⁰⁸⁵ states have been shown to add to alkenes to give oxetanes. A diradical intermediate²⁰⁸⁶

has been detected by spectroscopic methods.²⁰⁸⁷ Yields in the *Paterno-Büchi reaction* are variable, ranging from very low to fairly high (90%). The reaction can be

highly diastereoselective,²⁰⁸⁸ and allylic alcohols were shown to react with aldehydes to give an oxetane with syn selectivity.²⁰⁸⁹ There are several side reactions. When the reaction proceeds through a triplet state, it can in general be successful only when the alkene possesses a triplet energy comparable to, or higher than, the carbonyl compound; otherwise energy transfer from the excited carbonyl group to the ground-state alkene can take place (triplet-triplet photosensitization, see p. 340).²⁰⁹⁰ In most cases, quinones react normally with alkenes, giving oxetane products, but other α,β -unsaturated ketones usually give preferential cyclobutane formation (**15-63**). Aldehydes and ketones also add photochemically to allenes to give the corresponding alkylideneoxetanes and dioxaspiro compounds.²⁰⁹¹ Aldehydes add to silyl enol ethers.²⁰⁹² An intramolecular reaction of ketones was reported to give a bicyclic oxetane via photolysis on the solid state.²⁰⁹³

$\text{RCH}=\text{C}=\text{O}$, except when these are generated *in situ* by decomposition of a diazo ketone (the Wolff rearrangement, **18-8**) in the presence of the imine. It has been done with ketene, but the more usual course with this reagent is an addition to the enamine tautomer of the substrate. Thioketenes²⁰⁹⁵ ($\text{R}_2\text{C}=\text{C}=\text{S}$) give β -thio-lactams.²⁰⁹⁶ Imines also form β -lactams when treated with (1) zinc (or another metal²⁰⁹⁷) and an α -bromo ester (Reformatsky conditions, **16-28**),²⁰⁹⁸ or (2) the chromium carbene complexes $(\text{CO})_5\text{Cr}=\text{C}(\text{Me})\text{OMe}$.²⁰⁹⁹ The latter method has been used to prepare optically active β -lactams.²¹⁰⁰ Ketenes have also been added to certain hydrazones (e.g., $\text{PhCH}=\text{NNMe}_2$) to give *N*-amino β -lactams.²¹⁰¹ A polymer-bound pyridinium salt facilitates β -lactam formation from carboxylic acids and imines.²¹⁰²

N-Tosyl imines react with ketenes, Proton Sponge (p. 365) and a chiral amine to give the *N*-tosyl β -lactam with good enantioselectivity.²¹⁰³ A chiral ferrocenyl catalyst also gives good enantioselectivity,²¹⁰⁴ and chiral ammonium salts have been used as catalysts.²¹⁰⁵ A catalytic amount of benzoyl quinine gives β -lactams with good enantioselectivity.²¹⁰⁶ An intramolecular version of this ketene-imine reaction is known.²¹⁰⁷

Like the similar cycloaddition of ketenes to alkenes (**15-63**), most of these reactions probably take place by the diionic mechanism *c* (p. 1224).²¹⁰⁸ β -Lactams have also been prepared in the opposite manner: by the addition of enamines to isocyanates:²¹⁰⁹

The reactive compound chlorosulfonyl isocyanate (ClSO₂NCO)²¹¹⁰ forms β-lactams even with unactivated alkenes,²¹¹¹ as well as with imines,²¹¹² allenes,²¹¹³ conjugated dienes,²¹¹⁴ and cyclopropenes.²¹¹⁵ With microwave irradiation, alkyl isocyanates also react.²¹¹⁶

α-Diazo ketones react with imines and microwave irradiation to give β-lactams.²¹¹⁷ Allylic phosphonate esters react with imines, in the presence of a palladium catalyst, to give β-lactams.²¹¹⁸ Alkynyl reagents, such as BuC≡CO–Li⁺, react with imines to form β-lactams.²¹¹⁹ Imines and benzylic halides react to give β-lactams in the presence of CO and a palladium catalyst.²¹²⁰ Conjugated amides react with NBS and 20% sodium acetate to give an α-bromo β-lactam.²¹²¹ A different approach to β-lactams heated aziridines with CO and a cobalt catalyst.²¹²² Aziridines also react with CO and a dendrimer catalyst to go a β-lactam.²¹²³

OS V, 673; VIII, 3, 216.

ADDITION TO ISOCYANIDES²¹²⁴

Addition to R–⁺N≡C[–] is not a matter of a species with an electron pair adding to one atom and a species without a pair adding to the other, as is addition to the other types of double and triple bonds in this chapter and Chapter 15. In these additions, the electrophile and the nucleophile *both add to the carbon*. No species

²¹¹⁰For reviews of this compound, see Kamal, A.; Sattur, P.B. *Heterocycles* **1987**, *26*, 1051; Szabo, W.A. *Aldrichimica Acta* **1977**, *10*, 23; Rasmussen, J.K.; Hassner, A. *Chem. Rev.* **1976**, *76*, 389; Graf, R. *Angew. Chem. Int. Ed.* **1968**, *7*, 172.

add to the

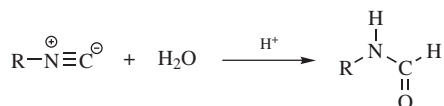

nitrogen, which, however, loses its positive charge by obtaining as an unshared pair one of the triple-bond pairs of electrons to give **120**. In most of the reactions considered below, **120** undergoes a further reaction, so the product is of the form.

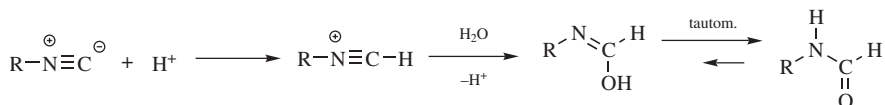

16-97 The Addition of Water to Isocyanides

1/N,2/C-Dihydro-2/C-oxo-biaddition

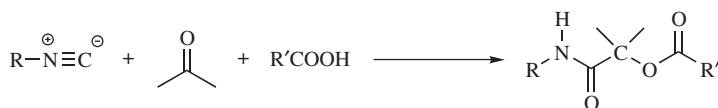

Formamides can be prepared by the acid-catalyzed addition of water to isocyanides. The mechanism is probably²¹²⁵

The reaction has also been carried out under alkaline conditions, with hydroxide in aqueous dioxane.²¹²⁶ The mechanism here involves nucleophilic attack by hydroxide at the carbon atom. An intramolecular addition of an alkyne (in an ortho alkyne phenyl isonitrile) to the carbon of an isonitrile occurred with heating in methanol to give quinoline derivatives.²¹²⁷

16-98 The Passerini and Ugi Reactions²¹²⁸

1/N-Hydro-2/C-(α -acyloxyalkyl),2/C-oxo-biaddition

When an isocyanide is treated with a carboxylic acid and an aldehyde or ketone, an α -acyloxy amide is prepared. This is called the *Passerini reaction*. A SiCl_4 -mediated reaction in the presence of a chiral bis-phosphoramidate gives an α -hydroxy amide with good enantioselectivity.²¹²⁹ The following mechanism has been postulated for the basic reaction:²¹³⁰

If ammonia or an amine is also added to the mixture (in which case the reaction is known as the *Ugi reaction*, or the *Ugi four-component condensation*, abbreviated 4 CC), the product is the corresponding bis(amide)

(from NH_3) or

(from a primary amine R^2NH_2).

Repetitive Ugi reactions are known.²¹³¹ This product probably arises from a reaction between the carboxylic acid, the isocyanide, and the *imine* formed from the aldehyde or ketone and ammonia or the primary amine. The use of an *N*-protected amino acid²¹³² or peptide as the carboxylic acid component and/or the use of an isocyanide containing a *C*-protected carboxyl group allows the reaction to be used for peptide synthesis.²¹³³

16-99 The Formation of Metalated Aldimines

1/1/Lithio-alkyl-addition

Isocyanides that do not contain an α hydrogen react with alkyllithium compounds,²¹³⁴ as well as with Grignard reagents, to give lithium (or magnesium) aldimines.²¹³⁵ These metalated aldimines are versatile nucleophiles and react with various substrates as follows:

The reaction therefore constitutes a method for converting an organometallic compound $\text{R}'\text{M}$ to an aldehyde $\text{R}'\text{CHO}$ (see also, **12-33**), an α -keto acid,²¹³⁶ a ketone $\text{R}'\text{COR}$ (see also, **12-33**), an α -hydroxy ketone, or a β -hydroxy ketone. In each case, the $\text{C}=\text{N}$ bond is hydrolyzed to a $\text{C}=\text{O}$ bond (**16-2**).

In a related reaction, isocyanides can be converted to aromatic aldimines by treatment with an iron complex followed by irradiation in benzene solution: $\text{RNC} + \text{C}_6\text{H}_6 \rightarrow \text{PhCH}=\text{NR}$.²¹³⁷

OS VI, 751.

NUCLEOPHILIC SUBSTITUTION AT A SULFONYL SULFUR ATOM²¹³⁸

Nucleophilic substitution at RSO_2X is similar to attack at RCOX . Many of the reactions are essentially the same, though sulfonyl halides are less reactive than halides of carboxylic acids.²¹³⁹ The mechanisms²¹⁴⁰ are not identical, because a "tetrahedral" intermediate in this case (**121**) would have five groups on the central atom. This is possible since sulfur can accommodate up to 12 electrons in its valence shell, but it seems more likely that these mechanisms more closely resemble the $\text{S}_{\text{N}}2$ mechanism, with a trigonal-bipyramidal transition state (**122**). There are two major experimental results leading to this conclusion.

1. The stereospecificity of this reaction is more difficult to determine than that of nucleophilic substitution at a saturated carbon, where chiral compounds are relatively easy to prepare, but it may be recalled (p. 142) that optical activity is possible in a compound of the form RSO_2X if one oxygen is ^{16}O and the other ^{18}O . When a sulfonate ester possessing this type of chirality was converted to a sulfone with a Grignard reagent (**16-105**), inversion of configuration was found.²¹⁴¹ This is not incompatible with an intermediate such as **121** but it is also in good accord with an $\text{S}_{\text{N}}2$ -like mechanism with backside attack.

2. More direct evidence against **121** (though still not conclusive) was found in an experiment involving acidic and basic hydrolysis of aryl arenesulfonates, where it has been shown by the use of ^{18}O that an intermediate like **121** is not reversibly formed, since ester recovered when the reaction was stopped before completion contained no ^{18}O when the hydrolysis was carried out in the presence of labeled water.²¹⁴²

Other evidence favoring the $\text{S}_{\text{N}}2$ -like mechanism comes from kinetics and substituent effects.²¹⁴³ However, evidence for the mechanism involving **121** is that the rates did not change much with changes in the leaving group²¹⁴⁴ and the ρ values were large, indicating that a negative charge builds up in the transition state.²¹⁴⁵

In certain cases in which the substrate carries an α hydrogen, there is strong evidence²¹⁴⁶ that at least some of the reaction takes place by an elimination-addition mechanism (E1cB, similar to the one shown on p. 1406), going through a *sulfene* intermediate,²¹⁴⁷ for example, the reaction between methanesulfonyl chloride and aniline.

In the special case of nucleophilic substitution at a sulfonic ester $\text{RSO}_2\text{OR}'$, where R' is alkyl, $\text{R}'\text{-O}$ cleavage is much more likely than S-O cleavage because the OSO_2R group is such a good leaving group (p. 497).²¹⁴⁸ Many of these reactions have been considered previously (e.g., **10-4**, **10-10**), because they are nucleophilic substitutions at an alkyl carbon atom and not at a sulfur atom. However, when R' is aryl, then the S-O bond is much more likely to cleave because of the very low tendency aryl substrates have for nucleophilic substitution.²¹⁴⁹

The order of nucleophilicity toward a sulfonyl sulfur has been reported as $\text{OH}^- > \text{RNH}_2 > \text{N}_3^- > \text{F}^- > \text{AcO}^- > \text{Cl}^- > \text{H}_2\text{O} > \text{I}^-$.²¹⁵⁰ This order is similar to that at a carbonyl carbon (p. \$\$\$). Both of these substrates can be regarded as relatively hard acids, compared to a saturated carbon which is considerably softer and which has a different order of nucleophilicity (p. 494).

16-100 Attack by OH: Hydrolysis of Sulfonic Acid Derivatives

S-Hydroxy-de-chlorination, etc.

Sulfonyl chlorides as well as esters and amides of sulfonic acids can be hydrolyzed to the corresponding acids. Sulfonyl chlorides can be hydrolyzed with water or with an alcohol in the absence of acid or base. Basic catalysis is also used, though of course the salt is the product obtained. Esters are readily hydrolyzed, many with water or dilute alkali. This is the same reaction as **10-4**, and usually involves $\text{R}'\text{-O}$ cleavage, except when R' is aryl. However, in some cases retention of configuration has been shown at alkyl R' , indicating S-O cleavage in these cases.²¹⁵¹ Sulfonamides are generally *not* hydrolyzed by alkaline treatment, not even with hot concentrated alkali. Acids, however, do hydrolyze sulfonamides, but less readily than they do sulfonyl halides or sulfonic esters. Of course, ammonia or the amine appears as the salt. However, sulfonamides can be hydrolyzed with base if the solvent is HMPA.²¹⁵²

Magnesium in methanol has been used to convert sulfonate esters to the parent alcohol.²¹⁵³ Likewise, $\text{CeCl}_3 \cdot 7\text{H}_2\text{O} - \text{NaI}$ in acetonitrile converted aryl tosylates to the parent phenol derivative.²¹⁵⁴

²¹⁴⁸A number of sulfonates in which R contains a branching, for example, $\text{Ph}_2\text{C}(\text{CF}_3)\text{SO}_2\text{OR}'$, can be used to ensure that there will be no S-O cleavage: Netscher, T.; Prinzbach, H. *Synthesis* **1987**, 683.

16-101 Attack by OR. Formation of Sulfonic Esters

S-Alkoxy-de-chlorination, and so on

Sulfonic esters are most frequently prepared by treatment of the corresponding sulfonyl halides with alcohols in the presence of a base. This procedure is the most common method for the conversion of alcohols to tosylates, brosylates, and similar sulfonic esters. Both R and R' may be alkyl or aryl. The base is often pyridine, which functions as a nucleophilic catalyst,²¹⁵⁵ as in the similar alcoholysis of carboxylic acyl halides (**16-61**). Propylenediamines have also been used to facilitate tosylation of an alcohol.²¹⁵⁶ Silver oxide has been used, in conjunction with KI.²¹⁵⁷ Primary alcohols react the most rapidly, and it is often possible to sulfonate selectively a primary OH group in a molecule that also contains secondary or tertiary OH groups. The reaction with sulfonamides has been much less frequently used and is limited to *N,N*-disubstituted sulfonamides; that is, R— may not be hydrogen. However, within these limits it is a useful reaction. The nucleophile in this case is actually RO⁻. However, R' may be hydrogen (as well as alkyl) if the nucleophile is a phenol, so that the product is RSO₂OAr. Acidic catalysts are used in this case.²¹⁵⁸ Sulfonic acids have been converted directly to sulfonates by treatment with triethyl or trimethyl orthoformate, HC(OR)₃, without catalyst or solvent,²¹⁵⁹ and with a trialkyl phosphite, P(OR)₃.²¹⁶⁰

Mono-tosylation of a 1,2-diol was achieved using tosyl chloride and triethylamine, with a tin oxide catalyst.²¹⁶¹

16-102 Attack by Nitrogen: Formation of Sulfonamides**S-Amino-de-chlorination**

The treatment of sulfonyl chlorides with ammonia or amines is the usual way of preparing sulfonamides. Primary amines give *N*-alkyl sulfonamides, and secondary amines give *N,N*-dialkyl sulfonamides. The reaction is the basis of the *Hinsberg test* for distinguishing between primary, secondary, and tertiary amines. *N*-Alkyl sulfonamides, having an acidic hydrogen, are soluble in alkali, while *N,N*-dialkyl sulfonamides are not. Since tertiary amines are usually recovered unchanged, primary, secondary, and tertiary amines can be told apart. However, the test is limited for at least two reasons.²¹⁶² (1) Many *N*-alkyl sulfonamides in which the alkyl group has six or more carbons are insoluble in alkali, despite their acidic hydrogen,²¹⁶³ so that a primary amine may appear to be a secondary amine. (2) If the reaction conditions are not carefully controlled, tertiary amines may not be recovered unchanged.²¹⁶⁰

A primary or a secondary amine can be protected by reaction with phenacetyl sulfonyl chloride, (PhCOCH₂SO₂Cl), to give a sulfonamide, RNHSO₂CH₂COPh or R₂NSO₂CH₂COPh.²¹⁶⁴ The protecting group can be removed when desired with zinc and acetic acid. Sulfonyl chlorides react with azide ion to give sulfonyl azides (RSO₂N₃).²¹⁶⁵ Chlorothioformates, ROC(=S)Cl, react with triethylamine to give the *N,N*-diethylthioamide.²¹⁶⁶

A quite different synthesis of sulfonamides treated allyltributyltin with PhI=NTs, in the presence of copper (II) triflate.²¹⁶⁷ another alternative method treats silyl enol ethers with sulfur dioxide, and subsequent and reaction with a secondary amine gave the β-sulfonamido ester.²¹⁶⁸

This reaction, parallel with **16-79**, is the standard method for the preparation of sulfonyl halides. Also used are PCl_3 and SOCl_2 , and sulfonic acid salts can also serve as substrates. Cyanuric acid (2,4,6-trichloro[1,3,5]triazene) also serves as a chlorinating agent.²¹⁶⁹ Sulfonyl bromides and iodides have been prepared from sulfonyl hydrazides ($\text{ArSO}_2\text{NHNH}_2$, themselves prepared by **16-102**) by treatment with bromine or iodine.²¹⁷⁰ Sulfonyl fluorides are generally prepared from the chlorides, by halogen exchange.²¹⁷¹

OS I, 84; IV, 571, 693, 846, 937; V, 196. See also, OS VII, 495.

16-104 Attack by Hydrogen: Reduction of Sulfonyl Chlorides

S-Hydro-de-chlorination or S-Dechlorination

Sulfinic acids can be prepared by reduction of sulfonyl chlorides. Though mostly done on aromatic sulfonyl chlorides, the reaction has also been applied to alkyl compounds. Besides zinc, sodium sulfite, hydrazine, sodium sulfide, and other reducing agents have been used. For reduction of sulfonyl chlorides to thiols, see **19-78**.

OS I, 7, 492; IV, 674.

16-105 Attack by Carbon: Preparation of Sulfones

S-Aryl-de-chlorination

Grignard reagents convert aromatic sulfonyl chlorides or aromatic sulfonates to sulfones. Organolithium reagents react with sulfonyl fluorides at -78°C to give the corresponding sulfone.²¹⁷² Aromatic sulfonates have also been converted to sulfones with organolithium compounds,²¹⁷³ with aryltin compounds,²¹⁷⁴ and with alkyl halides and Zn metal.²¹⁷⁵ Vinylic and allylic sulfones have been prepared by treatment of sulfonyl chlorides with a vinylic or allylic stannane and a palladium complex catalyst.²¹⁷⁶ Alkynyl sulfones can be prepared by treatment of sulfonyl chlorides with trimethylsilylalkynes, with an AlCl_3 catalyst.²¹⁷⁷ Note that

Eliminations

When two groups are lost from adjacent atoms so that a new double¹

(or triple) bond is formed the reaction is called β -*elimination*; one atom is the α , the other the β atom. In an α elimination, both groups are lost from the same atom to give a carbene (or a nitrene):

In a γ elimination, a three-membered ring is formed:

Some of these processes were discussed in Chapter 10. Another type of elimination involves the expulsion of a fragment from within a chain or ring ($\text{X-Y-Z} \rightarrow \text{X-Z} + \text{Y}$). Such reactions are called *extrusion reactions*. This chapter discusses β -elimination and (beginning on p. 1553) extrusion reactions; however, β -elimination in which both X and W are hydrogens are oxidation reactions and are treated in Chapter 19.

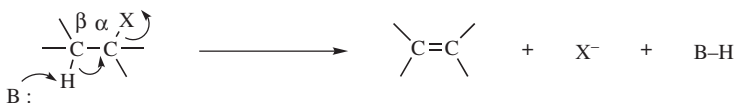

¹See Williams, J.M.J. *Preparation of Alkenes, A Practical Approach*, Oxford University Press, Oxford, 1996.

MECHANISMS AND ORIENTATION

β -Elimination reactions may be divided into two types; one type taking place largely in solution, the other (pyrolytic eliminations) mostly in the gas phase. In the reactions in solution, one group leaves with its electrons and the other without, the latter most often being hydrogen. In these cases, we refer to the former as the leaving group or nucleofuge. For pyrolytic eliminations, there are two principal mechanisms, one pericyclic and the other a free-radical pathway. A few photochemical eliminations are also known (the most important is Norrish type II cleavage of ketones, p. 344), but these are not generally of synthetic importance² and will not be discussed further. In most β -eliminations the new bonds are $C=C$ or $C\equiv C$; our discussion of mechanisms is largely confined to these cases.³ Mechanisms in solution (E_2 , E_1)⁴ and E_1cB are discussed first.

The E_2 Mechanism

In the E_2 mechanism (elimination, bimolecular), the two groups depart simultaneously, with the proton being pulled off by a base:

The mechanism thus takes place in one step and kinetically is second order: first order in substrate and first order in base. An *ab initio* study has produced a model for the E_2 transition state geometry.⁵ The IUPAC designation is $A_{xH}D_{HD_N}$, or more generally (to include cases where the electrofuge is not hydrogen), $A_nD_{ED_N}$. It is analogous to the S_N2 mechanism (p. 426) and often competes with it. With respect

to the substrate, the difference between the two pathways is whether the species with the unshared pair attacks the carbon (and thus acts as a nucleophile) or the hydrogen (and thus acts as a base). As in the case of the S_N2 mechanism, the leaving group may be positive or neutral and the base may be negatively charged or neutral.

Among the evidence for the existence of the E2 mechanism are (1) the reaction displays the proper second-order kinetics; (2) when the hydrogen is replaced by deuterium in second-order eliminations, there is an isotope effect of from 3 to 8, consistent with breaking of this bond in the rate-determining step.⁶ However, neither of these results alone could prove an E2 mechanism, since both are compatible with other mechanisms also (e.g., see E1cB p. 1488). The most compelling evidence for the E2 mechanism is found in stereochemical studies.⁷ As will be illustrated in the examples below, the E2 mechanism is stereospecific: The five atoms involved (including the base) in the transition state must be in one plane. There are two ways for this to happen. The H and X may be

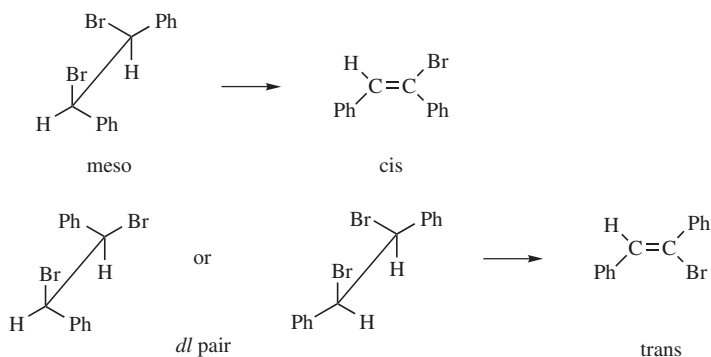

trans to one another (**A**) with a dihedral angle of 180° , or they may be cis (**B**) with a dihedral angle of 0° .⁸ Conformation **A** is called *anti-periplanar*, and this type of elimination, in which H and X depart in opposite directions, is called *anti-elimination*. Conformation **B** is *syn-periplanar*, and this type of elimination, with H and X leaving in the same direction, is called *syn-elimination*. Many examples of both kinds have been discovered. In the absence of special effects (discussed below) anti-elimination is usually greatly favored over syn-elimination, probably because **A** is a staggered conformation (p. 199) and the molecule requires less energy to reach this transition state than it does to reach the eclipsed transition state **B**. A few of the many known examples of predominant or exclusive anti-elimination follow.

⁶See, for example, Saunders, Jr., W.H.; Edison, D.H. *J. Am. Chem. Soc.* **1960**, *82*, 138; Shiner, Jr., V.J.; Smith, M.L. *J. Am. Chem. Soc.* **1958**, *80*, 4095; **1961**, *83*, 593. For a review of isotope effects in elimination reactions, see Fry, A. *Chem. Soc. Rev.* **1972**, *1*, 163.

⁸DePuy, C.H.; Morris, G.F.; Smith, J.S.; Smat, R.J. *J. Am. Chem. Soc.* **1965**, *87*, 2421.

1. Elimination of HBr from *meso*-1,2-dibromo-1,2-diphenylethane gave *cis*-2-bromostilbene, while the (+) or (-) isomer gave the *trans* alkene. This stereospecific result, which

was obtained in 1904,⁹ demonstrates that in this case elimination is anti. Many similar examples have been discovered since. Obviously, this type of experiment need not be restricted to compounds that have a *meso* form. Anti-elimination requires that an erythro *dl* pair (or either isomer) give the *cis* alkene, and the threo *dl* pair (or either isomer) give the *trans* isomer, and this has been found many times. Anti-elimination has also been demonstrated in cases where the electrofuge is not hydrogen. In the reaction of 2,3-dibromobutane with iodide ion, the two bromines are removed (**17-22**). In this case, the *meso* compound gave the *trans* alkene and the *dl* pair the *cis*.¹⁰

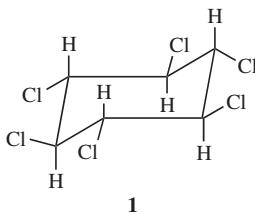

2. In open-chain compounds, the molecule can usually adopt that conformation in which H and X are anti-periplanar. However, in cyclic systems this is not always the case. There are nine stereoisomers of 1,2,3,4,5,6-hexachlorocyclohexane: seven *meso* forms and a *dl* pair (see p. 165). Four of the *meso* compounds and the *dl* pair (all that were then known) were subjected to

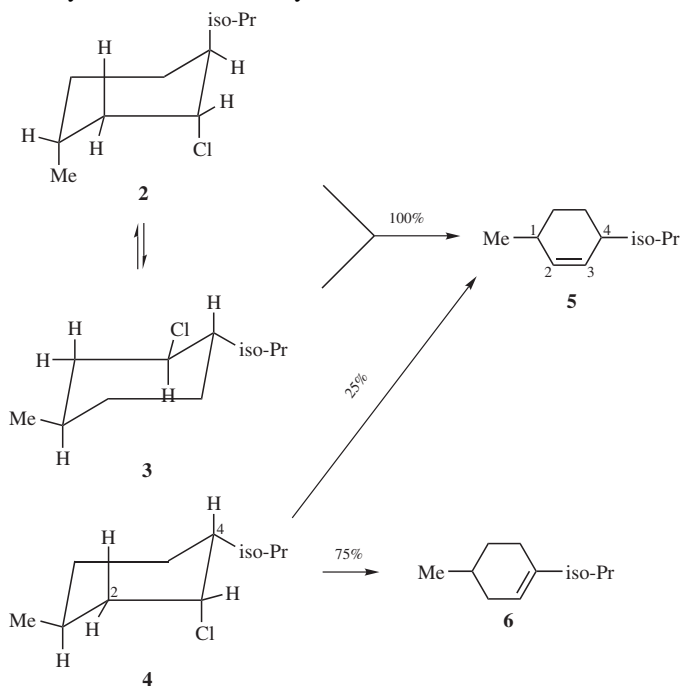

⁹Pfeiffer, P. Z. *Phys. Chem.* **1904**, 48, 40.

¹⁰Winstein, S.; Pressman, D.; Young, W.G. *J. Am. Chem. Soc.* **1939**, 61, 1645.

elimination of HCl. Only one of these (**1**) has no Cl trans to an H. Of the other isomers, the fastest elimination rate was about three times as fast as the slowest, but the rate for **1** was 7000 times slower than that of the slowest of the other isomers.¹¹ This result demonstrates that with these compounds anti elimination is greatly favored over syn elimination, although the latter must be taking place on **1**, very slowly, to be sure.

3. The preceding result shows that elimination of HCl in a six-membered ring proceeds best when the H and X are trans to each other. However, there is an additional restriction. Adjacent trans groups on a six-membered ring can be diaxial or diequatorial (p. 204) and the molecule is generally free to adopt either conformation, although one may have a higher energy than the other. Anti-periplanarity of the leaving groups requires that they be diaxial, even if this is the conformation of higher energy. The results with menthyl and neomenthyl chlorides are easily

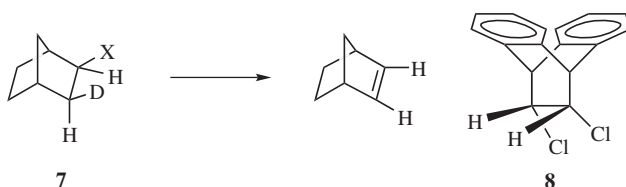

¹¹Cristol, S.J.; Hause, N.L.; Meek, J.S. *J. Am. Chem. Soc.* **1951**, 73, 674.

interpretable on this basis. Menthyl chloride has two chair conformations, **2** and **3**. Compound **3**, in which the three substituents are all equatorial, is the more stable. The more stable chair conformation of neomenthyl chloride is **4**, in which the chlorine is axial; there are axial hydrogens on both C-2 and C-4. The results are: neomenthyl chloride gives rapid E2 elimination and the alkene produced is predominantly **6** (**6/5** ratio is 3:1) in accord with Zaitsev's rule (p. 767). Since an axial hydrogen is available on both sides, this factor does not control the direction of elimination and Zaitsev's rule is free to operate. However, for menthyl chloride, elimination is much slower and the product is entirely the anti-Zaitsev, **5**. It is slow because the unfavorable conformation **2** has to be achieved before elimination can take place, and the product is **5** because only on this side is there an axial hydrogen.¹²

4. That anti-elimination also occurs in the formation of triple bonds is shown by elimination from *cis*- and *trans*-HOOC-CH=C(Cl)COOH. In this case, the product in both cases is HOCC≡CCOOH, but the *trans* isomer reacts ~50 times faster than the *cis* compound.¹³

Some examples of syn-elimination have been found in molecules where H and X could not achieve an anti-periplanar conformation.

1. The deuterated norbornyl bromide (**7**, X = Br) gave 94% of the product containing no deuterium.¹⁴ Similar results were obtained with other leaving groups and with bicyclo[2.2.2] compounds.¹⁵ In these cases the *exo* X group cannot achieve a dihedral angle of 180° with the *endo* β hydrogen because of the rigid structure of the molecule. The dihedral angle here is ~120°. These leaving groups prefer syn-elimination with a dihedral angle of ~0° to anti-elimination with an angle of ~120°.

¹⁴Kwart, H.; Takeshita, T.; Nyce, J.L. *J. Am. Chem. Soc.* **1964**, 86, 2606.

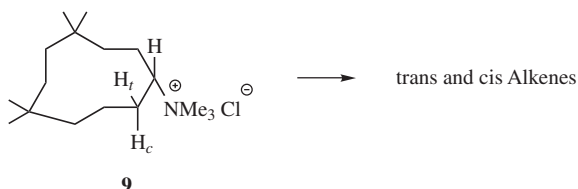

¹⁵For example, see Bird, C.W.; Cookson, R.C.; Hudec, J.; Williams, R.O. *J. Chem. Soc.* **1963**, 410; Stille, J.K.; Sonnenberg, F.M.; Kinstle, T.H. *J. Am. Chem. Soc.* **1966**, 88, 4922; Coke, J.L.; Cooke, Jr., M.P. *J. Am. Chem. Soc.* **1967**, 89, 6701; DePuy, C.H.; Naylor, C.G.; Beckman, J.A. *J. Org. Chem.* **1970**, 35, 2750; Brown, H.C.; Liu, K. *J. Am. Chem. Soc.* **1970**, 92, 200; Sicher, J.; Pánkova, M.; Závada, J.; Kniežo, L.; Oráhovats, A. *Collect. Czech. Chem. Commun.* **1971**, 36, 3128; Bartsch, R.A.; Lee, J.G. *J. Org. Chem.* **1991**, 56, 212, 2579.

2. Molecule **8** is a particularly graphic example of the need for a planar transition state. In **8**, each Cl has an adjacent hydrogen trans to it, and if planarity of leaving groups were not required, anti-elimination could easily take place. However, the crowding of the rest of the molecule forces the dihedral angle to be $\sim 120^\circ$, and elimination of HCl from **8** is much slower than from corresponding nonbridged compounds.¹⁶ (Note that syn elimination from **8** is even less likely than anti-elimination.) Syn-elimination can take place from the trans isomer of **8** (dihedral angle $\sim 0^\circ$); this isomer reacted about eight times faster than **8**.¹⁶

The examples so far given illustrate two points. (1) Anti-elimination *requires* a dihedral angle of 180° . When this angle cannot be achieved, anti-elimination is greatly slowed or prevented entirely. (2) For the simple systems so far discussed syn-elimination is not found to any significant extent unless anti elimination is greatly diminished by failure to achieve the 180° angle.

As noted in Chapter 4 (p. 223), six-membered rings are the only ones among rings of 4–13 members in which strain-free anti-periplanar conformations can be achieved. It is not surprising, therefore, that syn elimination is least common in six-membered rings. Cooke and Coke subjected cycloalkyltrimethylammonium hydroxides to elimination (**17-7**) and found the following percentages of syn-elimination with ring size: four-membered, 90%; five-membered, 46%; six-membered, 4% seven-membered, 31 to 37%.¹⁷ Note that the NMe_3^+ group has a greater tendency to syn-elimination than do other common leaving groups, such as OTs, Cl, and Br.

Other examples of syn-elimination have been found in medium-ring compounds, where both *cis* and *trans* alkenes are possible (p. 184). As an illustration, we can look at experiments performed by, Svoboda, and Sicher.¹⁸ These workers subjected 1,1,4,4-tetramethyl-7-cyclodecyltrimethylammonium chloride (**9**) to

elimination and obtained mostly *trans*-, but also some *cis*-tetramethylcyclodecenes as products. (Note that *trans*-cyclodecenes, although stable, are less stable than the *cis* isomers). In order to determine the stereochemistry of the reaction, they repeated the elimination, this time using deuterated substrates. They found that

¹⁶Cristol, S.J.; Hause, N.L. *J. Am. Chem. Soc.* **1952**, *74*, 2193.

¹⁷Cooke, Jr., M.P.; Coke, J.L. *J. Am. Chem. Soc.* **1968**, *90*, 5556. See also, Coke, J.L.; Smith, G.D.; Britton, Jr., G.H. *J. Am. Chem. Soc.* **1975**, *97*, 4323.

¹⁸Závada, J.; Svoboda, M.; Sicher, J. *Tetrahedron Lett.* **1966**, 1627; *Collect. Czech. Chem. Commun.* **1968**, *33*, 4027.

when **9** was deuterated in the trans position ($H_t = D$), there was a substantial isotope effect in the formation of *both* cis and trans alkenes, but when **9** was deuterated in the cis position ($H_c = D$), there was *no* isotope effect in the formation of either alkene. Since an isotope effect is expected for an E2 mechanism,¹⁹ these results indicated that *only* the trans hydrogen (H_t) was lost, whether the product was the cis or the trans isomer.²⁰ This in turn means that *the cis isomer must have been formed by anti-elimination and the trans isomer by syn-elimination*. (Anti-elimination could take place from approximately the conformation shown, but for syn elimination the molecule must twist into a conformation in which the C– H_t and C– NMe_3^+ bonds are syn-periplanar.) This remarkable result, called the *syn-anti dichotomy*, has also been demonstrated by other types of evidence.²¹ The fact that syn-elimination in this case predominates over anti (as indicated by the formation of trans isomer in greater amounts than cis) has been explained by conformational factors.²² The syn-anti dichotomy has also been found in other medium-ring systems (8–12 membered),²³ although the effect is greatest for 10-membered rings. With leaving groups,²⁴ the extent of this behavior decreases in the order $^+NMe_3 > OTs > Br > Cl$, which parallels steric requirements. When the leaving group is uncharged, syn-elimination is favored by strong bases and by weakly ionizing solvents.²⁵

Syn-elimination and the syn-anti dichotomy have also been found in open-chain systems, although to a lesser extent than in medium-ring compounds. For example, in the conversion of 3-hexyl-4-*d*-trimethylammonium ion to 3-hexene with potassium *sec*-butoxide, ~67% of the reaction followed the syn-anti dichotomy.²⁶ In general syn-elimination in open-chain systems is only important in cases where certain types of steric effect are present. One such type is compounds in which substituents are found on both the β' and the γ carbons (the unprimed letter refers to the branch in which the elimination takes place). The factors that cause these results are not

¹⁹Other possible mechanisms, such as E1cB (p. 1488) or α',β elimination (p. 1524), were ruled out in all these cases by other evidence.

²⁰This conclusion has been challenged by Coke, J.L. *Sel. Org. Transform.* **1972**, 2, 269.

²¹Sicher, J.; Závada, J. *Collect. Czech. Chem. Commun.* **1967**, 32, 2122; Závada, J.; Sicher, J. *Collect. Czech. Chem. Commun.* **1967**, 32, 3701. For a review, see Bartsch, R.A.; Závada, J. *Chem. Rev.* **1980**, 80, 453.

²⁶Bailey, D.S.; Saunders Jr., W.H. *J. Am. Chem. Soc.* **1970**, 92, 6904. For other examples of syn-elimination and the syn-anti dichotomy in open-chain systems, see Pánková, M.; Vitek, A.; Vasířková, S.; Řeřicha, R.; Závada, J. *Collect. Czech. Chem. Commun.* **1972**, 37, 3456; Schlosser, M.; An, T.D. *Helv. Chim. Acta* **1979**, 62, 1194; Sugita, T.; Nakagawa, J.; Nishimoto, K.; Kasai, Y.; Ichikawa, K. *Bull. Chem. Soc. Jpn.* **1979**, 52, 871; Pánková, M.; Kocián, O.; Krupička, J.; Závada, J. *Collect. Czech. Chem. Commun.* **1983**, 48, 2944.

completely understood, but the following conformational effects have been proposed as a partial explanation.²⁷ The two anti- and two syn-periplanar conformations are, for a quaternary ammonium salt:

In order for an E2 mechanism to take place, a base must approach the proton marked *. In **C**, this proton is shielded on both sides by R and R'. In **D**, the shielding is on only one side. Therefore, when anti-elimination does take place in such systems, it should give more cis product than trans. Also, when the normal anti elimination pathway is hindered sufficiently to allow the syn pathway to compete, the anti → trans route should be diminished more than the anti → cis route. When syn-elimination begins to appear, it seems clear that **E**, which is less eclipsed than **F**, should be the favored pathway and syn-elimination should generally give the trans isomer. In general, deviations from the syn-anti dichotomy are greater on the trans side than on the cis. Thus, trans alkenes are formed partly or mainly by syn-elimination, but cis alkenes are formed entirely by anti-elimination. Predominant syn-elimination has also been found in compounds of the form $R^1R^2CHCHDNMe_3^+$, where R¹ and R² are both bulky.²⁸ In this case, the conformation leading to syn-elimination (**H**) is also less strained than **G**, which gives anti-elimination. The **G** compound has three bulky groups (including NMe_3^+) in the *gauche* position to each other.

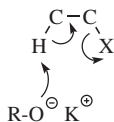

It was mentioned above that weakly ionizing solvents promote syn-elimination when the leaving group is uncharged. This is probably caused by ion pairing, which

²⁷Bailey, D.S.; Saunders, Jr., W.H. *J. Am. Chem. Soc.* **1970**, *92*, 6904; Chiao, W.; Saunders, Jr., W.H. *J. Am. Chem. Soc.* **1977**, *99*, 6699.

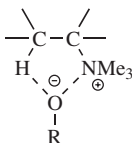

²⁸Dohner, B.R.; Saunders Jr., W.H. *J. Am. Chem. Soc.* **1986**, *108*, 245.

is greatest in nonpolar solvents.²⁹ Ion pairing can

10

cause syn-elimination with an uncharged leaving group by means of the transition state shown in **10**. This effect was graphically illustrated by elimination from 1,1,4,4-tetramethyl-7-cyclodecyl bromide.³⁰ The ratio of syn-to-anti-elimination when this compound was treated with *t*-BuOK in the nonpolar benzene was 55.0. But when the crown ether dicyclohexano-18-crown-6 was added (this compound selectively removes K^+ from the $t\text{-BuO}^- K^+$ ion pair and thus leaves $t\text{-BuO}^-$ as a free ion), the syn/anti ratio decreased to 0.12. Large decreases in the syn/anti ratio on addition of the crown ether were also found with the corresponding tosylate and with other nonpolar solvents.³¹ However, with positively charged leaving groups the effect is reversed. Here, ion pairing *increases* the amount of anti-elimination.³² In this case, a relatively free base (e.g., PhO^-) can be attracted to the leaving group, putting it in a favorable position for attack on the syn β hydrogen, while ion pairing would reduce this attraction.

We can conclude that anti-elimination is generally favored in the E2 mechanism, but that steric (inability to form the anti-periplanar transition state), conformational, ion pairing, and other factors cause syn-elimination to intervene (and even predominate) in some cases.

The E1 Mechanism

The E1 mechanism is a two-step process in which the rate-determining step is ionization of the substrate to give a carbocation that rapidly loses a β proton to a base, usually the solvent:

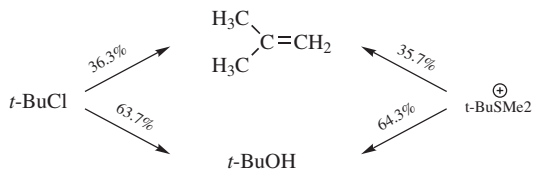

The IUPAC designation is $D_N + D_E$ (or $D_N + D_H$). This mechanism normally operates without an *added* base. Just as the E2 mechanism is analogous to and competes with the S_N2 , so is the E1 mechanism related to the S_N1 . In fact, the first step of the E1 is exactly the same as that of the S_N1 mechanism. The second step differs in that the solvent pulls a proton from the β carbon of the carbocation rather than attacking it at the positively charged carbon, as in the S_N1 process. In a pure E1 reaction (without ion pairs, etc.), the product should be completely nonstereospecific, since the carbocation is free to adopt its most stable conformation before giving up the proton.

Some of the evidence for the E1 mechanism is as follows:

1. The reaction exhibits first-order kinetics (in substrate) as expected. Of course, the solvent is not expected to appear in the rate equation, even if it were involved in the rate-determining step (p. 316), but this point can be easily checked by adding a small amount of the conjugate base of the solvent. It is generally found that such an addition does not increase the rate of the reaction. If this more powerful base does not enter into the rate-determining step, it is unlikely that the solvent does. An example of an E1 mechanism with a rate-determining second step (proton transfer) has been reported.³³
2. If the reaction is performed on two molecules that differ only in the leaving group (e.g., *t*-BuCl and *t*-BuSMe₂⁺), the rates should obviously be different, since they depend on the ionizing ability of the molecule. However, once the carbocation is formed, if the solvent and the temperature are the same, it should suffer the same fate in both cases, since the nature of the leaving group does not affect the second step. This means that *the ratio of elimination to substitution should be the same*. The compounds mentioned in the example were solvolyzed at 65.3°C in 80% aqueous ethanol with the following results:³⁴

³³Baciocchi, E.; Clementi, S.; Sebastiani, G.V.; Ruzziconi, R. *J. Org. Chem.* **1979**, *44*, 32.

³⁴Cooper, K.A.; Hughes, E.D.; Ingold, C.K.; MacNulty, B.J. *J. Chem. Soc.* **1948**, 2038.

Although the rates were greatly different (as expected with such different leaving groups), the product ratios were the same, within 1%. If this had taken place by a second-order mechanism, the nucleophile would not be expected to have the same ratio of preference for attack at the β hydrogen compared to attack at a *neutral* chloride as for attack at the β hydrogen compared to attack at a *positive* SMe_2 group.

- Many reactions carried out under first-order conditions on systems where E2 elimination is anti proceed quite readily to give alkenes where a cis hydrogen must be removed, often in preference to the removal of a trans hydrogen. For example, menthyl chloride (**2**, p. 1482), which by the E2 mechanism gave only **5**, under E1 conditions gave 68% **6** and 32% **5**, since the steric nature of the hydrogen is no longer a factor here, and the more stable alkene (Zaitsev's rule, p. 1482) is predominantly formed.
- If carbocations are intermediates, we should expect rearrangements with suitable substrates. These have often been found in elimination reactions performed under E1 conditions.

E1 reactions can involve ion pairs, just as is true for $\text{S}_{\text{N}}1$ reactions (p. 437).³⁵ This effect is naturally greatest for nondissociating solvents: It is least in water, greater in ethanol, and greater still in acetic acid. It has been proposed that the ion-pair mechanism (p. 439) extends to elimination reactions too, and that the $\text{S}_{\text{N}}1$, $\text{S}_{\text{N}}2$, E1, and E2 mechanisms possess in common an ion-pair intermediate, at least occasionally.³⁶

The E1cB Mechanism³⁷

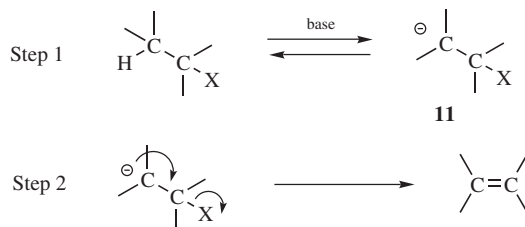

In the E1 mechanism, X leaves first and then H. In the E2 mechanism, the two groups leave at the same time. There is a third possibility: The H leaves first,

and then the X. This is a two-step process, called the E1cB *mechanism*,³⁸ or the *carbanion mechanism*, since the intermediate is a carbanion:

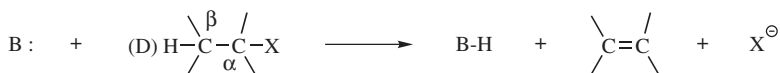

The name E1cB comes from the fact that it is the conjugate base of the substrate that is giving up the leaving group (see the S_N1cB mechanism, p. 521). The IUPAC designation is A_nD_E + D_N or A_{xh}D_H + D_N (see p. 420). We can distinguish three limiting cases: (1) The carbanion returns to starting material faster than it forms product: step 1 is reversible; step 2 is slow. (2) Step 1 is the slow step, and formation of product is faster than return of the carbanion to starting material. In this case, step 1 is essentially irreversible. (3) Step 1 is rapid, and the carbanion goes slowly to product. This case occurs only with the most stable carbanions. Here, too, step 1 is essentially irreversible. These cases have been given the designations: (1) (E1cB)_R, (2) (E1cB)_I (or E1cB_{irr}), and (3) (E1)_{anion}. Their characteristics are listed in Table 17.1.³⁹ Investigations of the reaction order are generally not very useful (except for case 3, which is first order), because cases 1 and 2 are second order and thus difficult or impossible to distinguish from the E2 mechanism by this procedure.⁴⁰ We would expect the greatest likelihood of finding the E1cB mechanism in substrates that have (a) a poor nucleofuge and (b) an acidic hydrogen, and most investigations have concerned such substrates. The following is some of the evidence in support of the E1cB mechanism:

1. The first step of the (E1cB)_R mechanism involves a reversible exchange of protons between the substrate and the base. In that case, if deuterium is present in the base, recovered starting material should contain deuterium. This was found to be the case in the treatment of Cl₂C=CHCl with NaOD to give ClC≡CCl. When the reaction was stopped before completion, there *was*

³⁸For a discussion, see Ryberg, P.; Matsson, O. *J. Org. Chem.* **2002**, *67*, 811.

³⁹This table, which appears in Cockerill, A.F.; Harrison, R.G. in Bamford, C.H.; Tipper, C.F.H. *Comprehensive Chemical Kinetics*, Vol. 9, Elsevier, NY, **1973**, p. 161, was adapted from a longer one, in Bordwell, F.G. *Acc. Chem. Res.* **1972**, *5*, 374, see p. 375.

⁴⁰(E1cB)_I cannot be distinguished from E2 by this means, because it has the identical rate law: Rate = *k*[substrate][B⁻]. The rate law for (E1cB)_R is different: Rate = *k*[substrate][B⁻]/[BH], but this is often not useful because the only difference is that the rate is also dependent (inversely) on the concentration of the conjugate acid of the base, and this is usually the solvent, so that changes in its concentration cannot be measured.

TABLE 17.1. Kinetic Predictions for Base-Induced β -Eliminations³⁹

Mechanism	Kinetic ^a Order	β -Hydrogen Exchange Faster Than Elimination	General or Specific Base Catalysis	$k_{\text{H}}/k_{\text{D}}$	Electron Withdrawal at $\text{C}\beta^{\text{d}}$	Electron release at $\text{C}\alpha^{\text{d}}$	Leaving- Group Isotope Effect or Element Effect
(E1) _{anion}	1	Yes	General ^c	1.0	Rate decrease	Rate increase	Substantial
(E1cB) _R	2	Yes	Specific	1.0	Small rate increase	Small rate increase	Substantial
(E1cB) _{ip}	2	No	General ^e	1.0 \rightarrow 1.2	Small rate increase	Small rate increase	Substantial
(E1cB) _I	2	No	General	2 \rightarrow 8	Rate increase	Little effect	Small to negligible
E2 ^b	2	No	General	2 \rightarrow 8	Rate increase	Small rate increase	Small

^aAll mechanism exhibit first-order kinetics in substrate.

^bOnly transition states with considerable carbanion character considered in this table.

^cSpecific base catalysis predicted if extent of substrate ionization reduced from almost complete.

^dEffect on rate assuming no change in mechanism is caused; steric factors upon substitution at $\text{C}\alpha$ and rise to $\text{C}\beta$ have not been considered. The rate reductions are geared to substituent effects such as those giving rise to Hammett reaction constants on β - and α -aryl substitution.

^eDepends on whether an ion pair assists in removal of leaving group.

deuterium in the recovered alkene.⁴¹ A similar result was found for pentahaloethanes.⁴² These substrates are relatively acidic. In both cases the electron-withdrawing halogens increase the acidity of the hydrogen, and in the case of trichloroethylene there is the additional factor that a hydrogen on an sp^2 carbon is more acidic than one on an sp^3 carbon (p. 388). Thus, the E1cB mechanism is more likely to be found in eliminations yielding triple bonds than in those giving double bonds. Another likely place for the E1cB mechanism should be in reaction of a substrate like $\text{PhCH}_2\text{CH}_2\text{Br}$, since the carbanion is stabilized by resonance with the phenyl group. Nevertheless, no deuterium exchange was found here.⁴³ If this type of evidence is a guide, then it may be inferred that the (E1cB)_R mechanism is quite rare, at least for eliminations with common leaving groups such as Br, Cl, or OTs, which yield $\text{C}=\text{C}$ double bonds.

⁴³Skell, P.S.; Hauser, C.R. *J. Am. Chem. Soc.* **1945**, *67*, 1661.

2. When the reaction

was carried out in water containing acetohydroxamate buffers, a plot of the rate against the buffer concentration was curved and the rate leveled off at high buffer concentrations, indicating a change in rate-determining step.⁴⁴ This rules out an E2 mechanism, which has only one step.⁴⁵ When D₂O was used instead of H₂O as solvent, there was an initial inverse solvent isotope effect of 7.7 (the highest inverse solvent isotope effect yet reported).

That is, the reaction took place faster in D₂O than in H₂O. This is compatible only with an E1cB mechanism in which the proton-transfer step is not entirely rate determining. The isotope effect arises from a partitioning of the carbanion intermediate **11**. This intermediate either can go to product or it can revert to starting compound, which requires taking a proton from the solvent. In D₂O, the latter process is slower (because the O–D bond of D₂O cleaves less easily than the O–H bond of H₂O), reducing the rate at which **11** returns to starting compound. With the return reaction competing less effectively, the rate of conversion of **11** to product is increased.

3. We have predicted that the E1cB mechanism would most likely be found with substrates containing acidic hydrogens and poor leaving groups. Compounds of the type ZCH₂CH₂Oph, where Z is an electron-withdrawing group (e.g., NO₂, SMe₂⁺, ArSO₂, CN, COOR), belong to this category, because Oph is a very poor leaving group (p. 438). There is much evidence to show that the mechanism here is indeed E1cB.⁴⁶ Isotope effects, measured for MeSOCD₂CH₂Oph and Me₂S⁺CD₂CH₂Oph with NaOD in D₂O, are ~0.7. This is compatible with an (E1cB)_R mechanism, but not with an E2 mechanism for which an isotope effect of perhaps 5 might be expected (of course, an E1 mechanism is precluded by the extremely poor nucleofugal ability of Oph). The fact that *k_H/k_D* is less than the expected value of 1 is attributable to solvent and secondary isotope effects. Among other evidence for an E1cB mechanism in these systems is that changes in the identity of Z had a dramatic effect on the relative rates: a span of 10¹¹ between NO₂ and COO[−]. Note that elimination from substrates of the type RCOCH₂CH₂Y is the reverse of Michael-type addition to C=C bonds. We have seen (p. \$\$\$) that such addition involves initial attack by a nucleophile Y and subsequent attack by a proton. Thus the initial loss of a proton from substrates of this type (i.e., an E1cB mechanism) is in accord with the principle of microscopic

reversibility.⁴⁷ It may also be recalled that benzyne formation (p. 859) can occur by such a process. It has been suggested that all base-initiated eliminations wherein the proton is activated by a strong electron-withdrawing group are E1cB reactions,⁴⁸ but there is evidence that this is not the case that when there is a good nucleofuge, the mechanism is E2 even when strong electron-withdrawing groups are present.⁴⁹ On the other hand, Cl⁻ has been found to be a leaving group in an E1cB reaction.⁵⁰

Of the three cases of the E1cB mechanism, the one most difficult to distinguish from E2 is (E1cB)₁. One way to make this distinction is to study the effect of a change in leaving group. This was done in the case of the three acenaphthylenes **12**, where it was found that (1) the three rates were fairly similar, the largest being only about

four times that of the smallest, and (2) in compound *c* (X = Cl, Y = F), the only product contained Cl and no F, that is, only the poorer nucleofuge F departed while Cl remained.⁵¹ Result (1) rules out all the E1cB mechanisms except (E1cB)₁, because the others should all have considerable leaving group effects (Table 17.1). An ordinary E2 mechanism should also have a large leaving group effect, but an E2 mechanism with substantial carbanionic character (see the next section) might not. However, no E2 mechanism can explain result (2), which can be explained by the fact that an a Cl is more effective than an a F in stabilizing the planar carbanion that remains when the proton is lost. Thus (as in the somewhat similar case of aromatic nucleophilic substitution, see p. 868), when X⁻ leaves in the second step, the one that leaves is not determined by which is the better nucleofuge, but by which has had its β hydrogen removed.⁵² Additional evidence for the existence of the

(E1cB)₁ mechanism was the observation of a change in the rate-determining step in the elimination reaction of *N*-(2-cyanoethyl)pyridinium

ions **13**, treated with base, when X was changed.⁵³ Once again, the demonstration that two steps are involved precludes the one-step E2 mechanism.

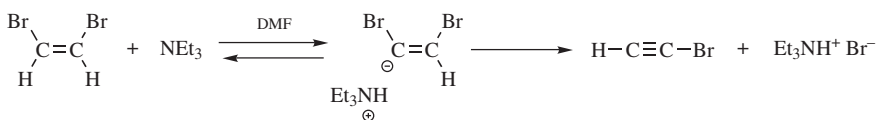

4. An example of an (E1)_{anion} mechanism has been found with the substrate **14**, which when treated with methoxide ion undergoes elimination to **16**, which is unstable under the reaction conditions and rearranges as

shown.⁵⁴ Among the evidence for the proposed mechanism in this case were kinetic and isotope-effect results, as well as the spectral detection of **15**.⁵⁵

5. In many eliminations to form C=O and C≡N bonds the initial step is loss of a positive group (normally a proton) from the oxygen or nitrogen. These may also be regarded as E1cB processes.

There is evidence that some E1cB mechanisms can involve carbanion ion pairs, for example,⁵⁶

This case is designated (E1cB)_{ip}; its characteristics are shown in Table 17.1.

The E1-E2-E1cB Spectrum

In the three mechanisms so far considered, the similarities are greater than the differences. In each case, there is a leaving group that comes off with its pair of electrons and another group (usually hydrogen) that comes off without them. The only difference is in the order of the steps. It is now generally accepted that there is a spectrum of mechanisms ranging from one extreme, in which the leaving group departs well before the proton (pure E1), to the other extreme, in which the proton comes off first and then, after some time, the leaving group follows (pure E1cB). The *pure* E2 case would be somewhere in the middle, with both groups leaving simultaneously. However, most E2 reactions are not exactly in the middle, but somewhere to one side or the other. For example, the nucleofuge might depart just before the proton. This case may be described as an E2 reaction with a small amount of E1 character. The concept can be expressed by the question: In the transition state, which bond (C–H or C–X) has undergone more cleavage?⁵⁷

One way to determine just where a given reaction stands on the E1-E2-E1cB spectrum is to study isotope effects, which ought to tell something about the behavior of bonds in the transition state.⁵⁸ For example, $\text{CH}_3\text{CH}_2\text{NMe}_3^+$ showed a nitrogen isotope effect (k^{14}/k^{15}) of 1.017, while $\text{PhCH}_2\text{CH}_2\text{NMe}_3^+$ gave a corresponding value of 1.009.⁵⁹ It would be expected that the phenyl group would move the reaction toward the E1cB side of the line, which means that for this compound the C–N bond is not as greatly broken in the transition state as it is for the unsubstituted one. The isotope effect bears this out, for it shows that in the phenyl compound, the mass of the nitrogen has less effect on the reaction rate than it does in the unsubstituted compound. Similar results have been obtained with SR_2^+ leaving groups by the use of $^{32}\text{S}/^{34}\text{S}$ isotope effects⁶⁰ and with Cl ($^{35}\text{Cl}/^{37}\text{Cl}$).⁶¹ The position of reactions along the spectrum has also been studied from the other side of the newly forming double bond by the use of H/D and H/T isotope effects,⁶² although interpretation of these results is clouded by the fact that β hydrogen isotope effects are expected to change smoothly from small to large to small again as the degree of transfer of the

β hydrogen from the β carbon to the base increases⁶³ (recall, p. \$\$\$, that isotope effects are greatest when the proton is half-transferred in the transition state), by the possibility of secondary isotope effects (e.g., the presence of a β deuterium or tritium may cause the leaving group to depart more slowly), and by the possibility of tunneling.⁶⁴ Other isotope-effect studies have involved labeled α or β carbon, labeled α hydrogen, or labeled base.⁵⁸

Another way to study the position of a given reaction on the spectrum involves the use of β -aryl substitution. Since a positive Hammett ρ value is an indication of a negatively charged transition state, the ρ value for substituted β -aryl groups should increase as a reaction moves from E1- to E1cB-like along the spectrum. This has been shown to be the case in a number of studies;⁶⁵ for example, ρ values of $\text{ArCH}_2\text{CH}_2\text{X}$ increase as the leaving-group ability of X decreases. A typical set of ρ values was X = I, 2.07; Br, 2.14; Cl, 2.61; SMe_2^+ , 2.75; F, 3.12.⁶⁶ As we have seen, decreasing leaving-group ability correlates with increasing E1cB character.

Still another method measures volumes of activation.⁶⁷ These are negative for E2 and positive for E1cB mechanisms. Measurement of the activation volume therefore provides a continuous scale for deciding just where a reaction lies on the spectrum.

The E2C Mechanism⁶⁸

Certain alkyl halides and tosylates undergo E2 eliminations faster when treated with such weak bases as Cl^- in polar aprotic solvents or PhS^- than with the usual E2 strong bases, such as RO^- in ROH.⁶⁹ In order to explain these results, Parker

⁶³There is controversy as to whether such an effect has been established in this reaction: See Cockerill, A.F. *J. Chem. Soc. B* **1967**, 964; Blackwell, L.F. *J. Chem. Soc. Perkin Trans. 2* **1976**, 488.

and co-workers proposed⁷⁰ that there is a spectrum⁷¹ of E2 transition states in which the base can interact in the transition state with the α carbon, as well as with the β hydrogen. At one end of this spectrum is

a mechanism (called E2C) in which, in the transition state, the base interacts mainly with the carbon. The E2C mechanism is characterized by strong nucleophiles that are weak bases. At the other extreme is the normal E2 mechanism, here called E2H to distinguish it from E2C, characterized by strong bases. Transition state **17** represents a transition state between these extremes. Additional evidence⁷² for the E2C mechanism is derived from Brønsted equation considerations (p. 373), from substrate effects, from isotope effects, and from the effects of solvents on rates.

However, the E2C mechanism has been criticized, and it has been contended that all the experimental results can be explained by the normal E2 mechanism.⁷³ McLennan has suggested that the transition state is that shown as **18**.⁷⁴ An ion-pair mechanism has also been proposed.⁷⁵ Although the actual mechanisms involved may be a matter of controversy, there is no doubt that a class of elimination reactions exists that is characterized by second-order attack by weak bases.⁷⁶ These reactions also have the following general characteristics:⁷⁷ (1) they are favored by good leaving groups; (2) they are favored by polar aprotic solvents;

(3) the reactivity order is tertiary > secondary > primary, the opposite of the normal E2 order (p. 1503); (4) the elimination is always anti- (syn-elimination is not found), but in cyclohexyl systems, a diequatorial anti-elimination is about as favorable as a diaxial anti-elimination (unlike the normal E2 reaction, p. 1481); (5) they follow Zaitsev's rule (see below), where this does not conflict with the requirement for anti-elimination.

Regiochemistry of the Double Bond

With some substrates, a β hydrogen is present on only one carbon and (barring rearrangements) there is no doubt as to the identity of the product. For example, $\text{PhCH}_2\text{CH}_2\text{Br}$ can give only $\text{PhCH}=\text{CH}_2$. However, in many other cases two or three alkenyl products are possible. In the simplest such case, a *sec*-butyl compound can give either 1- or 2-butene. There are a number of rules that enable us to predict, in many instances, which product will predominantly form.⁷⁸

1. No matter what the mechanism, a double bond does not go to a bridgehead carbon unless the ring sizes are large enough (Bredt's rule, see p. 229). This means, for example, not only that **19** gives only **20** and not **21** (indeed **21** is not a known compound), but also that **22** does not undergo elimination.

2. No matter what the mechanism, if there is a double bond ($\text{C}=\text{C}$ or $\text{C}=\text{O}$) or an aromatic ring already in the molecule that can be in conjugation with the new double bond, the conjugated product usually predominates, sometimes even when the stereochemistry is unfavorable (for an exception, see p. 1501).
3. In the E1 mechanism the leaving group is gone before the choice is made as to which direction the new double bond takes. Therefore the direction is determined almost entirely by the relative stabilities of the two (or three) possible alkenes. In such cases, *Zaitsev's rule*⁷⁹ operates. This rule states that *the double bond goes mainly toward the most highly substituted carbon*. That is, a *sec*-butyl compound gives more 2-butene than 1-butene, and 3-bromo-2,3-dimethylpentane gives more 2,3-dimethyl-2-pentene than either 3,4-dimethyl-2-pentene or 2-ethyl-3-methyl-1-butene. Thus Zaitsev's rule predicts that the alkene predominantly formed will be the one with the largest possible number of alkyl groups on the $\text{C}=\text{C}$ carbons, and in most cases this is what is found. From heat of combustion data (see p. 29) it is known that

⁷⁸For a review of orientation in cycloalkyl systems, see Hückel, W.; Hanack, M. *Angew. Chem. Int. Ed.* **1967**, *6*, 534.

⁷⁹Often given the German spelling: Saytzeff.

alkene stability increases with alkyl substitution, although just why this should be is a matter of conjecture. The most common explanation is hyperconjugation. For E1 eliminations, Zaitsev's rule governs the orientation whether the leaving group is neutral or positive, since, as already mentioned, the leaving group is not present when the choice of direction is made. This statement does not hold for E2 eliminations, and it may be mentioned here, for contrast with later results, that E1 elimination of $\text{Me}_2\text{CHCHMeSMe}_2^+$ gave 91% of the Zaitsev product and 9% of the other.⁸⁰ However, there are cases in which the leaving group affects the direction of the double bond in E1-eliminations.⁸¹ This may be attributed to ion pairs; that is, the leaving group is not completely gone when the hydrogen departs. Zaitsev's rule breaks down in cases where the non-Zaitsev product is more stable for steric reasons. For example, E1 or E1-like eliminations of 1,2-diphenyl-2-X-propanes $\text{PhMeCXCH}_2\text{Ph}$ were reported to give ~50% $\text{CH}_2=\text{CPhCH}_2\text{Ph}$, despite the fact that the double bond of the Zaitsev product ($\text{PhMeC}=\text{CHPh}$) is conjugated with two benzene rings.⁸²

4. For the anti E2 mechanism a trans β proton is necessary; if this is available in only one direction, that is the way the double bond will form. Because of the free rotation in acyclic systems (except where steric hindrance is great), this is a factor only in cyclic systems. Where trans β hydrogens are available on two or three carbons, two types of behavior are found, depending on substrate structure and the nature of the leaving group. Some compounds follow Zaitsev's rule and give predominant formation of the most highly substituted alkene, but others follow *Hofmann's rule: The double bond goes mainly toward the least highly substituted carbon.* although many exceptions are known, the following general statements can be made: In most cases, compounds containing uncharged nucleofuges (those that come off as negative ions) follow Zaitsev's rule, just as they do in E1 elimination, no matter what the structure of the substrate. However, elimination from compounds with charged nucleofuges, for example, NR_3^+ , SR_2^+ (those that come off as neutral molecules), follow Hofmann's rule if the substrate is acyclic,⁸³ but Zaitsev's rule if the leaving group is attached to a six-membered ring.⁸⁴

Much work has been devoted to searching for the reasons for the differences in orientation. Since Zaitsev orientation almost always gives the

⁸⁰de la Mare, P.B.D. *Prog. Stereochem.* **1954**, *1*, 112.

⁸²Ho, I.; Smith, J.G. *Tetrahedron* **1970**, *26*, 4277.

⁸³An example of an acyclic quaternary ammonium salt that follows Zaitsev's rule is found, in Feit, I.N.; Saunders, Jr., W.H. *J. Am. Chem. Soc.* **1970**, *92*, 5615.

⁸⁴For examples where Zaitsev's rule is followed with charged leaving groups in cyclohexyl systems, see Gent, B.B.; McKenna, J. *J. Chem. Soc.* **1959**, 137; Hughes, E.D.; Wilby, J. *J. Chem. Soc.* **1960**, 4094; Brownlee, T.H.; Saunders Jr., W.H. *Proc. Chem. Soc.* **1961**, 314; Booth, H.; Franklin, N.C.; Gidley, G.C. *J. Chem. Soc. C* **1968**, 1891. For a discussion of the possible reasons for this, see Saunders, Jr., W.H.; Cockerill, A.F. *Mechanisms of Elimination Reactions*, Wiley, NY, **1973**, pp. 192–193.

thermodynamically more stable isomer, what needs to be explained is why in some cases the less stable Hofmann product predominates. Three explanations have been offered for the change in orientation in acyclic systems with a change from uncharged to charged nucleofuges. The first of these, by Hughes and Ingold,⁸⁵ is that Hofmann orientation is caused by the fact that the acidity of the β hydrogen is decreased by the presence of the electron-donating alkyl groups. For example, under E2 conditions $\text{Me}_2\text{CHCHMeSMe}_2^+$ gives more of the Hofmann product; it is the more acidic hydrogen that is removed by the base.

Of course, the CH_3 hydrogens would still be more acidic than the Me_2CH hydrogen even if a neutral leaving group were present, but the explanation of Hughes and Ingold is that acidity matters with charged and not with neutral leaving groups, because the charged groups exert a strong electron-withdrawing effect, making differences in acidity greater than they are with the less electron-withdrawing neutral groups.⁸⁵ The explanation of Bunnett⁸⁶ is similar. According to this, the change to a positive leaving group causes the mechanism to shift toward the E1cB end of the spectrum, where there is more C–H bond breaking in the rate-determining step and where, consequently, acidity is more important. In this view, when there is a neutral leaving group, the mechanism is more E1-like, C–X bond breaking is more important, and alkene stability determines the direction of the new double bond. The third explanation, by H.C. Brown, is completely different. In this picture, field effects are unimportant, and the difference in orientation is largely a steric effect caused by the fact that charged groups are usually larger than neutral ones. A CH_3 group is more open to attack than a CHR_2 group and a CHR_2 group is still less easily attacked. Of course, these considerations also apply when the leaving group is neutral, but, according to Brown, they are much less important here because the neutral groups are smaller and do not block access to the hydrogens as much. Brown showed that Hofmann elimination increases with the size of the leaving group. Thus the percentage of 1-ene obtained from $\text{CH}_3\text{CH}_2\text{CH}_2\text{CHXCH}_3$ was as follows (X listed in order of increasing size): Br, 31%; I, 30%; OTs, 48%; SMe_2^+ , 87%; SO_2Me , 89%;

⁸⁵For summaries of this position, see Ingold, C.K. *Proc. Chem. Soc.* **1962**, 265; Banthorpe, D.V.; Hughes, E.D.; Ingold, C.K. *J. Chem. Soc.* **1960**, 4054.

⁸⁶Bunnett, J.F. *Surv. Prog. Chem.* **1969**, 5, 53.

NMe_3^+ , 98%.⁸⁷ Hofmann elimination was also shown to increase with increase in bulk of the substrate.⁸⁸ With large enough compounds, Hofmann orientation can be obtained even with halides, for example, *tert*-amyl bromide gave 89% of the Hofmann product. Even those who believe in the acidity explanations concede that these steric factors operate in extreme cases.⁸⁹

There is one series of results incompatible with the steric explanation E2 elimination from the four 2-halopentanes gave the following percentages of 1-pentene: F, 83%; Cl, 37%; Br, 25%; I, 20%.⁹⁰ The same order was found for the four-2-halohexanes.⁹¹ Although there is some doubt about the relative steric requirements of Br, Cl, and I, there is no doubt that F is the smallest of the halogens, and if the steric explanation were the only valid one, the fluoroalkanes could not give predominant Hofmann orientation. Another result that argues against the steric explanation is the effect of changing the nature of the base. An experiment in which the effective size of the base was kept constant while its basicity was increased (by using as bases a series of $\text{XC}_6\text{H}_4\text{O}^-$ ions) showed that the percentage of Hofmann elimination increased with increasing base strength, although the size of the base did not change.⁹² These results are in accord with the explanation of Bunnett, since an increase in base strength moves an E2 reaction closer to the E1cB end of the spectrum. In further experiments, a large series of bases of different kinds was shown to obey linear free-energy relationships between basicity and percentage of Hofmann elimination,⁹³ although certain very large bases (e.g., 2,6-di-*tert*-butyl-phenoxide) did not obey the relationships, steric effects becoming important in these cases. How large the base must be before steric effects are observed depends on the pattern of alkyl substitution in the substrate, but not on the nucleofuge.⁹⁴ One further result may be noted. In the gas phase, elimination of H and BrH^+ or H and ClH^+ using Me_3N as the base predominantly followed Hofmann's rule,⁹⁵ although BrH^+ and ClH^+ are not very large.

- Only a few investigations on the orientation of syn E2 eliminations have been carried out, but these show that Hofmann orientation is greatly favored over Zaitsev.⁹⁶
- In the E1cB mechanism the question of orientation seldom arises because the mechanism is generally found only where there is an electron-withdrawing group in the β position, and that is where the double bond goes.
- As already mentioned, E2C reactions show a strong preference for Zaitsev orientation.⁹⁷ In some cases, this can be put to preparative use. For example, the compound $\text{PhCH}_2\text{CHOTsCHMe}_2$ gave $\sim 98\%$ $\text{PhCH}=\text{CHCHMe}_2$ under the usual E2 reaction conditions (*t*-BuOK in *t*-BuOH). In this case, the double bond goes to the side with more hydrogens because on that side it will be able to conjugate with the benzene ring. However, with the weak base $\text{Bu}_4\text{N}^+ \text{Br}^-$ in acetone the Zaitsev product $\text{PhCH}_2\text{CH}=\text{CMe}_2$ was formed in 90% yield.⁹⁸

Stereochemistry of the Double Bond

When elimination takes place on a compound of the form $\text{CH}_3\text{-CABX}$ or CHAB-CGGX , the new alkene does not have cis-trans isomerism, but for compounds of the form CHEG-CABX (E and G *not* H) (**23**) and $\text{CH}_2\text{E-CABX}$ (**24**), cis and trans isomers are possible. When the anti E2 mechanism is in operation, **23** gives the isomer

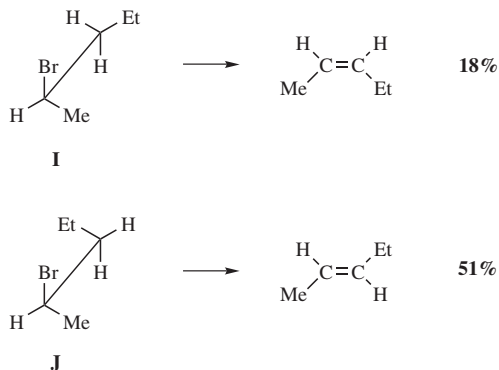

arising from trans orientation of X and H and, as we have seen before (p. 1478), an erythro compound gives the cis alkene and a threo compound the trans. For **24**, two conformations are possible for the transition state; these lead to different isomers and often both are obtained. However, the one that predominates is often determined by an eclipsing effect.⁹⁹ For example, Zaitsev elimination from 2-bromopentane can occur as follows:

⁹⁶Sicher, J.; Svoboda, M.; Pánková, M.; Závada, J. *Collect. Czech. Chem. Commun.* **1971**, *36*, 3633; Bailey, D.S.; Saunders, Jr., W.H. *J. Am. Chem. Soc.* **1970**, *92*, 6904.

In conformation **I**, the ethyl group is between Br and Me, while in **J** it is between Br and H. This means that **J** is more stable, and most of the elimination should occur from this conformation. This is indeed what happens, and 51% of the trans isomer is formed (with KOEt) compared to 18% of the cis (the rest is the Hofmann product).¹⁰⁰ These effects become larger with increasing size of A, B, and E.

However, eclipsing effects are not the only factors that affect the cis/trans ratio in anti E2 eliminations. Other factors are the nature of the leaving group, the base, the solvent, and the substrate. Not all these effects are completely understood.¹⁰¹

For E1 eliminations, if there is a free carbocation (**25**), it is free to rotate, and no matter what the geometry of the original compound, the more stable situation is the one where the larger of the D–E pair is opposite the smaller of the A–B pair and the corresponding alkene should form. If the carbocation is not completely free, then to that extent, E2-type products are formed. Similar considerations apply in E1cB eliminations.¹⁰²

REACTIVITY

In this section, we examine the effects of changes in the substrate, base, leaving group, and medium on (1) overall reactivity, (2) E1 versus E2 versus E1cB,¹⁰³ and (3) elimination versus substitution.

Effect of Substrate Structure

1. *Effect on Reactivity.* We refer to the carbon containing the nucleofuge (X) as the α carbon and to the carbon that loses the positive species as the β carbon. Groups attached to the α or β carbons can exert at least four kinds of influence:
 - a. They can stabilize or destabilize the incipient double bond (both α and β groups).
 - b. They can stabilize or destabilize an incipient negative charge, affecting the acidity of the proton (β groups only).
 - c. They can stabilize or destabilize an incipient positive charge (α groups only).
 - d. They can exert steric effects (e.g., eclipsing effects) (both α and β groups).

Effects a and d can apply in all three mechanisms, although steric effects are greatest for the E2 mechanism. Effect b does not apply in the E1 mechanism, and effect c does not apply in the E1cB mechanism. Groups, such as Ar and C=C, increase the rate by any mechanism, except perhaps when formation of the C=C bond is not the rate-determining step, whether they are α or β (effect a). Electron-withdrawing groups increase the acidity when in the β position, but have little effect in the α position unless they also conjugate with the double bond. Thus Br, Cl, CN, Ts, NO₂, CN, and SR in the β position all increase the rate of E2 eliminations.

2. *Effect on E1 versus E2 versus E1cB.* The α alkyl and α aryl groups stabilize the carbocation character of the transition state, shifting the spectrum toward the E1 end. β alkyl groups also shift the mechanism toward E1, since they *decrease* the acidity of the hydrogen. However, β aryl groups shift the mechanism the other way (toward E1cB) by stabilizing the carbanion. Indeed, as we have seen (p. \$\$\$), all electron-withdrawing groups in the β position shift the mechanism toward E1cB.¹⁰⁴ α alkyl groups also increase the extent of elimination with weak bases (E2C reactions).
3. *Effect on Elimination versus Substitution.* Under second-order conditions, a branching increases elimination, to the point where tertiary substrates undergo few S_N2 reactions, as we saw in Chapter 10. For example, Table 17.2 shows results on some simple alkyl bromides. Similar results were obtained with SMe₂⁺ as the leaving group.¹⁰⁵ Two reasons can be presented for this trend. One is statistical: As a branching increases, there are usually more hydrogens for the base to attack. The other is that a branching presents steric hindrance to attack of the base at the carbon. Under first-order conditions, increased a branching also increases the amount of elimination (E1 vs. S_N1), although not

¹⁰⁴For a review of eliminations with COOH, COOR, CONH₂, and CN groups in the β position, see Butskus, P.F.; Denis, G.I. *Russ. Chem. Rev.* **1966**, 35, 839.

TABLE 17.2. The Effect of α and β Branching on the Rate of E2 Elimination and the Amount of Alkene Formed^a

Substrate	Temperature, °C	Alkene, %	Rate $\times 10^5$ of E2 Reaction	Reference
CH ₃ CH ₂ Br	55	0.9	1.6	108
(CH ₃) ₂ CHBr	24	80.3	0.237	109
(CH ₃) ₃ CBr	25	97	4.17	107
CH ₃ CH ₂ CH ₂ Br	55	8.9	5.3	105
(CH ₃) ₂ CHCH ₂ Br	55	59.5	8.5	105

^aThe reactions were between the alkyl bromide and ⁻OEt. The rate for isopropyl bromide was actually greater than that for ethyl bromide, if the temperature difference is considered. Neopentyl bromide, the next compound in the β -branching series, cannot be compared because it has no β -hydrogen and cannot give an elimination product without rearrangement.

so much, and usually the substitution product predominates. For example, solvolysis of *tert*-butyl bromide gave only 19% elimination¹⁰⁶ (cf. with Table 17.2). β Branching also increases the amount of E2 elimination with respect to S_N2 substitution (Table 17.2), not because elimination is faster, but because the S_N2 mechanism is so greatly slowed (p. 478). Under first-order conditions too, β branching favors elimination over substitution, probably for steric reasons.¹⁰⁷ However, E2 eliminations from compounds with charged leaving groups are slowed by β branching. This is related to Hofmann's rule (p. 1498). Electron-withdrawing groups in the β position not only increase the rate of E2 eliminations and shift the mechanisms toward the E1cB end of the spectrum, but also increase the extent of elimination as opposed to substitution.

Effect of the Attacking Base

- 1. Effect on E1 versus E2 versus E1cB.** In the E1 mechanism, an external base is generally not required: The solvent acts as the base. Hence, when external bases are added, the mechanism is shifted toward E2. Stronger bases and higher base concentrations cause the mechanism to move toward the E1cB end of the E1-E2-E1cB spectrum.¹¹⁰ However, weak bases in polar aprotic solvents can also be effective in elimination reactions with certain substrates (the E2C reaction). Normal E2 elimination has been accomplished with the following bases:¹¹¹ H₂O, NR₃, ⁻OH, ⁻OAc, ⁻OR, ⁻OAr, ⁻NH₂, CO₃²⁻,

¹¹¹This list is from Banthorpe, D.V. *Elimination Reactions*; Elsevier, NY, **1963**, p. 4.

LiAlH_4 , I^- , CN^- , and organic bases. However, the only bases of preparative importance in the normal E2 reaction are OH^- , OR^- , and NH_2^- , usually in the conjugate acid as solvent, and certain amines. Weak bases effective in the E2C reaction are Cl^- , Br^- , F^- , OAc^- , and RS^- . These bases are often used in the form of their R_4N^+ salts.

2. *Effect on Elimination versus Substitution.* Strong bases not only benefit E2 as against E1, but also benefit elimination as against substitution. With a high concentration of strong base in a non-ionizing solvent, bimolecular mechanisms are favored and E2 predominates over $\text{S}_{\text{N}}2$. At low base concentrations, or in the absence of base altogether, in ionizing solvents, unimolecular mechanisms are favored, and the $\text{S}_{\text{N}}1$ mechanism predominates over the E1. In Chapter 10, it was pointed out that some species are strong nucleophiles, but weak bases (p. 490). The use of these obviously favors substitution, except that, as we have seen, elimination can predominate if polar aprotic solvents are used. It has been shown for the base cyanide that in polar aprotic solvents, the less the base is encumbered by its counterion in an ion pair (i.e., the freer the base), the more substitution is favored at the expense of elimination.¹¹²

Effect of the Leaving Group

1. *Effect on Reactivity.* The leaving groups in elimination reactions are similar to those in nucleophilic substitution. The E2 eliminations have been performed with the following groups: NR_3^+ , PR_3^+ , SR_2^+ , OHR^+ , SO_2R , OSO_2R , OCOR , OOH , OOR , NO_2 ,¹¹³ F, Cl, Br, I, and CN (not OH_2^+). The E1 eliminations have been carried out with: NR_3^+ , SR_2^+ , OH_2^+ , OHR^+ , OSO_2R , OCOR , Cl, Br, I, and N_2^+ .¹¹⁴ However, the major leaving groups for preparative purposes are OH_2^+ (always by E1) and Cl, Br, I, and NR_3^+ (usually by E2).
2. *Effect on E1 versus E2 versus E1cB.* Better leaving groups shift the mechanism toward the E1 end of the spectrum, since they make ionization easier. This effect has been studied in various ways. One way already mentioned was a study of ρ values (p. 1495). Poor leaving groups and positively charged leaving groups shift the mechanism toward the E1cB end of the spectrum because the strong electron-withdrawing field effects increase the acidity of the β hydrogen.¹¹⁵ The E2C reaction is favored by good leaving groups.
3. *Effect on Elimination versus Substitution.* As we have already seen (p. 1487), for first-order reactions the leaving group has nothing to do with the

¹¹⁴These lists are from Banthorpe, D.V. *Elimination Reactions*, Elsevier, NY, **1963**, pp. 4, 7.

¹¹⁵For a discussion of leaving-group ability, see Stirling, C.J.M. *Acc. Chem. Res.* **1979**, *12*, 198. See also, Varma, M.; Stirling, C.J.M. *J. Chem. Soc., Chem. Commun.* **1981**, 553.

competition between elimination and substitution, since it is gone before the decision is made as to which path to take. However, where ion pairs are involved, this is not true, and results have been found where the nature of the leaving group does affect the product.¹¹⁶ In second-order reactions, the elimination/substitution ratio is not greatly dependent on a halide leaving group, although there is a slight increase in elimination in the order $I > Br > Cl$. When OTs is the leaving group, there is usually much more substitution. For example, $n\text{-C}_{18}\text{H}_{37}\text{Br}$ treated with $t\text{-BuOK}$ gave 85% elimination, while $n\text{-C}_{18}\text{H}_{37}\text{OTs}$ gave, under the same conditions, 99% substitution.¹¹⁷ On the other hand, positively charged leaving groups increase the amount of elimination.

Effect of the Medium

1. *Effect of Solvent on E1 versus E2 versus E1cB.* With any reaction a more polar environment enhances the rate of mechanisms that involve ionic intermediates. For neutral leaving groups, it is expected that E1 and E1cB mechanisms will be aided by increasing polarity of solvent and by increasing ionic strength. With certain substrates, polar aprotic solvents promote elimination with weak bases (the E2C reaction).
2. *Effect of Solvent on Elimination versus Substitution.* Increasing polarity of solvent favors S_N2 reactions at the expense of E2. In the classical example, alcoholic KOH is used to effect elimination, while the more polar aqueous KOH is used for substitution. Charge-dispersal discussions, similar to those on p. 503,¹¹⁸ only partially explain this. In most solvents, S_N1 reactions are favored over E1. The E1 reactions compete best in polar solvents that are poor nucleophiles, especially dipolar aprotic solvents.¹¹⁹ A study made in the gas phase, where there is no solvent, has shown that when 1-bromopropane reacts with MeO^- only elimination takes place (no substitution) even with this primary substrate.¹²⁰
3. *Effect of Temperature.* Elimination is favored over substitution by increasing temperature, whether the mechanism is first or second order.¹²¹ The reason is that the activation energies of eliminations are higher than those of substitutions (because eliminations have greater changes in bonding).

MECHANISMS AND ORIENTATION IN PYROLYTIC ELIMINATIONS

Mechanisms¹²²

Several types of compound undergo elimination on heating, with no other reagent present. Reactions of this type are often run in the gas phase. The mechanisms are obviously different from those already discussed, since all those require a base (which may be the solvent) in one of the steps, and there is no base or solvent present in pyrolytic elimination. Two mechanisms have been found to operate. One involves a cyclic transition state, which may be four, five, or six membered. Examples of each size are

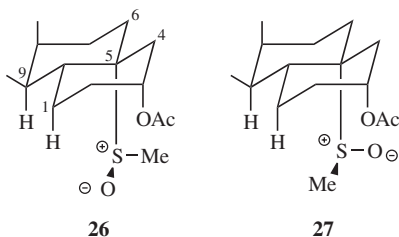

In this mechanism, the two groups leave at about the same time and bond to each other as they are doing so. The designation is E^i in the Ingold terminology and *cyclo-D_ED_NA_n* in the IUPAC system. The elimination must be syn and, for the four- and five-membered transition states, the four or five atoms making up the ring must be coplanar. Coplanarity is not required for the six-membered transition state, since there is room for the outside atoms when the leaving atoms are staggered.

¹²²For reviews, see Taylor, R., in Patai, S. *The Chemistry of Functional Groups, Supplement B*, pt. 2, Wiley, NY, 1979, pp. 860–914; Smith, G.G.; Kelly, F.W. *Prog. Phys. Org. Chem.* 1971, 8, 75, pp. 76–143, 207–234; in Bamford, C.H.; Tipper, C.F.H. *Comprehensive Chemical Kinetics*, Vol. 5, Elsevier, NY, 1972, the articles by Swinbourne, E.S. pp. 149–233 (pp. 158–188), and by Richardson, W.H.; O’Neal, H.E. pp. 381–565 (pp. 381–446); Maccoll, A. *Adv. Phys. Org. Chem.* 1965, 3, 91. For reviews of mechanisms in pyrolytic eliminations of halides, see Egger, K.W.; Cocks, A.T., in Patai’s *The Chemistry of the Carbon-Halogen Bond*, pt. 2, Wiley, NY, 1973, pp. 677–745; Maccoll, A. *Chem. Rev.* 1969, 69, 33.

As in the E2 mechanism, it is not necessary that the C–H and C–X bond be equally broken in the transition state. In fact, there is also a spectrum of mechanisms here, ranging from a mechanism in which C–X bond breaking is a good deal more advanced than C–H bond breaking to one in which the extent of bond breaking is virtually identical for the two bonds. Evidence for the existence of the Eⁱ mechanism is

1. The kinetics are first order, so only one molecule of the substrate is involved in the reaction (i.e., if one molecule attacked another, the kinetics would be second order in substrate).¹²³
2. Free-radical inhibitors do not slow the reactions, so no free-radical mechanism is involved.¹²⁴
3. The mechanism predicts exclusive syn elimination, and this behavior has been found in many cases.¹²⁵ The evidence is inverse to that for the anti E2 mechanism and generally involves the following facts: (1) an erythro isomer gives a trans alkene and a threo isomer gives a cis alkene; (2) the reaction takes place only when a cis β hydrogen is available; (3) if, in a cyclic compound, a cis hydrogen is available on only one side, the elimination goes in that direction. Another piece of evidence involves a pair of steroid molecules. In 3β-acetoxy-(R)-5α-methylsulfinylcholestane (**26** shows rings A and B of this compound) and in 3β-acetoxy-(S)-5α-methylsulfinylcholestane (**27**: rings A and B), the *only* difference is the configuration of

oxygen and methyl about the sulfur. Yet pyrolysis of **26** gave only elimination to the 4-side (86% 4-ene), while **27** gave predominant elimination to the 6-side (65% 5-ene and 20% 4-ene).¹²⁶ Models show that interference from the 1- and 9-hydrogens causes the two groups on the sulfur to lie *in front of it* with respect to the rings, rather than behind it. Since the sulfur is chiral, this

¹²³O'Connor, G.L.; Nace, H.R. *J. Am. Chem. Soc.* **1953**, *75*, 2118.

¹²⁴Barton, D.H.R.; Head, A.J.; Williams, R.J. *J. Chem. Soc.* **1953**, 1715.

¹²⁵In a few instances anti or nonstereoselective elimination has been found; this behavior is generally ascribed to the intervention of other mechanisms. For example, see Bordwell, F.G.; Landis, P.S. *J. Am. Chem. Soc.* **1958**, *80*, 2450, 6383; Briggs, W.S.; Djerassi, C. *J. Org. Chem.* **1968**, *33*, 1625; Smitsman, E.E.; Li, J.P.; Creese, M.W. *J. Org. Chem.* **1970**, *35*, 1352.

¹²⁶Jones, D.N.; Saeed, M.A. *Proc. Chem. Soc.* **1964**, 81. See also, Goldberg, S.I.; Sahli, M.S. *J. Org. Chem.* **1967**, *32*, 2059.

- means that in **26** the oxygen is near the 4-hydrogen, while in **27** it is near the 6-hydrogen. This experiment is compatible only with syn-elimination.¹²⁷
4. The ¹⁴C isotope effects for the Cope elimination (**17-9**) show that both the C-H and C-N bonds have been extensively broken in the transition state.¹²⁸
 5. Some of these reactions have been shown to exhibit negative entropies of activation, indicating that the molecules are more restricted in geometry in the transition state than they are in the starting compound.

Where a pyrolytic elimination lies on the mechanistic spectrum seems to depend mostly on the leaving group. When this is halogen, all available evidence suggests that in the transition state the C-X bond is cleaved to a much greater extent than the C-H bond, that is, there is a considerable amount of carbocation character in the transition state. This is in accord with the fact that a completely nonpolar four-membered cyclic transition state violates the Woodward-Hoffmann rules (see the similar case of **15-63**). Evidence for the carbocation-like character of the transition state when halide is the leaving group is that relative rates are in the order $I > Br > Cl$ ¹²⁹ (see p. 496), and that the effects of substituents on reaction rates are in accord with such a transition state.¹³⁰ Rate ratios for pyrolysis of some alkyl bromides at 320°C were ethyl bromide, 1; isopropyl bromide, 280; *tert*-butyl bromide, 78,000. Also, α -phenylethyl bromide had about the same rate as *tert*-butyl bromide. On the other hand, β -phenylethyl bromide was only slightly faster than ethyl bromide.¹³¹ This indicates that C-Br cleavage was much more important in the transition state than C-H cleavage, since the incipient carbocation was stabilized by a alkyl and α -aryl substitution, while there was no incipient carbanion to be stabilized by β -aryl substitution. These substituent effects, as well as those for other groups, are very similar to the effects found for the S_N1 mechanism and thus in very good accord with a carbocation-like transition state.

For carboxylic esters, the rate ratios were much smaller,¹³² although still in the same order, so that this reaction is closer to a pure Eⁱ mechanism, although the transition state still has some carbocationic character. Other evidence for a greater initial C-O cleavage with carboxylic esters is that a series of 1-arylethyl acetates followed σ^+ rather than σ , showing carbocationic character at the 1 position.¹³³

Perkin Trans. 2* **1990**, 2187.

The extent of E1 character in the transition state increases in the following order of ester types: acetate < phenylacetate < benzoate < carbamate < carbonate.¹³⁴ Cleavage of xanthates (**17-5**), cleavage of sulfoxides (**17-12**), the Cope reaction (**17-9**), and reaction **17-8** are probably very close to straight Eⁱ mechanisms.¹³⁵

The second type of pyrolysis mechanism is completely different and involves free radicals. Initiation occurs by pyrolytic homolytic cleavage. The remaining steps may vary, and a few are shown

Free-radical mechanisms are mostly found in pyrolyses of polyhalides and of primary monohalides,¹³⁶ although they also have been postulated in pyrolysis of certain carboxylic esters.¹³⁷ β -Elimination of tosyl radicals is known.¹³⁸ Much less is known about these mechanisms and we will not consider them further. Free-radical eliminations in solution are also known, but are rare.¹³⁹

Orientation in Pyrolytic Eliminations

As in the E1-E2-E1cB mechanistic spectrum, Bredt's rule applies; and if a double bond is present, a conjugated system will be preferred, if sterically possible. Apart from these considerations, the following statements can be made for Eⁱ eliminations:

1. In the absence of considerations mentioned below, orientation is statistical and is determined by the number of β hydrogens available (therefore *Hofmann's rule* is followed). For example, *sec*-butyl acetate gives 55–62%

1-butene and 38–45% 2-butene,¹⁴⁰ which is close to the 3:2 distribution predicted by the number of hydrogens available.¹⁴¹

2. A cis β hydrogen is required. Therefore in cyclic systems, if there is a cis hydrogen on only one side, the double bond will go that way. However, when there is a six-membered transition state, this does not necessarily mean that the leaving groups must be cis to each other, since such transition states need not be completely coplanar. If the leaving group is axial, then the hydrogen obviously must be equatorial (and consequently cis to the leaving group), since the transition state cannot be realized when the groups are both axial. But if the leaving group is equatorial, it can form a transition state with a β hydrogen that is either axial (hence, cis) or equatorial (hence, trans). Thus **28**, in which the leaving group is most likely axial, does not form a double bond in the

direction of the carboxyl group, even although that would be conjugated, because there is no equatorial hydrogen on that side. Instead it gives 100% **29**.¹⁴² On the other hand, **30**, with an equatorial leaving group, gives ~50% of each alkene, even although, for elimination to the 1-ene, the leaving group must go off with a trans hydrogen.¹⁴³

3. In some cases, especially with cyclic compounds, the more stable alkene forms and Zaitsev's rule applies. For example, menthyl acetate gives 35% of the Hofmann product and 65% of the Zaitsev, even although a cis β hydrogen is present on both sides and the statistical distribution is the other way. A similar result was found for the pyrolysis of menthyl chloride.¹⁴⁴
4. There are also steric effects. In some cases, the direction of elimination is determined by the need to minimize steric interactions in the transition state or to relieve steric interactions in the ground state.

1,4 Conjugate Eliminations¹⁴⁵

1,4-Eliminations of the type

are much rarer than conjugate additions (Chapter 15), but some examples are known.¹⁴⁶ One such is¹⁴⁷

**REACTIONS**

First, we consider reactions in which a C=C or a C≡C bond is formed. From a synthetic point of view, the most important reactions for the formation of double bonds are **17-1** (usually by an E1 mechanism), **17-7**, **17-13**, and **17-22** (usually by an E2 mechanism), and **17-4**, **17-5**, and **17-9** (usually by an Eⁱ mechanism). The only synthetically important method for the formation of triple bonds is **17-13**.¹⁴⁸ In the second section, we treat reactions in which C≡N bonds and C=N bonds are formed, and then eliminations that give C=O bonds and diazoalkanes. Finally, we discuss extrusion reactions.

REACTIONS IN WHICH C=C AND C≡C BONDS ARE FORMED**A. Reactions in which Hydrogen Is Removed from One Side**

In **17-1–17-6**, the other leaving atom is oxygen. In **17-7–17-11**, it is nitrogen. For reactions in which hydrogen is removed from both sides, see **19-1–19-6**.

17-1 Dehydration of Alcohols

Hydro-hydroxy-elimination

Dehydration of alcohols can be accomplished in several ways. Both H_2SO_4 and H_3PO_4 are common reagents, but in many cases these lead to rearrangement products and to ether formation (**10-12**). If the alcohol can be evaporated, vapor-phase elimination over Al_2O_3 is an excellent method since side reactions are greatly reduced. This method has even been applied to such high-molecular-weight alcohols as 1-dodecanol.¹⁴⁹ Other metallic oxides (e.g., Cr_2O_3 , TiO_2 , WO_3) have also been used, as have been sulfides, other metallic salts, and zeolites. The presence of an electron-withdrawing group usually facilitates elimination of water, as in the aldol condensation (**16-35**). 2-Nitroalcohols, for example, give conjugated nitro compounds when heated with zeolite Y-Y.¹⁵⁰ Treating a 4-hydroxy lactam with DMAP (*N,N*-dimethylaminopyridine) and Boc anhydride leads to the conjugated lactam.¹⁵¹ Elimination of serine derivatives to α -alkylidene amino acid derivatives was accomplished with $(\text{EtO})_2\text{POCl}$.¹⁵² Another method of avoiding side reactions is the conversion of alcohols to esters, and the pyrolysis of these (**17-4-17-6**). The ease of dehydration increases with α branching, and tertiary alcohols are dehydrated so easily with only a trace of acid that it sometimes happens even when the investigator desires otherwise. It may also be recalled that the initial alcohol products of many base-catalyzed condensations dehydrate spontaneously (Chapter 16) because the new double bond can be in conjugation with one already there. Many other dehydrating agents¹⁵³ have been used on occasion: P_2O_5 , I_2 , ZnCl_2 , $\text{Ph}_3\text{BiBr}_2/\text{I}_2$,¹⁵⁴ PPh_3-I_2 ,¹⁵⁵ BF_3 -etherate, DMSO, $\text{SiO}_2-\text{Cl}/\text{Me}_3\text{SiCl}$,¹⁵⁶ KHSO_4 , anhydrous CuSO_4 , and phthalic anhydride, among others. Secondary and tertiary alcohols can also be dehydrated, without rearrangements, simply on refluxing in HMPA.¹⁵⁷ With nearly all reagents, dehydration follows Zaitsev's rule.

¹⁴⁹For example, see Spitzin, V.I.; Michailenko, I.E.; Pirogowa, G.N. *J. Prakt. Chem.* **1964**, [4] 25, 160; Bertsch, H.; Greiner, A.; Kretzschmar, G.; Falk, F. *J. Prakt. Chem.* **1964**, [4] 25, 184.

An exception involves the passage of hot alcohol vapors over thorium oxide at 350–450°C, under which conditions Hofmann's rule is followed,¹⁵⁸ and the mechanism is probably different. Cyclobutanol derivatives can be opened in the presence of a palladium catalyst. 2-Phenylbicyclo[3.2.0]octan-2-ol, for example, reacted with a catalytic amount of palladium acetate in the presence of pyridine and oxygen to give phenyl methylenecyclohexane ketone.¹⁵⁹

Transition metals can induce the dehydration of certain alcohols. β -Hydroxy ketones are converted to conjugated ketones by treatment with CeCl_3 and NaI .¹⁶⁰ In the presence of a palladium complex, alkyl cyclopropanols undergo a dehydration reaction to give a conjugated ketone.¹⁶¹ A δ -hydroxy- α,β -unsaturated aldehyde was converted to a dienyl aldehyde with a hafnium catalyst.¹⁶² β -Hydroxy esters are converted to conjugated esters when treated with 2 equivalents of SmI_2 .¹⁶³ The reaction of a β -hydroxy nitrile with methylmagnesium chloride¹⁶⁴ or with MgO ¹⁶⁵ leads to a conjugated nitrile. In another variation of the dehydration reaction, vicinal bromohydrins are converted to alkenes upon treatment with In , InCl_3 , and a palladium catalyst.¹⁶⁶ Chlorohydrins react similarly when treated with samarium, and then diiodomethane.¹⁶⁷

Carboxylic acids can be dehydrated by pyrolysis, the product being a ketene:

Ketene itself is commercially prepared in this manner. Carboxylic acids have also been converted to ketenes by treatment with certain reagents, among them TsCl ,¹⁶⁸ dicyclohexylcarbodiimide,¹⁶⁹ and 1-methyl-2-chloropyridinium iodide (*Mukaiyama's reagent*).¹⁷⁰ Analogously, amides can be dehydrated with P_2O_5 , pyridine,

and Al_2O_3 to give ketenimines:¹⁷¹

There is no way in which dehydration of alcohols can be used to prepare triple bonds: *gem*-diols and vinylic alcohols are not normally stable compounds and *vic*-diols¹⁷² give either conjugated dienes or lose only 1 equivalent of water to give an aldehyde or ketone. Dienes can be prepared, however, by heating alkynyl alcohols with triphenyl phosphine.¹⁷³

When proton acids catalyze alcohol dehydration, the mechanism is E1.¹⁷⁴ The principal process involves conversion of ROH to ROH_2^+ and cleavage of the latter to R^+ and H_2O , although with some acids a secondary process probably involves conversion of the alcohol to an inorganic ester and ionization of *this* (illustrated for H_2SO_4):

Note that these mechanisms are the reverse of those involved in the acid-catalyzed hydration of double bonds (**15-3**), in accord with the principle of microscopic reversibility. With anhydrides (e.g., P_2O_5 , phthalic anhydride), as well as with some other reagents, such as HMPA,¹⁷⁵ it is likely that an ester is formed, and the leaving group is the conjugate base of the corresponding acid. In these cases, the mechanism can be E1 or E2. The mechanism with Al_2O_3 and other solid catalysts has been studied extensively, but is poorly understood.¹⁷⁶

Magnesium alkoxides (formed by $\text{ROH} + \text{Me}_2\text{Mg} \rightarrow \text{ROMgMe}$) have been decomposed thermally, by heating at 195–340°C to give the alkene, CH_4 , and MgO .¹⁷⁷ Syn-elimination is found and an Eⁱ mechanism is likely. Similar decomposition of aluminum and zinc alkoxides has also been accomplished.^{178,189}

See also, OS VII, 63; VIII, 306, 474. No attempt has been made to list alkene-forming dehydration reactions accompanying condensations or rearrangements.

17-2 Cleavage of Ethers to Alkenes

Hydro-alkoxy-elimination

Alkenes can be formed by the treatment of ethers with very strong bases, such as alkylsodium or alkylolithium¹⁷⁹ compounds, sodium amide,¹⁸⁰ or LDA,¹⁸¹ although there are side reactions with many of these reagents. The reaction is aided by electron-withdrawing groups in the β position, and, for example, $\text{EtOCH}_2\text{CH}(\text{COOEt})_2$ can be converted to $\text{CH}_2=\text{C}(\text{COOEt})_2$ without any base at all, but simply on heating.¹⁸² *tert*-Butyl ethers are cleaved more easily than others. Several mechanisms are possible. In many cases, the mechanism is probably E1cB or on the E1cB side of the mechanistic spectrum,¹⁸³ since the base required is so strong, but it has been shown (by the use of PhCD_2OEt) that PhCH_2OEt reacts by the five-membered Eⁱ mechanism.¹⁸⁴ Propargylic benzyl ethers are converted to conjugated dienes by heating with a ruthenium catalyst.¹⁸⁵

Ethers have also been converted to alkenes and alcohols by passing vapors over hot P_2O_5 or Al_2O_3 (this method is similar to **17-1**), but this is not a general reaction. Cyclic ethers, such as THF, react slowly with organolithium reagents with cleavage that produces a $\text{C}=\text{C}$ unit.¹⁸⁶ Fragmentation of 2,5-dihydrofuran with ethylmagnesium chloride and a chiral zirconium catalyst leads to a chiral, homoallylic alcohol.¹⁸⁷ However, acetals can be converted to enol ethers (**31**) in this manner.

¹⁸⁷Morken, J.P.; Didiuk, M.T.; Hoveyda, A.H. *J. Am. Chem. Soc.* **1993**, 115, 6997.

When ketals react with 2 equivalents of triisobutylaluminum, the product is a vinyl ether.¹⁸⁸

This can also be done at room temperature by treatment with trimethylsilyl triflate and a tertiary amine¹⁸⁹ or with Me₃SiI in the presence of hexamethyldisilazane.¹⁹⁰

Enol ethers can be pyrolyzed to alkenes and aldehydes in a manner similar to that of **17-4**

The rate of this reaction for R-O-CH=CH₂ increased in the order Et < *i*Pr < *t*-Bu.¹⁹¹ The mechanism is similar to that of **17-4**.

17-3 The Conversion of Epoxides and Episulfides to Alkenes

epi-Oxy-elimination

Epoxides can be converted to alkenes¹⁹² by treatment with triphenylphosphine¹⁹³ or triethyl phosphite P(OEt)₃.¹⁹⁴ The first step of the mechanism is nucleophilic substitution (**10-35**), followed by a four-center elimination. Since inversion accompanies the substitution, the overall elimination is anti, that is, if two groups A and C are cis in the epoxide, they will be trans in the alkene:

¹⁹³Wittig, G.; Haag, W. *Chem. Ber.* **1955**, 88, 1654.

¹⁹⁴Scott, C.B. *J. Org. Chem.* **1957**, 22, 1118.

Alternatively, the epoxide can be treated with lithium diphenylphosphide, Ph_2PLi , and the product quaternized with methyl iodide.¹⁹⁵ Alkenes have also been obtained from epoxides by reaction with a large number of reagents,¹⁹⁶ among them Li in THF,¹⁹⁷ TsOH and NaI ,¹⁹⁸ trimethylsilyl iodide,¹⁹⁹ PI_3 ,²⁰⁰ $\text{F}_3\text{COOH-NaI}$,²⁰¹ SmI_2 ,²⁰² $\text{Mo}(\text{CO})_6$, TpReO_3 , where Tp is a pyrazolyl borate,²⁰³ and the tungsten reagents mentioned in **17-18**. Some of these methods give syn elimination. Treatment of cyclooctane oxide with $\text{Ph}_3\text{P-OPPh}_3$ and NEt_3 gave cyclooctadiene.²⁰⁴ Sodium amalgam with a cobalt-salen complex converted epoxides to alkenes.²⁰⁵

Epoxides can be converted to allylic alcohols²⁰⁶ by treatment with several reagents, including *sec*-butyllithium,²⁰⁷ *tert*-butyldimethylsilyl iodide,²⁰⁸ and *iPr*₂N-Li-*t*-BuOK (the *LIDAKOR* reagent).²⁰⁹ Phenyllithium reacts with epoxides in the presence of lithium tetramethylpiperidide (LTMP) to give a trans alkene.²¹⁰ Sulfur ylids, such as $\text{Me}_2\text{S}=\text{CH}_2$, also convert epoxides to allylic alcohols.²¹¹ Bromomethyl epoxides react with $\text{InCl}_3/\text{NaBH}_4$ to give an allylic alcohol.²¹² α,β -Epoxy ketones are converted to conjugated ketones by treatment with NaI in acetone in the presence of Amberlyst 15,²¹³ or with 2.5 equivalents of SmI_2 .²¹⁴ Cyclic epoxides are converted to conjugated dienes by heating with $(\text{NMe}_2)_2\text{P}(=\text{O})\text{Cl}$ and H_2O .²¹⁵

When an optically active reagent is used, optically active allylic alcohols can be produced from achiral epoxides.²¹⁶ Sparteine and *sec*-butyllithium generate a chiral base that leads to formation of chiral allylic alcohols.²¹⁷ Chiral diamines react with organolithium reagents to produce chiral bases that convert epoxides to allylic alcohols with good enantioselectivity.²¹⁸ Chiral diamines with a mixture of LDA and DBU (p. 1132) give similar results.²¹⁹

Episulfides²²⁰ can be converted to alkenes.²²¹ However, in this case the elimination is syn, so the mechanism cannot be the same as that for conversion of epoxides. The phosphite attacks sulfur rather than carbon. Among other reagents that convert episulfides to alkenes are Bu_3SnH ,²²² certain rhodium complexes,²²³ LiAlH_4 ,²²⁴ (this compound behaves quite differently with epoxides, see **19-35**), and MeI .²²⁵ The reaction of $\text{H}_2\text{S/PPh}_3$ and MeReO_3 converts episulfides to alkenes.²²⁶ Episulfides can be converted to alkenes and sulfur monoxide simply by heating.²²⁷

Direct elimination of a carboxylic acid to an alkene has been accomplished by heating in the presence of palladium catalysts.²²⁸ Carboxylic esters in which the alkyl group has a β hydrogen can be pyrolyzed, most often in the gas phase, to give the corresponding acid and an alkene.²²⁹ No solvent is required. Since rearrangement and other side reactions are few, the reaction is synthetically very useful and is often carried out as an indirect method of accomplishing **17-1**. The yields are excellent and the workup is easy. Many alkenes have been prepared in this manner. For higher alkenes (above $\sim C_{10}$) a better method is to pyrolyze the alcohol in the presence of acetic anhydride.²³⁰

The mechanism is E^1 (see p. 1507). Lactones can be pyrolyzed to give unsaturated acids, provided that the six-membered transition state required for E^1 reactions is available (it is not available for five- and six-membered lactones, but it is for larger rings²³¹). Amides give a similar reaction, but require higher temperatures.

Allylic acetates give dienes when heated with certain palladium²³² or molybdenum²³³ compounds.

OS **III**, 30; **IV**, 746; **V**, 235; **IX**, 293.

17-5 The Chugaev Reaction

Methyl xanthates are prepared by treatment of alcohols with NaOH and CS_2 to give $\text{RO}-\text{C}(=\text{S})-\text{SNa}$, followed by treatment of this with methyl iodide.²³⁴ Pyrolysis of the xanthate to give the alkene, COS, and the thiol is called the *Chugaev reaction*.²³⁵ The reaction is thus, like **17-4**, an indirect method of accomplishing **17-2**. The temperatures required with xanthates are lower than with ordinary esters, which is advantageous because possible isomerization of the resulting alkene is minimized. The mechanism is E^1 , similar to that of **17-4**. For a time there was doubt as to which sulfur atom closed the ring, but now there is much evidence, including

the study of ^{34}S and ^{13}C isotope effects, to show that it is the C=S sulfur.²³⁶ In a structural variation of this reaction, heating a propargylic xanthate with 2,4,6-trimethylpyridinium trifluoromethyl sulfonate leads to formation of an alkene.²³⁷

The mechanism is thus exactly analogous to that of **17-5**.

OS **VII**, 139.

17-6 Decomposition of Other Esters

Hydro-tosyloxy-elimination

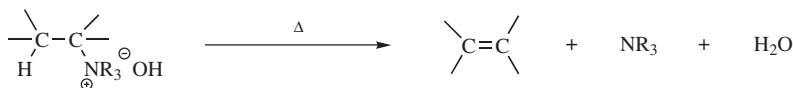

Several types of inorganic ester can be cleaved to alkenes by treatment with bases. Esters of sulfuric, sulfurous, and other acids undergo elimination in solution by E1 or E2 mechanisms, as do tosylates and other esters of sulfonic acids.²³⁸ It has been shown that bis(tetra-*n*-butylammonium) oxalate, $(\text{Bu}_4\text{N}^+)_2 (\text{COO}^-)_2$, is an excellent reagent for inducing tosylates to undergo elimination rather than substitution.²³⁹ Aryl sulfonates have also been cleaved without a base. Esters of 2-pyridinesulfonic acid and 8-quinolinesulfonic acid gave alkenes in high yields simply on heating, without a solvent.²⁴⁰ Phosphonate esters have been cleaved to alkenes by treatment with Lawesson's reagent.²⁴¹ Esters of PhSO_2OH and TsOH behaved similarly when heated in a dipolar aprotic solvent, such as Me_2SO or HMPA.²⁴²

Cleavage of quaternary ammonium hydroxides is the final step of the process known as *Hofmann exhaustive methylation or Hofmann degradation*.²⁴³ In the first step, a primary, secondary, or tertiary amine is treated with enough methyl iodide to convert it to the quaternary ammonium iodide (**10-31**). In the second step, the iodide is converted to the hydroxide by treatment with silver oxide. In the cleavage step, an aqueous or alcoholic solution of the hydroxide is distilled, often under reduced pressure. The decomposition generally takes place at a temperature between 100 and 200°C. Alternatively, the solution can be concentrated to a syrup by distillation or freeze-drying.²⁴⁴ When the syrup is heated at low pressures, the cleavage reaction takes place at lower temperatures than are required for the reaction in the ordinary solution, probably because the base (HO^- or RO^-) is less solvated.²⁴⁵ The reaction has never been an important synthetic tool, but in the nineteenth century and the first part of the twentieth century, it saw much use in the determination of the structure of unknown amines, especially alkaloids. In many of these compounds, the nitrogen is in a ring, or even at a ring junction, and in such cases the alkene still contains nitrogen. Repetitions of the process are required to remove the nitrogen completely, as in the conversion of 2-methylpiperidine to 1,5-hexadiene by two rounds of exhaustive methylation followed by pyrolysis.

A side reaction involving nucleophilic substitution to give an alcohol ($\text{R}_4\text{N}^+ \text{OH}^- \rightarrow \text{ROH} + \text{R}_3\text{N}$) generally accompanies the normal elimination reaction,²⁴⁶ but seldom causes trouble. However, when none of the four groups on the nitrogen has a β hydrogen, substitution is the only reaction possible. On heating $\text{Me}_4\text{N}^+ \text{OH}^-$ in water, methanol is obtained, although without a solvent the product is not methanol, but dimethyl ether.²⁴⁷

The mechanism is usually E2. Hofmann's rule is generally obeyed by acyclic and Zaitsev's rule by cyclohexyl substrates (p. 1498). In certain cases, where the molecule is highly hindered, a five-membered Eⁱ mechanism, similar to that in **17-8**, has been shown to operate. That is, the hydroxide in these cases does not attract the β hydrogen, but instead removes one of the methyl hydrogens:

²⁴³For reviews, see Bentley, K.W., in Bentley, K.W.; Kirby, G.W. *Elucidation of Organic Structures by Physical and Chemical Methods*, 2nd ed. (Vol. 4 of Weissberger *Techniques of Chemistry*), pt. 2, Wiley, NY, **1973**, pp. 255–289; White, E.H.; Woodcock, D.J., in Patai, S. *The Chemistry of the Amino Group*, Wiley, NY, **1968**, pp. 409–416; Cope, A.C.; Trumbull, E.R. *Org. ²⁴⁶Baumgarten, R.J. *J. Chem. Educ.* **1968**, *45*, 122.

²⁴⁷Musker, W.K. *J. Chem. Educ.* **1968**, *45*, 200; Musker, W.K.; Stevens, R.R. *J. Am. Chem. Soc.* **1968**, *90*, 3515; Tanaka, J.; Dunning, J.E.; Carter, J.C. *J. Org. Chem.* **1966**, *31*, 3431.

The obvious way to distinguish between this mechanism and the ordinary E2 mechanism is by the use of deuterium labeling. For example, if the reaction is carried out on a quaternary hydroxide deuterated on the β carbon ($R_2CDCH_2NMe_3^+ ^-OH$), the fate of the deuterium indicates the mechanism. If the E2 mechanism is in operation, the trimethylamine produced would contain no deuterium (which would be found only in the water). But if the mechanism is Eⁱ, the amine would contain deuterium. In the case of the highly hindered compound $(Me_3C)_2CDCH_2NMe_3^+ ^-OH$, the deuterium did appear in the amine, demonstrating an E_i mechanism for this case.²⁴⁸ With simpler compounds, the mechanism is E2, since here the amine was deuterium-free.²⁴⁹

When the nitrogen bears more than one group possessing a β hydrogen, which group cleaves? The Hofmann rule says that *within* a group the hydrogen on the least alkylated carbon cleaves. This tendency is also carried over to the choice of which group cleaves: thus ethyl with three β hydrogens cleaves more readily than any longer *n*-alkyl group, all of which have two β hydrogens. "The β hydrogen is removed most readily if it is located on a methyl group, next from RCH_2 , and least readily from R_2CH ."²⁵⁰ In fact, the Hofmann rule as first stated²⁵¹ in 1851 applied only to which group cleaved, not to the orientation within a group; the latter could not have been specified in 1851, since the structural theory of organic compounds was not formulated until 1857–1860. Of course, the Hofmann rule (applied to which group cleaves *or* to orientation within a group) is superseded by conjugation possibilities. Thus $PhCH_2CH_2NMe_2Et^+ ^-OH$ gives mostly styrene instead of ethylene.

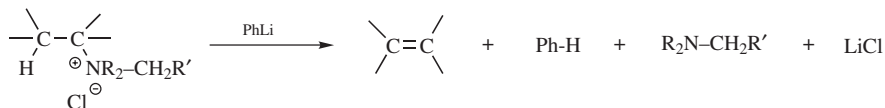

Triple bonds have been prepared by pyrolysis of 1,2-bis(ammonium) salts.²⁵²

When quaternary ammonium halides are treated with strong bases (e.g., PhLi, KNH₂ in liquid NH₃²⁵³), an elimination can occur that is similar in products, although not in mechanism, to **17-7**. This is an alternative to **17-7** and is done on the quaternary ammonium halide, so that it is not necessary to convert this to the hydroxide. The mechanism is Eⁱ:

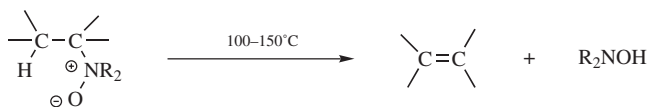

An α' hydrogen is obviously necessary in order for the ylid to be formed. This type of mechanism is called α',β elimination, since a β hydrogen is removed by the α' carbon. The mechanism has been confirmed by labeling experiments similar to those described at **17-7**,²⁵⁴ and by isolation of the intermediate ylids.²⁵⁵ An important synthetic difference between this and most instances of **17-7** is that syn-elimination is observed here and anti-elimination in **17-7**, so products of opposite configuration are formed when the alkene exhibits cis–trans isomerism.

An alternative procedure that avoids the use of a very strong base is heating the salt with KOH in polyethylene glycol monomethyl ether.²⁵⁶

Benzotriazole has been shown to be a good leaving group for elimination reactions. The reaction of an allylic benzotriazole (3-benzotriazolyl-4-trimethylsilyl-1-butene) with *n*-butyllithium, and then an alkyl halide leads to an alkylated 1,3-diene upon heating.²⁵⁷

17-9 Cleavage of Amine Oxides

Hydro-(Dialkyloxidoammonio)-elimination

Cleavage of amine oxides to produce an alkene and a hydroxylamine is called the *Cope reaction* or *Cope elimination* (not to be confused with the *Cope rearrangement*, **18-32**). It is an alternative to **17-7** and **17-8**.²⁵⁸ The reaction is usually

²⁵³Bach, R.D.; Bair, K.W.; Andrzejewski, D. *J. Am. Chem. Soc.* **1972**, *94*, 8608; *J. Chem. Soc., Chem. Commun.* **1974**, 819.

²⁵⁸For reviews, see Cope, A.C.; Trumbull, E.R. *Org. React.* **1960**, *11*, 317, see p. 361; DePuy, C.H.; King, R.W. *Chem. Rev.* **1960**, *60*, 431, see pp. 448–451.

performed with a mixture of amine and oxidizing agent (see **19-29**) without isolation of the amine oxide. Because of the mild conditions side reactions are few, and the alkenes do not usually rearrange. The reaction is thus very useful for the preparation of many alkenes. A limitation is that it does not open six-membered rings containing nitrogen, although it does open rings of 5 and 7–10 members.²⁵⁹ Rates of the reaction increase with increasing size of α and β -substituents.²⁶⁰ The reaction can be carried out at room temperature in dry Me_2SO or THF.²⁶¹ The elimination is a stereoselective syn process,²⁶² and the five-membered E^1 mechanism operates:

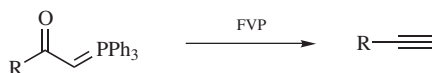

Almost all evidence indicates that the transition state must be planar. Deviations from planarity as in **17-4** (see p. 1507) are not found here, and indeed this is why six-membered heterocyclic nitrogen compounds do not react. Because of the stereoselectivity of this reaction and the lack of rearrangement of the products, it is useful for the formation of *trans*-cycloalkenes (eight-membered and higher). A polymer-bound Cope elimination reaction has been reported.²⁶³

OS IV, 612.

17-10 Pyrolysis of Keto-ylids

Hydro-(oxophosphoryl)-elimination

Phosphorus ylids are quite common (see **16-44**) and keto-phosphorus ylids [$\text{RCOCH}=\text{PPh}_3$] are also known. When these compounds are heated (flash vacuum pyrolysis, FVP) to $> 500^\circ\text{C}$, alkynes are formed. Simple alkynes²⁶⁴ can be formed as well as keto-alkynes²⁶⁵ and en-yne.²⁶⁶ Rearrangement from ylids derived from tertiary amines or α -diazo ketones is also known.²⁶⁷

17-11 Decomposition of Toluene-*p*-sulfonylhydrazones

Treatment of the tosylhydrazone of an aldehyde or a ketone with a strong base leads to the formation of an alkene, the reaction being formally an elimination accompanied by a hydrogen shift.²⁶⁸ The reaction (called the *Shapiro reaction*) has been applied to tosylhydrazones of many aldehydes and ketones. The most useful method synthetically involves treatment of the substrate with at least 2 equivalents of an organolithium compound²⁶⁹ (usually MeLi) in ether, hexane, or tetramethylenediamine.²⁷⁰ This procedure gives good yields of alkenes without side reactions and, where a choice is possible, predominantly gives the less highly substituted alkene. Tosylhydrazones of α,β -unsaturated ketones give conjugated dienes.²⁷¹ The mechanism²⁷² has been formulated as:

Evidence for this mechanism is (1) 2 equivalents of RLi are required; (2) the hydrogen in the product comes from the water and not from the adjacent carbon, as shown by deuterium labeling;²⁷³ and (3) the intermediates **32–34** have been trapped.²⁷⁴ This reaction, when performed in tetramethylenediamine, can be a synthetically useful method²⁷⁵ of generating vinylic lithium compounds (**34**), which

can be trapped by various electrophiles²⁷⁶ such as D₂O (to give deuterated alkenes), CO₂ (to give α,β-unsaturated carboxylic acids, **16-30**), or DMF (to give α,β-unsaturated aldehydes, **16-82**). Treatment of *N*-aziridino hydrazones with LDA leads to alkenes with high *cis* selectivity.²⁷⁷

The reaction also takes place with other bases (e.g., LiH,²⁷⁸ Na in ethylene glycol, NaH, NaNH₂) or with smaller amounts of RLi, but in these cases side reactions are common and the orientation of the double bond is in the other direction (to give the more highly substituted alkene). The reaction with Na in ethylene glycol is called the *Bamford–Stevens reaction*.²⁷⁹ For these reactions two mechanisms are possible: a carbenoid and a carbocation mechanism.²⁸⁰ The side reactions found are those expected of carbenes and carbocations. In general, the carbocation mechanism is chiefly found in protic solvents and the carbenoid mechanism in aprotic solvents. Both routes involve formation of a diazo compound (**35**) which in some cases can be isolated.

In fact, this reaction has been used as a synthetic method for the preparation of diazo compounds.²⁸¹ In the absence of protic solvents, **36** loses N₂, and hydrogen migrates, to give the alkene product. The migration of

²⁸¹For a review, see Regitz, M.; Maas, G. *Diazo Compounds*; Academic Press, NY, **1986**, pp. 257–295. For an improved procedure, see Wulfman, D.S.; Yousefian, S.; White, J.M. *Synth. Commun.* **1988**, 18, 2349.

hydrogen may immediately follow, or be simultaneous with, the loss of N₂. In a protic solvent, **35** becomes protonated to give the diazonium ion **36**, which loses N₂ to give the corresponding carbocation, that may then undergo elimination or give other reactions characteristic of carbocations. A diazo compound is an intermediate in the formation of alkenes by treatment of *N*-nitrosoamides with a rhodium(II) catalyst.²⁸²

17-12 Cleavage of Sulfoxides, Selenoxides, and Sulfones

Sulfonium compounds ($-\text{C}^+\text{SR}_2$) undergo elimination similar to that of their ammonium counterparts (**17-7** and **17-8**) in scope and mechanism but this reaction is not of great synthetic importance. These syn-elimination reactions are related to the Cope elimination (**17-9**) and the Hofmann elimination (**17-7**).²⁸³

Sulfoxides and sulfones²⁸⁴ with a β hydrogen, on the other hand, undergo elimination on treatment with an alkoxide or, for sulfones,²⁸⁵ even with hydroxide.²⁸⁶ Sulfones also eliminate in the presence of an organolithium reagent and a palladium catalyst.²⁸⁷ Mechanistically, these reactions belong on the E1-E2-E1cB spectrum.²⁸⁸ Although the leaving groups are uncharged, the orientation follows Hofmann's rule, not Zaitsev's. Sulfoxides (but not sulfones) also undergo elimination

on pyrolysis at $\sim 80^\circ\text{C}$ in a manner analogous to **17-9**. The mechanism is also analogous, being the five-membered E^i mechanism with syn elimination.²⁸⁹

Selenoxides²⁹⁰ and sulfinates $\text{R}_2\text{CH}-\text{CHR}-\text{SO}-\text{OMe}$ ²⁹¹ also undergo elimination by the E^i mechanism, the selenoxide reaction taking place at room temperature. The reaction with selenoxides has been extended to the formation of triple bonds.²⁹²

Both the selenoxide²⁹³ and sulfoxide²⁹⁴ reactions have been used in a method for the conversion of ketones, aldehydes, and carboxylic esters to their α,β -unsaturated derivatives (illustrated for the selenoxide).

Because of the mildness of the procedure, this is probably the best means of accomplishing this conversion. Treatment of ketones with LDA and then $\text{PhCIS}=\text{N}t\text{-Bu}$ leads to the conjugated ketone.²⁹⁵ Allylic sulfoxides undergo 1,4-elimination to give dienes.²⁹⁶ Ketones also react with hypervalent iodine compound in DMSO to give conjugated ketone.²⁹⁷ In a similar manner, ketones are converted to conjugated ketones by heating with $\text{HIO}_5/\text{I}_2\text{O}_5$ in DMSO.²⁹⁸

17-13 Dehydrohalogenation of Alkyl Halides

Hydro-halo-elimination

The elimination of HX from an alkyl halide is a very general reaction and can be accomplished with chlorides, fluorides, bromides, and iodides.³⁰⁰ Hot alcoholic KOH is the most frequently used base, although stronger bases³⁰¹ (OR^- , NH_2^- , etc.) or weaker ones (e.g., amines) are used where warranted.³⁰² The bicyclic amidines 1,5-diazabicyclo[3.4.0]nonene-5 (DBN)³⁰³ and 1,8-diazabicyclo[5.4.0]undecene-7 (DBU)³⁰⁴ are good reagents for difficult cases.³⁰⁵ Dehydrohalogenation with the non-ionic base $(\text{Me}_2\text{N})_3\text{P}=\text{N}-\text{P}(\text{NMe}_2)_2=\text{NMe}$ is even faster.³⁰⁶ Phase-transfer catalysis has been used with hydroxide as base.³⁰⁷ As previously mentioned (p. 1495), certain weak bases in dipolar aprotic solvents are effective reagents for dehydrohalogenation. Among those most often used for synthetic purposes are LiCl or LiBr–LiCO₃ in DMF.³⁰⁸ Dehydrohalogenation has also been effected by heating of the alkyl halide in HMPA with no other reagent present.³⁰⁹ As in

nucleophilic substitution (p. 496), the order of leaving group reactivity is $I > Br > Cl > F$.³¹⁰

Tertiary halides undergo elimination most easily. Eliminations of chlorides, bromides, and iodides follow Zaitsev's rule, except for a few cases where steric effects are important (for an example, see p. 1499). Eliminations of fluorides follow Hofmann's rule (p. 1500).

This reaction is by far the most important way of introducing a triple bond into a molecule.³¹¹ Alkyne formation can be accomplished with substrates of the types:³¹²

When the base is NaNH_2 1-alkynes predominate (where possible), because this base is strong enough to form the salt of the alkyne, shifting any equilibrium between 1- and 2-alkynes. When the base is OH^- or OR^- , the equilibrium tends to be shifted to the internal alkyne, which is thermodynamically more stable. If another hydrogen is suitably located (e.g., $-\text{CRH}-\text{CX}_2-\text{CH}_2-$), allene formation can compete, although alkynes are usually more stable.³¹³ 1,1,2-Trihalocyclopropanes are converted to alkynes by ring opening reactions.³¹³

Dehydrohalogenation is generally carried out in solution, with a base, and the mechanism is usually E2, although the E1 mechanism has been demonstrated in some cases. However, elimination of HX can be accomplished by pyrolysis of the halide, in which case the mechanism is Eⁱ (p. 1507) or, in some instances, the free-radical mechanism (p. 1510). Pyrolysis is normally performed without a catalyst at $\sim 400^\circ\text{C}$. The pyrolysis reaction is not generally useful synthetically, because of its reversibility. Less work has been done on pyrolysis with a catalyst³¹⁴ (usually a metallic oxide or salt), but the mechanisms here are probably E1 or E2.

17-14 Dehydrohalogenation of Acyl Halides and Sulfonyl Halides

Hydro-halo-elimination

Ketenes can be prepared by treatment of acyl halides with tertiary amines³¹⁷ or with NaH and a crown ether.³¹⁸ The scope is broad, and most acyl halides possessing an α hydrogen give the reaction, but if at least one R is hydrogen, only the ketene dimer, not the ketene, is isolated. However, if it is desired to use a reactive ketene in a reaction with a given compound, the ketene can be generated *in situ* in the presence of the given compound.³¹⁹

Closely related is the reaction of tertiary amines with sulfonyl halides that contain an α hydrogen. In this case, the initial product is the highly reactive sulfene, which cannot be isolated but reacts further to give products, one of which may be the alkene that is the dimer of RCH.³²⁰ Reactions of sulfenes *in situ* are also common (e.g., see **16-48**).

17-15 Elimination of Boranes

Hydro-borane-triyl-elimination

Trialkylboranes are formed from an alkene and BH_3 (**15-16**). When the resulting borane is treated with another alkene, an exchange reaction occurs.³²¹ This is an equilibrium process that can be shifted by using a large excess of alkene, by using an unusually reactive alkene, or by using an alkene with a higher boiling point than the displaced alkene and removing the latter by distillation. The reaction is useful for shifting a double bond in the direction opposite to that resulting from normal isomerization methods (**12-2**). This cannot be accomplished simply by treatment of a borane, such as **39**, with an alkene, because elimination in this reaction follows Zaitsev's rule: It is in the direction of the most stable alkene, and the product would be **38**, not **41**. However, if it is desired to convert **38** to **41**, this can be accomplished by converting **38** to **39**, isomerizing **39** to **40** (**18-11**) and then subjecting **40** to the exchange reaction with a higher boiling alkene (e.g., 1-decene), whereupon **41** is produced. In the usual isomerizations (**12-2**), **41** could be isomerized to **38**, but not the other way around. The reactions $\text{39} \rightarrow \text{40}$ and $\text{40} \rightarrow \text{41}$ proceed essentially without rearrangement. The mechanism is probably the reverse of borane addition (**15-16**).

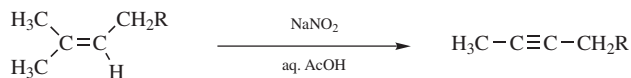

A similar reaction, but irreversible, has been demonstrated for alkynes.³²²

17-16 Conversion of Alkenes to Alkynes

Hydro-methyl-elimination

Alkenes of the form shown lose the elements of methane when treated with sodium nitrite in acetic acid and water, to form alkynes in moderate-to-high yields.³²³ The R may contain additional unsaturation, as well as OH, OR, OAc,

³²¹Brown, H.C.; Bhatt, M.V.; Munkata, T.; Zweifel, G. *J. Am. Chem. Soc.* **1967**, *89*, 567; Taniguchi, H. *Bull. Chem. Soc. Jpn.* **1979**, *52*, 2942.

C=O, and other groups, but the $\text{Me}_2\text{C}=\text{CHCH}_2$ portion of the substrate is necessary for the reaction to take place. The mechanism is complex, beginning with a nitration that takes place with allylic rearrangement [$\text{Me}_2\text{C}=\text{CHCH}_2\text{R} \rightarrow \text{H}_2\text{C}=\text{C}(\text{Me})\text{CH}(\text{NO}_2)\text{CH}_2\text{R}$], and involving several additional intermediates.³²⁴ The CH_3 lost from the substrate appears as CO_2 , as demonstrated by the trapping of this gas.³²⁴

1,1-Dibromoalkenes are converted to alkynes when treated with *n*-butyllithium.³²⁵ This transformation is a modification of the *Fritsch–Buttenberg–Wiechell rearrangement*.³²⁶ Vinyl sulfoxides that contain a leaving group, such as chloride on the double bond, react with *tert*-butyllithium to give a lithio alkyne, and hydrolysis leads to the final product, an alkyne.

17-17 Decarbonylation of Acyl Halides

Hydro-chloroformyl-elimination

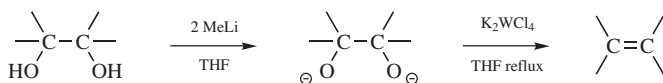

Acyl chlorides containing an α -hydrogen are smoothly converted to alkenes, with loss of HCl and CO, on heating with chlorotris(triphenylphosphine)rhodium, with metallic platinum, or with certain other catalysts.³²⁷ The mechanism probably involves conversion of $\text{RCH}_2\text{CH}_2\text{COCl}$ to $\text{RCH}_2\text{CH}_2\text{-RhCO}(\text{Ph}_3\text{P})_2\text{Cl}_2$ followed by a concerted syn elimination of Rh and H³²⁸ (see also, 14-32 and 19-12).

B. Reactions in Which Neither Leaving Atom Is Hydrogen

17-18 Deoxygenation of Vicinal Diols

Dihydroxy-elimination

vic-Diols can be deoxygenated by treatment of the dilithium dialkoxide with the tungsten halide (K_2WCl_6), or with certain other tungsten reagents, in refluxing THF.³²⁹ Tetrasubstituted diols react most rapidly. The elimination is largely, but

not entirely, *syn*. Several other methods have been reported,³³⁰ in which the diol is deoxygenated directly, without conversion to the dialkoxide. These include treatment with titanium metal,³³¹ with TsOH–NaI,³³² and by heating with CpReO₃, where Cp is cyclopentadienyl.³³³

vic-Diols can also be deoxygenated indirectly, through sulfonate ester derivatives. For example, *vic*-dimesylates and *vic*-ditosylates have been converted to alkenes by treatment, respectively, with naphthalene-sodium³³⁴ and with NaI in DMF.³³⁵ In another procedure, the diols are converted to bisdithiocarbonates (bis xanthates), which undergo elimination (probably by a free-radical mechanism) when

treated with tri-*n*-butylstannane in toluene or benzene.³³⁶ *vic*-Diols can also be deoxygenated through cyclic derivatives (**17-19**).

17-19 Cleavage of Cyclic Thionocarbonates

Cyclic thionocarbonates (**42**) can be cleaved to alkenes (the *Corey–Winter reaction*)³³⁷ by heating with trimethyl phosphite³³⁸ or other trivalent phosphorus compounds³³⁹ or by treatment with bis(1,5-cyclooctadiene)nickel.³⁴⁰ The

thionocarbonates can be prepared by treatment of 1,2-diols with thiophosgene and 4-dimethylaminopyridine (DMAP):³⁴¹

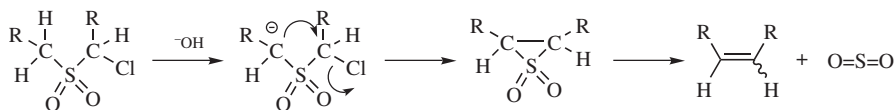

The elimination is of course syn, so the product is sterically controlled. Alkenes that are not sterically favored can be made this way in high yield, (e.g., *cis*-PhCH₂CH=CHCH₂Ph).³⁴² Certain other five-membered cyclic derivatives of 1,2-diols can also be converted to alkenes.³⁴³

17-20 The Ramberg–Bäcklund Reaction

Ramberg–Bäcklund halosulfone transformation

The reaction of an α -halo sulfone with a base to give an alkene is called the *Ramberg–Bäcklund reaction*.³⁴⁴ The reaction is quite general for α -halo sulfones with an α' hydrogen, despite the unreactive nature of α -halo sulfones in normal S_N2 reactions (p. 486). Halogen reactivity is in the order I > Br \gg Cl. Phase-transfer catalysis has been used.³⁴⁵ In general, mixtures of *cis* and *trans* isomers are obtained, but usually the less stable *cis* isomer predominates. The mechanism involves formation of an episulfone, and then elimination of SO₂. There is much

³⁴⁵ Hartman, G.D.; Hartman, R.D. *Synthesis* **1982**, 504.

evidence for this mechanism,³⁴⁶ including the isolation of the episulfone intermediate,³⁴⁷ and the preparation of episulfones in other ways and the demonstration that they give alkenes under the reaction conditions faster than the corresponding α -halo sulfones.³⁴⁸ Episulfones synthesized in other ways (e.g., **16-48**) are reasonably stable compounds, but eliminate SO_2 to give alkenes when heated or treated with base.

If the reaction is run on the unsaturated bromo sulfones $\text{RCH}_2\text{CH}=\text{CHSO}_2\text{CH}_2\text{Br}$ (prepared by reaction of $\text{BrCH}_2\text{SO}_2\text{Br}$ with $\text{RCH}_2\text{CH}=\text{CH}_2$ followed by treatment with Et_3N), the dienes $\text{RCH}=\text{CHCH}=\text{CH}_2$ are produced in moderate-to-good yields.³⁴⁹ The compound mesyltriflone $\text{CF}_3\text{SO}_2\text{CH}_2\text{SO}_2\text{CH}_3$ can be used as a synthon for the tetraion $^{2-}\text{C}=\text{C}^{2-}$. Successive alkylation (**10-67**) converts it to $\text{CF}_3\text{SO}_2\text{CR}^1\text{R}^2\text{SO}_2\text{CHR}^3\text{R}^4$ (anywhere from one to four alkyl groups can be put in), which, when treated with base, gives $\text{R}^1\text{R}^2\text{C}=\text{CR}^3\text{R}^4$.³⁵⁰ The nucleofuge here is the CF_3SO_2^- ion.

2,5-Dihydrothiophene-1,1-dioxides (**43**) and 2,17-dihydrothiepin-1,1-dioxides (**44**) undergo analogous 1,4- and 1,6-eliminations, respectively (see also, **17-36**). These are concerted reactions and, as predicted by the orbital-symmetry rules (p. 1207), the former³⁵¹ is a suprafacial process and the latter³⁵² an antarafacial process. The rules also predict that elimination of SO_2 from episulfones cannot take place by a concerted mechanism (except antarafacially, which is unlikely for such a small ring), and the evidence shows that this reaction occurs by a nonconcerted pathway.³⁵³ The eliminations of SO_2 from **43** and **44** are examples of *cheletropic reactions*,³⁵⁴ which are defined as reactions in which two σ bonds that terminate

at a single atom (in this case the sulfur atom) are made or broken in concert.³⁵⁵

α,α -Dichlorobenzyl sulfones (**45**) react with an excess of the base triethylenediamine (TED) in DMSO at room temperature to give 2,3-diarylthiiren-1,1-dioxides (**46**), which can be isolated.³⁵⁶ Thermal decomposition of **46** gives the alkynes **47**.³⁵⁷

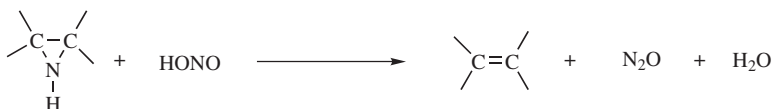

A Ramberg–Bäcklund-type reaction has been carried out on the α -halo sulfides (ArCHClSCH₂Ar), which react with *t*-BuOK and PPh₃ in refluxing THF to give the alkenes (ArCH=CHAr).³⁵⁸ Cyclic sulfides lead to ring-contracted cyclic alkenes upon treatment with NCS in CCl₄ followed by oxidation with *m*-chloroperoxybenzoic acid.³⁵⁹

The Ramberg–Bäcklund reaction can be regarded as a type of extrusion reaction (see p. 1553).

OS V, 877; VI, 454, 555; VIII, 212.

17-21 The Conversion of Aziridines to Alkenes

epi-Imino-elimination

Aziridines not substituted on the nitrogen atom react with nitrous acid to produce alkenes.³⁶⁰ An *N*-nitroso compound is an intermediate (**12-50**); other reagents that produce such intermediates also give alkenes. The reaction is stereospecific: cis aziridines give cis alkenes and trans aziridines give trans alkenes.³⁶¹ Aziridines carrying *N*-alkyl substituents can be converted to alkenes by treatment with ferrous iodide³⁶² or with *m*-chloroperoxybenzoic acid.³⁶³ An *N*-oxide intermediate

(19-29) is presumably involved in the latter case. *N*-Tosyl aziridines are converted to *N*-tosyl imines when treated with boron trifluoride.³⁶⁴ 2-Tosylmethyl *N*-tosylaziridines react with Te²⁻ in the presence of Adogen 464 to give allylic *N*-tosyl amines.³⁶⁵ 2-Halomethyl *N*-tosyl aziridines also react with indium metal in methanol to give *N*-tosyl allylic amines.³⁶⁶

17-22 Elimination of Vicinal Dihalides

Dihalo-elimination

Dehalogenation has been accomplished with many reagents, the most common being zinc, magnesium, and iodide ion.³⁶⁷ Heating in HMPA is often enough to convert a *vic*-dibromide to an alkene.³⁶⁸ Among reagents used less frequently have been phenyllithium, phenylhydrazine, CrCl₂, Na₂S in DMF,³⁶⁹ and LiAlH₄.³⁷⁰ Electrochemical reduction has also been used.³⁷¹ Treatment with In³⁷² or Sm³⁷³ metal in CH₃OH, InCl₃/NaBH₄,³⁷⁴ a Grignard reagent and Ni(dppe)Cl₂, (dppe = 1, 2-diphenylphosphinoethane),³⁷⁵ nickel compounds with Bu₃SnH,³⁷⁶ or SmI₂³⁷⁷ leads to the alkene. Although the reaction usually gives good yields, it is not very useful because the best way to prepare *vic*-dihalides is by the addition of halogen to a double bond (15-39). One useful feature of this reaction is that there is no doubt about the *position* of the new double bond, so that it can be used to give double bonds exactly where they are wanted. For example, allenes, which are not easily prepared by other methods, can be prepared from X-C-CX₂-C-X or X-C-CX=C- systems.³⁷⁸ Cumulenes

have been obtained from 1,4-elimination:

Cumulenes have also been prepared by treating alkynyl epoxides with boron trifluoride.³⁷⁹ 1,4-Elimination of BrC-C=C-CBr has been used to prepare conjugated dienes C=C-C=C .³⁸⁰ Allenes are formed by heating propargylic alcohols with arylboronic acids (p. 815) and a palladium catalyst.³⁸¹ Allenes are also formed from propargylic amines using a CuI and a palladium catalyst.³⁸²

The reaction of a vicinal dibromide with triethylamine and DMF with microwave irradiation leads to vinyl bromide.³⁸³ Alkenes are formed from vicinal bromides by heating with iron in methanol³⁸⁴ or samarium in the presence of TMSCl and a trace of water.³⁸⁵ α,β -Dibromo amides are converted to conjugated amides upon photolysis in methanol.³⁸⁶

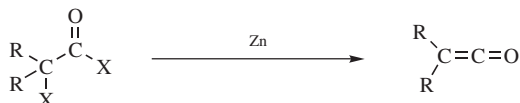

The reaction can be carried out for any combination of halogens, except where one is fluorine. Mechanisms are often complex and depend on the reagent and reaction conditions.³⁸⁷ For different reagents, mechanisms involving carbocations, carbanions, and free-radical intermediates, as well as concerted mechanisms, have been proposed. When the reagent is zinc, anti stereospecificity has been observed in some cases,³⁸⁸ but not in others.³⁸⁹

Note that geminal dibromo cyclopropanes (1,1-dibromocyclopropanes) are opened to conjugated dienes by heating to 500°C .³⁹⁰

Ketenes can be prepared by dehalogenation of α -halo acyl halides with zinc or with triphenylphosphine.³⁹¹ The reaction generally gives good results when the two R groups are aryl or alkyl, but not when either one is hydrogen.³⁹²

OS IV, 348; VIII, 377.

17-24 Elimination of a Halogen and a Hetero Group

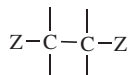

Alkoxy-halo-elimination

The elimination of OR and halogen from β -halo ethers is called the *Boord reaction*. It can be carried out with zinc, magnesium, sodium, or certain other reagents.³⁹³ The yields are high and the reaction is of broad scope. β -Halo acetals readily yield vinylic ethers

and 2 equivalents of SmI_2 in HMPA is effective.³⁹⁴ Besides β -halo ethers, the reaction can also be carried out on compounds of the formula

where X is halogen and Z is OCOR, OTs,³⁹⁵ NR_2 ,³⁹⁶ or SR.³⁹⁷ When X = Cl and Z = OAc, heating in THF with an excess of SmI_2 followed by treatment with dilute aq. HCl gives an alkene.³⁹⁸ When Z = I and the other Z is an oxygen of an oxazolonone (a carbamate unit), heating with indium metal in methanol leads to an allylic amine.³⁹⁹ The Z group may also be OH, but then X is limited to Br and I.⁴⁰⁰ Like **17-22**, this method ensures that the new double bond will be in a specific position.

The fact that magnesium causes elimination in these cases limits the preparation of Grignard reagents from these compounds. It has been shown that treatment of β -halo ethers and esters with zinc gives nonstereospecific elimination,⁴⁰¹ so the mechanism was not E2. An E1cB mechanism was postulated because of the poor leaving-group ability of OR and OCOR. Bromohydrins can be converted to alkenes (elimination of Br, OH) in high yields by treatment with $\text{LiAlH}_4\text{-TiCl}_3$.⁴⁰²

OS III, 698, IV, 748; VI, 675.

FRAGMENTATIONS

When carbon is the positive leaving group (the electrofuge) in an elimination, the reaction is called *fragmentation*.⁴⁰³ These processes occur on substrates of the form W-C-C-X , where X is a normal nucleofuge (e.g., halogen, OH_2^+ , OTs, NR_3^+) and W is a positive-carbon electrofuge. In most of the cases, W is HO-C- or $\text{R}_2\text{N-C-}$, so that the positive charge on the carbon atom is stabilized by the unshared pair of the oxygen or nitrogen, for example,

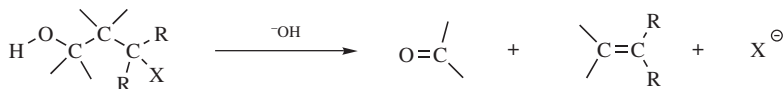

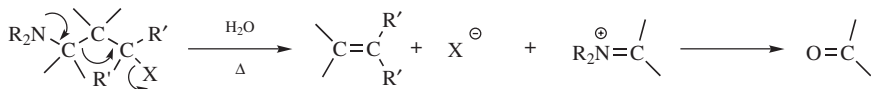

The mechanisms are mostly E1 or E2. We will discuss only a few fragmentations, since many are possible and not much work has been done on most of them. Reactions 17-25–17-28 and 17-30 may be considered fragmentations (see also 19-12 and 19-13).

⁴⁰³For reviews, see Becker, K.B.; Grob, C.A., in Patai, S. *The Chemistry of Functional Groups, Supplement A*, pt. 2, Wiley, NY, **1977**, pp. 653–723; Grob, C.A. *Angew. Chem. Int. Ed.* **1969**, 8, 535; Grob, C.A.; Schiess, P.W. *Angew. Chem. Int. Ed.* **1967**, 6, 1.

γ -Dialkylamino halides undergo fragmentation when heated with water to give an alkene and an iminium salt, which under the reaction conditions is hydrolyzed to an aldehyde or ketone (**16-2**).⁴⁰⁴ γ -Hydroxy halides and tosylates are fragmented with base. In this instance, the base does not play its usual role in elimination reactions, but instead serves to remove a proton from the OH group, which enables the carbon leaving group to come off more easily:

The mechanism of these reactions is often E1. However, in at least some cases, an E2 mechanism operates.⁴⁰⁵ It has been shown that stereoisomers of cyclic γ -amino halides and tosylates in which the two leaving groups can assume an antiperiplanar conformation react by the E2 mechanism, while those isomers in which the groups cannot assume such a conformation either fragment by the E1 mechanism or do not undergo fragmentation at all, but in either case give rise to side products characteristic of carbocations.⁴⁰⁶

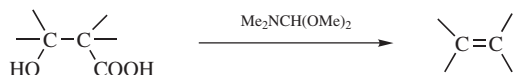

γ -Dialkylamino alcohols do not give fragmentation, since for ionization the OH group must be converted to OH_2^+ and this would convert NR_2 to NR_2H^+ , which does not have the unshared pair necessary to form the double bond with the carbon.⁴⁰⁷

1,3-Diols in which at least one OH group is tertiary or is located on a carbon with aryl substituents can be cleaved by acid treatment.⁴⁰⁸ The reaction is most useful synthetically when at least one of the OH groups is on a ring.⁴⁰⁹

17-26 Decarboxylation of β -Hydroxy Carboxylic Acids and of β -Lactones

Carboxy-hydroxy-elimination

An OH and a COOH group can be eliminated from β -hydroxy carboxylic acids by refluxing with excess dimethylformamide dimethyl acetal.⁴¹⁰ Mono-, di-, tri-, and tetrasubstituted alkenes have been prepared by this method in good yields.⁴¹¹

⁴¹¹For a 1,4 example of this reaction, see Rüttimann, A.; Wick, A.; Eschenmoser, A. *Helv. Chim. Acta* **1975**, *58*, 1450.

There is evidence that the mechanism involves E1 or E2 elimination from the zwitterionic intermediate⁴¹²

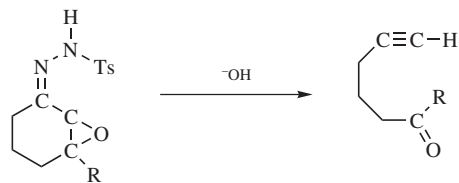

The reaction has also been accomplished⁴¹³ under extremely mild conditions (a few seconds at 0°C) with PPh₃ and diethyl azodicarboxylate EtOOC-N=N-COOEt.⁴¹⁴ In a related procedure, β-lactones undergo thermal decarboxylation to give alkenes in high yields. The reaction has been shown to be a stereospecific syn-elimination.⁴¹⁵ There is evidence that this reaction also involves a zwitterionic intermediate.⁴¹⁶

There are no OS references, but see OS VII, 172, for a related reaction.

17-27 Fragmentation of α,β-Epoxy Hydrazones

Eschenmoser–Tanabe ring cleavage

Cyclic α,β-unsaturated ketones⁴¹⁷ can be cleaved by treatment with base of their epoxy tosylhydrazone derivatives to give acetylenic ketones.⁴¹⁸ The reaction can be applied to the formation of acetylenic aldehydes (R = H) by using the

corresponding, 2,4-dinitro-tosylhydrazone derivatives.⁴¹⁹ Hydrazones (e.g., **48**) prepared from epoxy ketones and ring-substituted *N*-aminoaziridines undergo similar fragmentation when heated.⁴²⁰

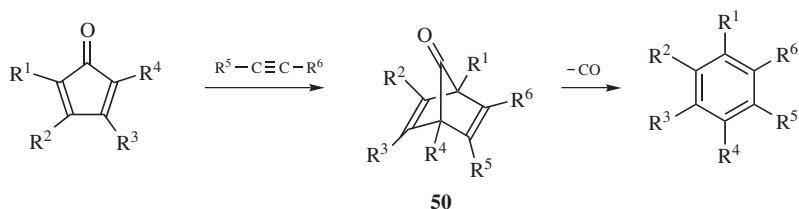

OS VI, 679.

17-28 Elimination of CO and CO₂ from Bridged Bicyclic Compounds

seco-Carbonyl-1/4/elimination

On heating, bicyclo[2.2.1]hept-2,3-en-17-ones (**49**) usually lose CO to give cyclohexadienes,⁴²¹ in a type of reverse Diels–Alder reaction. Bicyclo[2.2.1]heptadienones (**50**) undergo the reaction so readily (because of the

stability of the benzene ring produced) that they cannot generally be isolated. The parent **50** has been obtained at 10–15°K in an Ar matrix, where its spectrum could be studied.⁴²² Both **49** and **50** can be prepared by Diels–Alder reactions between a cyclopentadienone and an alkyne or alkene, so that this reaction is a useful method for the preparation of specifically substituted benzene rings and cyclohexadienes.⁴²³

is effective for this transformation.⁴³⁷ Microwave irradiation on EPZ-10⁴³⁸ or sulfuric acid impregnated silica gel⁴³⁹ gives the nitrile, as does microwave irradiation of an oxime with tetrachloropyridine on alumina.⁴⁴⁰ Aldehydes can be converted to oximes *in situ* and microwave irradiation on alumina⁴⁴¹ or with ammonium acetate⁴⁴² gives the nitrile. Solvent-free reactions are known.⁴⁴³ Electrochemical synthesis has also been used.⁴³⁵ The reaction is most successful when the H and OH are anti. Various alkyl and acyl derivatives of aldoximes, for example, RCH=NOR, RCH=NOCOR, RCH=NOSO₂Ar, and so on, also give nitriles, as do chlorimines RCH=NCl (the latter with base treatment).⁴⁴⁴ *N,N*-Dichloro derivatives of primary amines give nitriles on pyrolysis: RCH₂NCl₂ → RCN.⁴⁴⁵

Quaternary hydrazoneium salts (derived from aldehydes) give nitriles when treated with ⁻OEt⁴⁴⁶ or DBU (p. 1132).⁴⁴⁷ as do dimethylhydrazones, RCH=NNMe₂, when treated with Et₂NLi and HMPA.⁴⁴⁸ All these are methods of converting aldehyde derivatives to nitriles. For the conversion of aldehydes directly to nitriles, without isolation of intermediates (see **16-16**).

Hydroxylamines that have an α-proton are converted to nitriles when treated with a manganese salen complex.⁴⁴⁹

Certain ketoximes can be converted to nitriles by the action of proton or Lewis acids.⁴⁵⁰ Among these are oximes of α-diketones (illustrated above), α-keto acids,

α -dialkylamino ketones, α -hydroxy ketones, β -keto ethers, and similar compounds.⁴⁵¹ These are fragmentation reactions, analogous to **17-25**. For example, α -dialkylamino ketoximes also give amines and aldehydes or ketones besides nitriles:⁴⁵²

The reaction that normally occurs on treatment of a ketoxime with a Lewis or proton acid is the Beckmann rearrangement (**18-17**); fragmentations are considered side reactions, often called “abnormal” or “second-order” Beckmann rearrangements.⁴⁵³ Obviously, the substrates mentioned are much more susceptible to fragmentation than are ordinary ketoximes, since in each case an unshared pair is available to assist in removal of the group cleaving from the carbon. However, fragmentation is a side reaction even with ordinary ketoximes⁴⁵⁴ and, in cases where a particularly stable carbocation can be cleaved, may be the main reaction:⁴⁵⁵

There are indications that the mechanism at least in some cases first involves a rearrangement and then cleavage. The ratio of fragmentation to Beckmann rearrangement of a series of oxime tosylates, $\text{RC}(=\text{NOTs})\text{Me}$, was not related to the solvolysis rate but *was* related to the stability of R^+ (as determined by the solvolysis rate of the corresponding RCl), which showed that fragmentation did not take place in the rate-determining step.⁴⁵⁶ It may be postulated then that the first step in the fragmentation and in the rearrangement is the same and that this is the rate-determining step. The product is determined in the second step:

REACTIONS IN WHICH C=O BONDS ARE FORMED

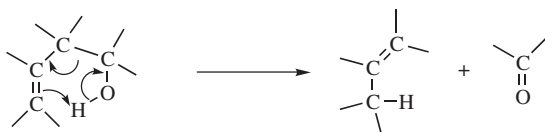

Many elimination reactions in which C=O bonds are formed were considered in Chapter 16, along with their more important reverse reactions (also see, 12-40 and 12-41).

17-32 Pyrolysis of β -Hydroxy Alkenes

O-Hydro-C-allyl-elimination

When pyrolyzed, β -hydroxy alkenes cleave to give alkenes and aldehydes or ketones.⁴⁹¹ Alkenes produced this way are quite pure, since there are no side reactions. The mechanism has been shown to be pericyclic, primarily by observations that the kinetics are first order⁴⁹² and that, for ROD, the deuterium appeared in the allylic position of the new alkene.⁴⁹³ This mechanism is the reverse of that for the oxygen analog of the ene synthesis (16-54). β -Hydroxyacetylenes react similarly to give the corresponding allenes and carbonyl compounds.⁴⁹⁴ The mechanism is the same despite the linear geometry of the triple bonds.

In a related reaction, pyrolysis of allylic ethers that contain at least one α hydrogen gives alkenes and aldehydes or ketones. The mechanism is also pericyclic⁴⁹⁵

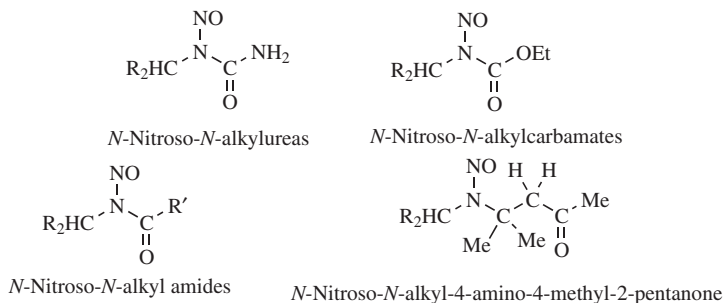

REACTIONS IN WHICH N=N BONDS ARE FORMED

17-33 Eliminations to Give Diazoalkanes

N-Nitrosoamine-diazoalkane transformation

Various *N*-nitroso-*N*-alkyl compounds undergo elimination to give diazoalkanes.⁴⁹⁶ One of the most convenient methods for the preparation of diazomethane involves base treatment of *N*-nitroso-*N*-methyl-*p*-toluenesulfonamide (illustrated above, with R = H).⁴⁹⁷ However, other compounds commonly used are (base treatment is required in all cases):

All these compounds can be used to prepare diazomethane, although the sulfonamide, which is commercially available, is most satisfactory. *N*-Nitroso-*N*-methylcarbamate and *N*-nitroso-*N*-methylurea give good yields, but are highly irritating and carcinogenic.⁴⁹⁸ For higher diazoalkanes the preferred substrates are nitrosoalkylcarbamates.

EXTRUSION REACTIONS

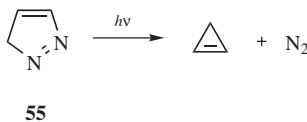

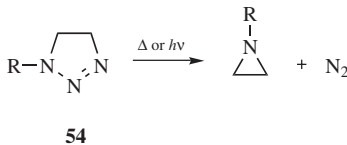

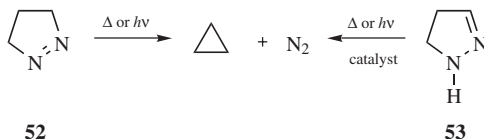

We consider an *extrusion reaction*⁴⁹⁹ to be one in which an atom or group Y connected to two other atoms X and Z is lost from a molecule, leading to a product in which X is bonded directly to Z.

Reactions 14-32 and 17-20 also fit this definition. Reaction 17-28 does not fit the definition, but is often also classified as an extrusion reaction. An extrusibility scale has been developed, showing that the ease of extrusion of the common Y groups is in the order: $-\text{N}=\text{N}- > -\text{COO}- > -\text{SO}_2- > -\text{CO}-$.⁵⁰⁰

17-34 Extrusion of N₂ from Pyrazolines, Pyrazoles, and Triazolines

Azo-extrusion

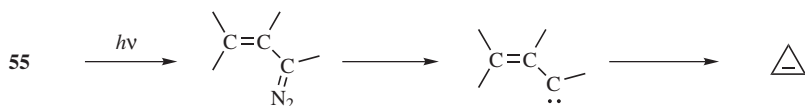

⁴⁹⁹For a monograph, see Stark, B.P.; Duke, A.J. *Extrusion Reactions*, Pergamon, Elmsford, NY, 1967. For a review of extrusions that are photochemically induced, see Givens, R.S. *Org. Photochem.* **1981**, 5, 227.

⁵⁰⁰Paine, A.J.; Warkentin, J. *Can. J. Chem.* **1981**, 59, 491.

1-Pyrazolines (**52**) can be converted to cyclopropane and N_2 on photolysis⁵⁰¹ or pyrolysis.⁵⁰² The tautomeric 2-pyrazolines (**53**), which are more stable than **52** also give the reaction, but in this case an acidic or basic catalyst is required, the function of which is to convert **53** to **52**.⁵⁰³ In the absence of such catalysts, **53** do not react.⁵⁰⁴ In a similar manner, triazolines (**54**) are converted to aziridines.⁵⁰⁵ Side reactions are frequent with both **52** and **54**, and some substrates do not give the reaction at all. However, the reaction has proved synthetically useful in many cases. In general, photolysis gives better yields and fewer side reactions than pyrolysis with both **52** and **54**. 3*H*-Pyrazoles⁵⁰⁶ (**55**) are stable to heat, but in some cases can be converted to cyclopropenes on photolysis,⁵⁰⁷ although in other cases other types of products are obtained.

There is much evidence that the mechanism⁵⁰⁸ of the 1-pyrazoline reactions generally involves diradicals, although the mode of formation and detailed structure (e.g., singlet vs. triplet) of these radicals may vary with the substrate and reaction conditions. The reactions of the 3*H*-pyrazoles have been postulated to proceed through a diazo compound that loses N_2 to give a vinylic carbene.⁵⁰⁹

17-35 Extrusion of CO or CO₂

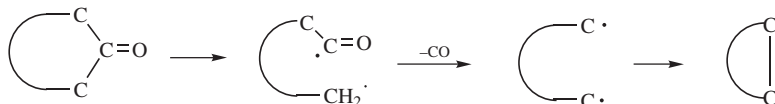

Carbonyl-extrusion

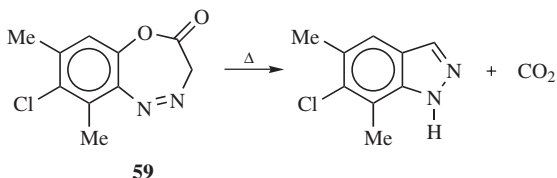

Although the reaction is not general, certain cyclic ketones can be photolyzed to give ring-contracted products.⁵¹⁰ In the example above, the cyclobutanone **56** was photolyzed to give **57**.⁵¹¹ This reaction was used to synthesize tetra-*tert*-butyltetrahydra-**58**.⁵¹²

The mechanism probably involves a Norrish type I cleavage (p. 343), loss of CO from the resulting radical, and recombination of the radical fragments.

Certain lactones extrude CO₂ on heating or on irradiation, such as the pyrolysis of **59**.⁵¹³

⁵¹⁰For reviews of the reactions in this section, see Redmore, D.; Gutsche, C.D. *Adv. Alicyclic Chem.* **1971**, *3*, 1, see pp. 91–107; Stark, B.P.; Duke, A.J. *Extrusion Reactions*, Pergamon, Elmsford, NY, **1967**, pp. 47–71.

⁵¹³Ried, W.; Wagner, K. *Liebigs Ann. Chem.* **1965**, *681*, 45.

Decarboxylation of β -lactones (see **17-26**) may be regarded as a degenerate example of this reaction. Unsymmetrical diacyl peroxides $\text{RCO}-\text{OO}-\text{COR}'$ lose two molecules of CO_2 when photolyzed in the solid state to give the product RR' .⁵¹⁴ Electrolysis was also used, but yields were lower. This is an alternative to the Kolbe reaction (**11-34**) (see also **17-28** and **17-38**).

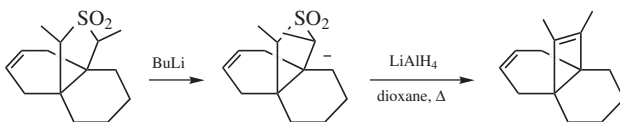

There are no OS references, but see OS **VI**, 418, for a related reaction.

17-36 Extrusion of SO_2

Sulfonyl-extrusion

In a reaction similar to **17-35**, certain sulfones, both cyclic and acyclic,⁵¹⁵ extrude SO_2 on heating or photolysis to give ring-contracted products.⁵¹⁶ An example is the preparation of naphtho(*b*)cyclobutene shown above.⁵¹⁷ In a different kind of reaction, five-membered cyclic sulfones can be converted to cyclobutenes by treatment with butyllithium followed by LiAlH_4 ,⁵¹⁸ for example,

This method is most successful when both the α and α' position of the sulfone bear alkyl substituents (see also **17-20**). Treating four-membered ring sultams with SnCl_2 led to aziridine products via loss of SO_2 .⁵¹⁹

17-37 The Story Synthesis

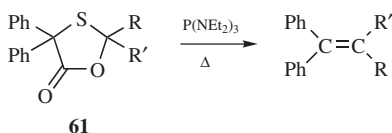

When cycloalkylidene peroxides (e.g., **60**) are heated in an inert solvent (e.g., decane), extrusion of CO₂ takes place; the products are the cycloalkane containing three carbon atoms less than the starting peroxide and the lactone containing two carbon atoms less⁵²⁰ (the *Story synthesis*).⁵²¹ The two products are formed in comparable yields, usually ~15–25% each. Although the yields are low, the reaction is useful because there are not many other ways to prepare large rings. The reaction is versatile, having been used to prepare rings of every size from 8 to 33 members.

Both dimeric and trimeric cycloalkylidene peroxides can be synthesized⁵²² by treatment of the corresponding cyclic ketones with H₂O₂ in acid solution.⁵²³ The trimeric peroxide is formed first and is subsequently converted to the dimeric compound.⁵²⁴

17-38 Alkene Synthesis by Twofold Extrusion

Carbon dioxide, thio-extrusion

4,4-Diphenylthiooxathiolan-5-ones (**61**) give good yields of the corresponding alkenes when heated with tris(diethylamino)phosphine.⁵²⁵ This reaction is an

Rearrangements

In a rearrangement reaction a group moves from one atom to another in the same molecule.¹ Most are migrations from an atom to an adjacent one (called 1,2-shifts), but some are over longer distances. The migrating group (W)

may move with its electron pair (these can be called *nucleophilic* or *anionotropic* rearrangements; the migrating group can be regarded as a nucleophile), without its electron pair (*electrophilic* or *cationotropic* rearrangements; in the case of migrating hydrogen, *prototropic* rearrangements), or with just one electron (free-radical rearrangements). The atom A is called the *migration origin* and B is the *migration terminus*. However, there are some rearrangements that do not lend themselves to neat categorization in this manner. Among these are those with cyclic transition states (18-27–18-36).

As we will see, nucleophilic 1,2-shifts are much more common than electrophilic or free-radical 1,2-shifts. The reason for this can be seen by a consideration of the transition states (or in some cases intermediates) involved. We represent the transition state or intermediate for all three cases by **1**, in which the two-electron

¹For books, see de Mayo, P. *Rearrangements in Ground and Excited States*, 3 vols., Academic Press, NY, 1980; Stevens, T.S.; Watts, W.E. *Selected Molecular Rearrangements*, Van Nostrand-Reinhold, Princeton, NJ, 1973. For a review of many of these rearrangements, see Collins, C.J.; Eastham, J.F., in Patai, S. *The Chemistry of the Carbonyl Group*, Vol. 1, Wiley, NY, 1966, pp. 761–821. See also, the series *Mechanisms of Molecular Migrations*.

A–W bond overlaps with the orbital on atom B, which contains zero, one, and two electrons, in the case of nucleophilic, free-radical, and electrophilic migration, respectively. The overlap of these orbitals gives rise to three new orbitals, which have an energy relationship similar to those on p. 72 (one bonding and two degenerate antibonding orbitals). In a nucleophilic migration, where only two electrons are involved, both can go into the bonding orbital and **1** is a low-energy transition state; but in a free-radical or electrophilic migration, there are, respectively, three or four electrons that must be accommodated, and antibonding orbitals must be occupied. It is not surprising therefore that, when 1,2-electrophilic or free-radical shifts are found, the migrating group W is usually aryl or some other group that can accommodate the extra one or two electrons and thus effectively remove them from the three-membered transition state or intermediate (see **41** on p. 1577).

In any rearrangement, we can in principle distinguish between two possible modes of reaction: In one of these, the group W becomes completely detached from A and may end up on the B atom of a different molecule (*intermolecular* rearrangement); in the other W goes from A to B in the *same* molecule (*intramolecular* rearrangement), in which case there must be some continuing tie holding W to the A–B system, preventing it from coming completely free. Strictly speaking, only the intramolecular type fits our definition of a rearrangement, but the general practice, which is followed here, is to include under the title “rearrangement” all net rearrangements whether they are inter- or intramolecular. It is usually not difficult to tell whether a given rearrangement is inter- or intramolecular. The most common method involves the use of *crossover* experiments. In this type of experiment, rearrangement is carried out on a mixture of W–A–B and V–A–C, where V is closely related to W (say, methyl vs. ethyl) and B to C. In an intramolecular process only A–B–W and A–C–V are recovered, but if the reaction is intermolecular, then not only will these two be found, but also A–B–V and A–C–W.

MECHANISMS

Nucleophilic Rearrangements²

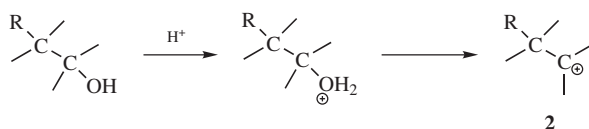

Broadly speaking, such rearrangements consist of three steps, of which the actual migration is the second:

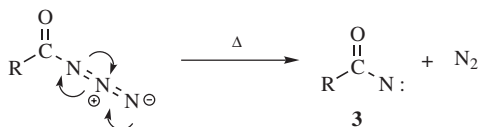

²For reviews, see Vogel, P. *Carbocation Chemistry*; Elsevier, NY, **1985**, pp. 323–372; Shubin, V.G. *Top. Curr. Chem.* **1984**, 116/117, 267; Saunders, M.; Chandrasekhar, J.; Schleyer, P.v.R., in de Mayo, P. *Rearrangements in Ground and Excited States*, Vol. 1, Academic Press, NY, **1980**, pp. 1–53; Kirmse, W. *Top. Curr. Chem.* **1979**, 80, 89. For reviews of rearrangements in vinylic cations, see Shchegolev, A.A.; Kanishchev, M.I. *Russ. Chem. Rev.* **1981**, 50, 553; Lee, C.C. *Isot. Org. Chem.* **1980**, 5, 1.

This process has been called the *Whitmore 1,2-shift*.³ Since the migrating group carries the electron pair with it, the migration terminus B must be an atom with only six electrons in its outer shell (an open sextet). The first step therefore is creation of a system with an open sextet. Such a system can arise in various ways, but two of these are the most important:

1. *Formation of a Carbocation.* These can be formed in a number of ways (see p. 247), but one of the most common methods when a rearrangement is desired is the acid treatment of an alcohol to give **2** from an intermediate oxonium ion. These two steps are of course the same as the first two steps of the S_N1cA or the $E1$ reactions of alcohols.

2. *Formation of a Nitrene.* The decomposition of acyl azides is one of several ways in which acyl nitrenes **3** are formed (see p. 293). After the migration has taken place, the atom at the migration origin (A) must necessarily have an open sextet. In the third step, this atom acquires an octet. In the case of carbocations, the most common third steps are combinations with a nucleophile (rearrangement with substitution) and loss of H^+ (rearrangement with elimination).

Although we have presented this mechanism as taking place in three steps, and some reactions do take place in this way, in many cases two or all three steps are simultaneous. For example, in the nitrene example above, as the R migrates, an electron pair from the nitrogen moves into the C–N bond to give a stable isocyanate, **4**.

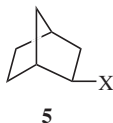

In this example, the second and third steps are simultaneous. It is also possible for the second and third steps to be simultaneous even when the “third” step involves more than just a simple motion of a pair of electrons. Similarly, there are many reactions in which the first two steps are simultaneous; that is, there is no actual formation of a species, such as **2** or **3**. In these instances, it may be said that

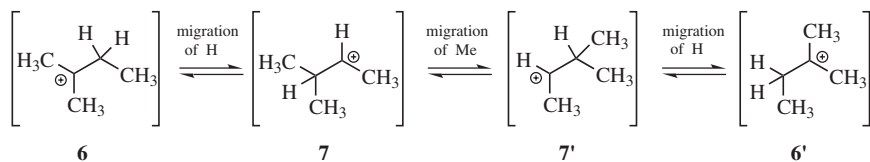

³It was first postulated by Whitmore, F.C. *J. Am. Chem. Soc.* **1932**, *54*, 3274.

R assists in the removal of the leaving group, with migration of R and the removal of the leaving group taking place simultaneously. Many investigations have been carried out in attempts to determine, in various reactions, whether such intermediates as **2** or **3** actually form, or whether the steps are simultaneous (see, e.g., the discussions on pp. 1381, 1563), but the difference between the two possibilities is often subtle, and the question is not always easily answered.⁴

Evidence for this mechanism is that rearrangements of this sort occur under conditions where we have previously encountered carbocations: S_N1 conditions, Friedel–Crafts alkylation, and so on. Solvolysis of neopentyl bromide leads to rearrangement products, and the rate increases with increasing ionizing power of the solvent but is unaffected by concentration of base,⁵ so that the first step is carbocation formation. The same compound under S_N2 conditions gave no rearrangement, but only ordinary substitution, though slowly. Thus with neopentyl bromide, formation of a carbocation leads only to rearrangement. Carbocations usually rearrange to more stable carbocations. Thus the direction of rearrangement is usually primary → secondary → tertiary. Neopentyl (Me₃CCH₂), neophyl (PhCMe₂CH₂), and norbornyl (e.g., **5**) type systems are especially prone to carbocation rearrangement reactions. It has been shown that the rate of migration increases with the degree of electron deficiency at the migration terminus.⁶

We have previously mentioned (p. 236) that stable tertiary carbocations can be obtained, in solution, at very low temperatures. The NMR studies have shown that when these solutions are warmed, rapid migrations of hydride and of alkyl groups take place, resulting in an equilibrium mixture of structures.⁷ For example, the *tert*-pentyl cation (**5**)⁸ equilibrates as follows:

⁴The IUPAC designations depend on the nature of the steps. For the rules, see Guthrie, R.D. *Pure Appl. Chem.* **1989**, *61*, 23, 44–45.

Carbocations that rearrange to give products of identical structure (e.g., $6 \rightleftharpoons 6', 7 \rightleftharpoons 7'$) are called *degenerate carbocations* and such rearrangements are *degenerate rearrangements*. Many examples are known.⁹

The Actual Nature of the Migration

Most nucleophilic 1,2-shifts are intramolecular. The W group does not become free, but always remains connected in some way to the substrate. Apart from the evidence from crossover experiments, the strongest evidence is that when the W group is chiral, the configuration is *retained* in the product. For example, (+)-PhCHMeCOOH was converted to (–)-PhCHMeNH₂ by the Curtius (**18-14**), Hofmann (**18-13**), Lossen (**18-15**), and Schmidt (**18-16**) reactions.¹⁰ In these reactions, the extent of retention varied from 95.8 to 99.6%. Retention of configuration in the migrating group has been shown many times since.¹¹ Another experiment demonstrating retention was the

easy conversion of **8** to **9**.¹¹ Neither inversion nor racemization could take place at a bridgehead. There is much other evidence that retention of configuration usually occurs in W, and inversion never.¹² However, this is not the state of affairs at A and B. In many reactions, of course, the structure of W–A–B is such that the product has only one steric possibility at A or B or both, and in most of these cases nothing can be learned. But in cases where the steric nature of A or B can be investigated, the results are mixed. It has been shown that either inversion or racemization can occur at A or B. Thus the following conversion proceeded with inversion at B:¹³

and inversion at A has been shown in other cases.¹⁴ However, in many other cases, racemization occurs at A or B.¹⁵ It is not always necessary for the product to have two steric possibilities in order to investigate the stereochemistry at A or B. Thus, in most Beckmann rearrangements (18-17), only the group trans (usually called *anti*) to the hydroxyl group migrates:

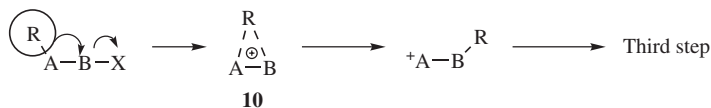

showing inversion at B.

This information tells us about the degree of concertedness of the three steps of the rearrangement. First consider the migration terminus B. If racemization is found at B, it is probable that the first step takes place before the second and that a positively charged carbon (or other sextet atom) is present at B:

With respect to B this is an $\text{S}_{\text{N}}1$ -type process. If inversion occurs at B, it is likely that the first two steps are concerted, that a carbocation is *not* an intermediate, and that the process is $\text{S}_{\text{N}}2$ -like:

In this case, participation by R assists in removal of X in the same way that neighboring groups do (p. 446). Indeed, R *is* a neighboring group here. The only difference is that, in the case of the neighboring-group mechanism of nucleophilic substitution, R never becomes detached from A, while in a rearrangement the bond between R and A is broken. In either case, the anchimeric assistance results in an increased rate of reaction. Of course, for such a process to take place, R must be in a favorable geometrical position (R and X antiperiplanar). Intermediate **10** may be a true intermediate or only a transition state, depending on what migrates. In certain cases of the $\text{S}_{\text{N}}1$ -type process, it is possible for migration to take place with net retention of configuration at the migrating terminus because of conformational effects in the carbocation.¹⁶

We may summarize a few conclusions:

1. The $\text{S}_{\text{N}}1$ -type process occurs mostly when B is a tertiary atom or has one aryl group and at least one other alkyl or aryl group. In other cases, the $\text{S}_{\text{N}}2$ -type

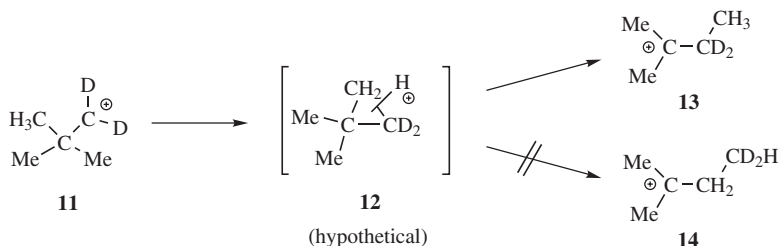

¹⁴See Meerwein, H.; van Emster, K. *Ber.* **1920**, *53*, 1815; **1922**, *55*, 2500; Meerwein, H.; Gérard, L. *Liebigs Ann. Chem.* **1923**, *435*, 174.

¹⁵For example, see Winstein, S.; Morse, B.K. *J. Am. Chem. Soc.* **1952**, *74*, 1133.

¹⁶Collins, C.J.; Benjamin, B.M. *J. Org. Chem.* **1972**, *37*, 4358, and references cited therein.

process is more likely. Inversion of configuration (indicating an S_N2 -type process) has been shown for a neopentyl substrate by the use of the chiral neopentyl-1-*d* alcohol.¹⁷ On the other hand, there is other evidence that neopentyl systems undergo rearrangement by a carbocation (S_N1 -type) mechanism.¹⁸

2. The question as to whether **10** is an intermediate or a transition state has been much debated. When R is aryl or vinyl, then **10** is probably an intermediate and the migrating group lends anchimeric assistance¹⁹ (see p. 459 for resonance stabilization of this intermediate, when R is aryl). When R is alkyl, **10** is a protonated cyclopropane (edge- or corner-protonated; see p. 1026). There is much evidence that in simple migrations of a methyl group, the bulk of the products formed do not arise from protonated cyclopropane *intermediates*. Evidence for this statement has already been given (p. 467). Further evidence was obtained from experiments involving labeling.

Rearrangement of the neopentyl cation labeled with deuterium in the 1 position (**11**) gave only *tert*-pentyl products with the label in the 3 position (derived from **13**), though if **12** were an intermediate, the cyclopropane ring could just as well cleave the other way to give *tert*-pentyl derivatives labeled in the 4 position (derived from **14**).²⁰ Another experiment that led to the same conclusion was the generation, in several ways, of $\text{Me}_3\text{C}^{13}\text{CH}_2^+$. In this case, the only *tert*-pentyl products isolated were labeled in C-3, that is, $\text{Me}_2\text{C}^+-^{13}\text{CH}_2\text{CH}_3$ derivatives; no derivatives of $\text{Me}_2\text{C}^+-\text{CH}_2^{13}\text{CH}_3$ were found.²¹

Although the bulk of the products are not formed from protonated cyclopropane intermediates, there is considerable evidence that at least in 1-propyl

systems, a small part of the product can in fact arise from such intermediates.²² Among this evidence is the isolation of 10–15% cyclopropanes (mentioned on p. 467). Additional evidence comes from propyl cations generated by diazotization of labeled amines ($\text{CH}_3\text{CH}_2\text{CD}_2^+$, $\text{CH}_3\text{CD}_2\text{CH}_2^+$, $\text{CH}_3\text{CH}_2^{14}\text{CH}_2^+$), where isotopic distribution in the products indicated that a small amount ($\sim 5\%$) of the product had to be formed from protonated cyclopropane intermediates, for example,²³

Even more scrambling was found in trifluoroacetylolysis of 1-propyl-1-¹⁴C-mercuric perchlorate.²⁴ However, protonated cyclopropane intermediates accounted for <1% of the products from diazotization of labeled isobutylamine²⁵ and from formolysis of labeled 1-propyl tosylate.²⁶

It is likely that protonated cyclopropane transition states or intermediates are also responsible for certain non-1,2 rearrangements. For example, in super acid solution, the ions **15** and **17** are in equilibrium. It is not possible for these to interconvert solely by 1,2-alkyl or hydride shifts unless primary carbocations (which are highly unlikely) are intermediates. However, the reaction can be explained²⁷ by postulating that (in the forward reaction) it is the 1,2 bond

of the intermediate or transition state **16** that opens up rather than the 2,3 bond, which is the one that would open if the reaction were a normal 1,2-shift of a methyl group. In this case, opening of the 1,2 bond produces a tertiary cation, while opening of the 2,3 bond would give a secondary cation. (In the reaction **17** \rightarrow **15**, it is of course the 1,3 bond that opens).

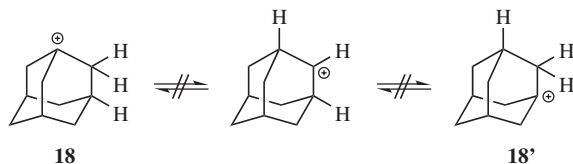

3. There has been much discussion of H as migrating group. There is no conclusive evidence that **10** in this case is or is not a true intermediate, although both positions have been argued (see p. 467).

The stereochemistry at the migration origin A is less often involved, since in most cases it does not end up as a tetrahedral atom; but when there is inversion here, there is an S_N2 -type process at the beginning of the migration. This may or may not be accompanied by an S_N2 process at the migration terminus B:

In some cases, it has been found that, when H is the migrating species, the configuration at A may be *retained*.²⁸

There is evidence that the configuration of the molecule may be important even where the leaving group is gone long before migration takes place. For example, the 1-adamantyl cation (**18**) does not equilibrate intramolecularly, even at temperatures up to 130°C,²⁹ though open-chain (e.g., **6** \rightleftharpoons **6'**) and cyclic tertiary

carbocations undergo such equilibration at 0°C or below. On the basis of this and other evidence it has been concluded that for a 1,2-shift of hydrogen or methyl to proceed as smoothly as possible, the vacant *p* orbital of the carbon bearing the positive charge and the sp^3 orbital carrying the migrating group must be coplanar,²⁹ which is not possible for **18**.

Migratory Aptitudes³⁰

In many reactions, there is no question about which group migrates. For example, in the Hofmann, Curtius, and similar reactions there is only one possible migrating group in each molecule, and one can measure migratory aptitudes only by comparing the relative rearrangement rates of different compounds. In other instances, there are two or more potential migrating groups, but which migrates is settled by the geometry of the molecule. The Beckmann rearrangement (**18-17**) provides an example. As we have seen, only the group trans to the OH migrates. In compounds whose geometry is not restricted in this manner, there still may be eclipsing effects (see p. 1502), so that the choice of migrating group is largely determined by which group is in the right place in the most stable conformation of the molecule.³¹ However, in some reactions, especially the Wagner–Meerwein (**18-1**) and the pinacol (**18-2**) rearrangements, the molecule may contain several groups that, geometrically at least, have approximately equal chances of migrating, and these reactions have often been used for the direct study of relative migratory aptitudes. In the pinacol rearrangement, there is the additional question of which OH group leaves and which does not, since a group can migrate only if the OH group on the *other* carbon is lost.

We deal with the second question first. To study this question, the best type of substrate to use is one of the form $\begin{matrix} R_2C & - & CR'_2 \\ | & & | \\ OH & & OH \end{matrix}$, since the only thing that determines migratory aptitude is which OH group comes off. Once the OH group is gone, the migrating group is determined. As might be expected, the OH that leaves is the one whose loss gives rise to the more stable carbocation. Thus 1,1-diphenylethanediol (**19**) gives diphenylacetaldehyde (**20**), not phenylacetophenone (**21**). Obviously, it does not matter in this case whether phenyl has a greater

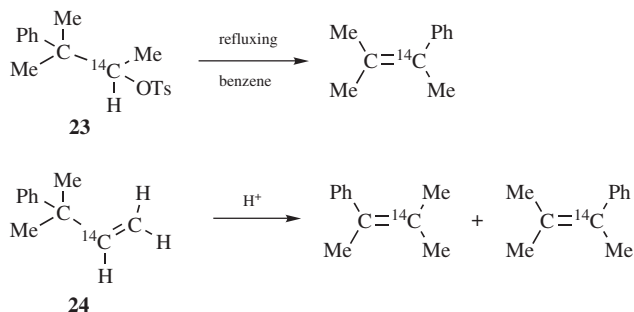

inherent migratory aptitude than hydrogen or not. Only the hydrogen can migrate because **22** is not formed. As we know, carbocation stability is enhanced by

³⁰For discussions, see Koptuyg, V.A.; Shubin, V.G. *J. Org. Chem. USSR* **1980**, *16*, 1685; Wheland, G.W. *Advanced Organic Chemistry*, 3rd ed., Wiley, NY, **1960**, pp. 573–597.

³¹For a discussion, see Cram, D.J., in Newman, M.S. *Steric Effects in Organic Chemistry*, Wiley, NY, **1956**, pp. 270–276. For an interesting example, see Nickon, A.; Weglein, R.C. *J. Am. Chem. Soc.* **1975**, *97*, 1271.

groups in the order aryl > alkyl > hydrogen, and this normally determines which side loses the OH group. However, exceptions are known, and which group is lost may depend on the reaction conditions (e.g., see the reaction of **53**, p. 1586).

In order to answer the question about inherent migratory aptitudes, the obvious type of substrate to use (in the pinacol rearrangement) is $\begin{matrix} R'RC-CRR' \\ | \quad | \\ OH \quad OH \end{matrix}$, since the same carbocation is formed no matter which OH leaves, and it would seem that a direct comparison of the migratory tendencies of R and R' is possible. On closer inspection, however, we can see that several factors are operating. Apart from the question of possible conformational effects, already mentioned, there is also the fact that whether the group R or R' migrates is determined not only by the relative inherent migrating abilities of R and R', but also by whether the group that does *not* migrate is better at stabilizing the positive charge that will now be found at the migration origin.³² Thus, migration of R gives rise to the cation $R'C^+(OH)CR_2R'_2$, while migration of R' gives the cation $R^+C(OH)CRR'_2$, and these cations have different stabilities. It is possible that in a given case R might be found to migrate less than R', not because it actually has a lower inherent migrating tendency, but because it is much better at stabilizing the positive charge. In addition to this factor,

migrating ability of a group is also related to its capacity to render anchimeric assistance to the departure of the nucleofuge. An example of this effect is the finding that in the decomposition of tosylate **23** only the phenyl group migrates, while in acid treatment of the corresponding alkene **24**, there is competitive migration of both methyl and phenyl (in these reactions ^{14}C labeling is necessary to determine which group has migrated).³³ Both **23** and **24** give the same carbocation; the differing results must be caused by the fact that in **23** the phenyl group can assist the leaving group, while no such process is possible for **24**. This example clearly illustrates the difference between migration to a relatively

³²For example, see McCall, M.J.; Townsend, J.M.; Bonner, W.A. *J. Am. Chem. Soc.* **1975**, *97*, 2743; Brownbridge, P.; Hodgson, P.K.G.; Shepherd, R.; Warren, S. *J. Chem. Soc. Perkin Trans. 1* **1976**, 2024.

³³Grimaud, J.; Laurent, A. *Bull. Soc. Chim. Fr.* **1967**, 3599.

free terminus and one that proceeds with the migrating group lending anchimeric assistance.³⁴

It is not surprising therefore that clear-cut answers as to relative migrating tendencies are not available. More often than not migratory aptitudes are in the order aryl > alkyl, but exceptions are known, and the position of hydrogen in this series is often unpredictable. In some cases, migration of hydrogen is preferred to aryl migration; in other cases, migration of alkyl is preferred to that of hydrogen. Mixtures are often found and the isomer that predominates often depends on conditions. For example, the comparison between methyl and ethyl has been made many times in various systems, and in some cases methyl migration and in others ethyl migration has been found to predominate.³⁵ However, it can be said that among aryl migrating groups, electron-donating substituents in the para and meta positions increase the migratory aptitudes, while the same substituents in the ortho positions decrease them. Electron-withdrawing groups decrease migrating ability in all positions. The following are a few of the relative migratory aptitudes determined for aryl groups by Bachmann and Ferguson:³⁶ *p*-anisyl, 500; *p*-tolyl, 15.7; *m*-tolyl, 1.95; phenyl, 1.00; *p*-chlorophenyl, 0.7; *o*-anisyl, 0.3. For the *o*-anisyl group, the poor migrating ability probably has a steric cause, while for the others there is a fair correlation with activation or deactivation of electrophilic aromatic substitution, which is what the process is with respect to the benzene ring. It has been reported that at least in certain systems acyl groups have a greater migratory aptitude than alkyl groups.³⁷

Memory Effects³⁸

Solvolysis of the endo bicyclic compound **25** (X = ONs, p. 497, or Br) gave mostly the bicyclic allylic alcohol, **28**, along with a smaller amount of the tricyclic alcohol **32**, while solvolysis of the exo isomers, **29**, gave mostly **32**, with smaller amounts of **28**.³⁹ Thus the two isomers gave entirely different ratios of products, although

³⁴A number of studies of migratory aptitudes in the dienone-phenol rearrangement (**18-5**) are in accord with the above. For a discussion, see Fischer, A.; Henderson, G.N. *J. Chem. Soc., Chem. Commun.* **1979**, 279, and references cited therein. See also, Palmer, J.D.; Waring, A.J. *J. Chem. Soc. Perkin Trans. 2* **1979**, 1089; Marx, J.N.; Hahn, Y.P. *J. Org. Chem.* **1988**, 53, 2866.

³⁵For examples, see Cram, D.J.; Knight, J.D. *J. Am. Chem. Soc.* **1952**, 74, 5839; Stiles, M.; Mayer, R.P. *J. Am. Chem. Soc.* **1959**, 81, 1497; Heidke, R.L.; Saunders, Jr., W.H. *J. Am. Chem. Soc.* **1966**, 88, 5816; Dubois, J.E.; Bauer, P. *J. Am. Chem. Soc.* **1968**, 90, 4510, 4511; Bundel', Yu. G.; Levina, I.Yu.; Reutov, O.A. *J. Org. Chem. ³⁸For a review, see Berson, J.A. *Angew. Chem. Int. Ed.* **1968**, 7, 779.

³⁹Berson, J.A.; Poonian, M.S.; Libbey, W.J. *J. Am. Chem. Soc.* **1969**, 91, 5567; Berson, J.A.; Donald, D.S.; Libbey, W.J. *J. Am. Chem. Soc.* **1969**, 91, 5580; Berson, J.A.; Wege, D.; Clarke, G.M.; Bergman, R.G. *J. Am. Chem. Soc.* **1969**, 91, 5594, 5601.

the carbocation initially formed (**26** or **30**) seems to be the same for each. In the case of **26**, a second rearrangement (a shift of the 1,7 bond) follows, while with **30** what follows is an intramolecular addition of the positive carbon to the double bond.

It seems as if **26** and **30** “remember” how they were formed before they go on to give the second step. Such effects are called *memory effects* and other such cases are known.⁴⁰ The causes of these effects are not well understood, though there has been much discussion. One possible cause is differential solvation of the apparently identical ions **26** and **30**. Other possibilities are (1) that the ions have geometrical structures that are twisted in opposite senses (e.g., a twisted **30** might have its positive carbon closer to the double

bond than a twisted **26**); (2) that ion pairing is responsible;⁴¹ and (3) that nonclassical carbocations are involved.⁴² One possibility that has been ruled out is that the steps **25** → **26** → **27** and **29** → **30** → **31** are concerted, so that **26** and **30** never exist at all. This possibility has been excluded by several kinds of evidence, including the fact that **25** gives not only **28**, but also some **32**; and **29** gives some **28**

⁴⁰For examples of memory effects in other systems, see Berson, J.A.; Luibrand, R.T.; Kundu, N.G.; Morris, D.G. *J. Am. Chem. Soc.* **1971**, *93*, 3075; Collins, C.J. *Acc. Chem. Res.* **1971**, *4*, 315; Collins, J.A.; Glover, I.T.; Eckart, M.D.; Raaen, V.F.; Benjamin, B.M.; Benjaminov, B.S. *J. Am. Chem. Soc.* **1972**, *94*, 899; Svensson, T. *Chem. Scr.* **1974**, *6*, 22.

⁴²See, for example, Seybold, G.; Vogel, P.; Saunders, M.; Wiberg, K.B. *J. Am. Chem. Soc.* **1973**, *95*, 2045; Kirmse, W.; Günther, B. *J. Am. Chem. Soc.* **1978**, *100*, 3619.

along with **32**. This means that some of the **26** and **30** ions interconvert, a phenomenon known as *leakage*.

Longer Nucleophilic Rearrangements

The question as to whether a group can migrate with its electron pair from A to C in W–A–B–C or over longer distances has been much debated. Although claims have been made that alkyl groups can migrate in this way, the evidence is that such migration is extremely rare, if it occurs at all. One experiment that demonstrated this was the generation of the 3,3-dimethyl-1-butyl cation $\text{Me}_3\text{CCH}_2\text{CH}_2^+$. If 1,3-methyl migrations are possible, this cation would appear to be a favorable substrate, since such a migration would convert a primary cation into the tertiary 2-methyl-2-pentyl cation $\text{Me}_2\text{CCH}_2\text{CH}_2\text{CH}_3$, while the only possible 1,2 migration (of hydride) would give only a secondary cation. However, no products arising from the 2-methyl-2-pentyl cation were found, the only rearranged products being those formed by the 1,2 hydride migration.⁴³ 1,3 Migration of bromine has been reported.⁴⁴

However, most of the debate over the possibility of 1,3 migrations has concerned not methyl or bromine, but 1,3 hydride shifts.⁴⁵ There is no doubt that *apparent* 1,3 hydride shifts take place (many instances have been found), but the question is whether they are truly direct hydride shifts or whether they occur by another

mechanism. There are at least two ways in which indirect 1,3-hydride shifts can take place: (1) by successive 1,2-shifts or (2) through the intervention of protonated cyclopropanes (see p. 1565). A direct 1,3-shift would have the transition state **A**, while the transition state for a 1,3-shift involving a protonated cyclopropane intermediate would resemble **B**. The evidence is that most reported 1,3 hydride shifts are actually the result of successive 1,2 migrations,⁴⁶ but that in some cases small amounts of products cannot be accounted for in this way. For example, the reaction of 2-methyl-1-butanol with KOH and bromoform gave a mixture of alkenes, nearly all of which could have arisen from simple

⁴⁵For a review, see Fry, J.L.; Karabatsos, G.J., in Olah, G.A.; Schleyer, P.v.R. *Carbonium Ions*, Vol. 2, Wiley, NY, **1970**, p. 527.

⁴⁶For example, see Bundel', Yu.G.; Levina, I.Yu.; Krzhizhevskii, A.M.; Reutov, O.A. *Doklad. Chem.* **1968**, *181*, 583; Fărcașiu, D.; Kascheres, C.; Schwartz, L.H. *J. Am. Chem. Soc.* **1972**, *94*, 180; Kirmse, W.; Knist, J.; Ratajczak, H. *Chem. Ber.* **1976**, *109*, 2296.

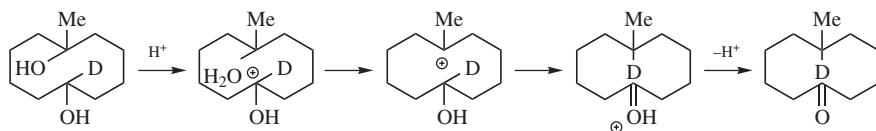

elimination or 1,2-shifts of hydride or alkyl. However, 1.2% of the product was **33**.⁴⁷

Hypothetically, **33** could have arisen from a 1,3-shift (direct or through a protonated cyclopropane) or from two successive 1,2-shifts:

However, the same reaction applied to 2-methyl-2-butanol gave no **33**, which demonstrated that **36** was not formed from **35**. The conclusion made was that **36** was formed directly from **34**. This experiment does not answer the question as to whether **36** was formed by a direct shift or through a protonated cyclopropane, but from other evidence⁴⁸ it appears that 1,3 hydride shifts that do not result from successive 1,2 migrations usually take place through protonated cyclopropane intermediates (which, as we saw on p. 1565, account for only a small percentage of the product in any case). However, there is evidence that direct 1,3 hydride shifts by way of **A** may take place in super acid solutions.⁴⁹ Although direct nucleophilic rearrangements over distances >1,2 are rare (or perhaps nonexistent) when the migrating atom or group must move along a chain, this is not so for a shift across a ring of 8–11 members. Many such transannular rearrangements are known.⁵⁰ Several examples are given on p. 223. This is the mechanism of one of these:⁵¹

⁵¹Prelog, V.; Küng, W. *Helv. Chim. Acta* **1956**, *39*, 1394.

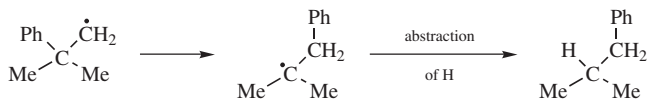

It is noteworthy that the *methyl* group does not migrate in this system. It is generally true that alkyl groups do not undergo transannular migration.⁵² In most cases, it is hydride that undergoes this type of migration, though a small amount of phenyl migration has also been shown.⁵³

Free-Radical Rearrangements⁵⁴

1,2-Free-radical rearrangements are much less common than the nucleophilic type previously considered, for the reasons mentioned on p. 1559. Where they do occur, the general pattern is similar. There must first be generation of a free radical, and then the actual migration in which the migrating group moves with one electron:

Finally, the new free radical must stabilize itself by a further reaction. The order of radical stability leads us to predict that here too, as with carbocation rearrangements, any migrations should be in the order primary \rightarrow secondary \rightarrow tertiary, and that the logical place to look for them should be in neopentyl and neophyl systems. The most common way of generating free radicals for the purpose of detection of rearrangements is by decarbonylation of aldehydes (14-32). In this manner, it was found that neophyl radicals *do* undergo rearrangement. Thus, PhCMe₂CH₂CHO treated with di-*tert*-butyl peroxide gave about equal amounts of the normal product PhCMe₂CH₃ and the product arising from migration of phenyl.⁵⁵

⁵²For an apparent exception, see Fărcașiu, D.; Seppo, E.; Kizirian, M.; Ledlie, D.B.; Sevin, A. *J. Am. Chem. Soc.* **1989**, *111*, 8466.

Many other cases of free-radical migration of aryl groups have been found.⁵⁶ Intramolecular radical rearrangements are known.⁵⁷ The C-4 radicals of α - and β -thujone undergo two distinct rearrangement reactions, and it has been proposed that these could serve as simultaneous, but independent radical clocks.⁵⁸

A 1,2-shift has been observed in radicals bearing an OCOR group at the β -carbon where the oxygen group migrates as shown in the interconversion of **37** and **38**. This has been proven by ¹⁸O isotopic labeling experiments⁵⁹ and other mechanistic explorations.⁶⁰ A similar rearrangement was observed with phosphatoxy alkyl radicals, such as **39**.⁶¹ A 1,2-shift of hydrogen atoms has been observed in aryl radicals.⁶²

A C \rightarrow N 1,2-aryl rearrangement was observed when alkyl azides were treated with *n*-Bu₃SnH, proceeding via an C-N[•]-SnBu₃ species to give an imine.⁶³

It is noteworthy that the extent of migration is much less than with corresponding carbocations: Thus in the example given, there was only ~50% migration, whereas the carbocation would have given much more. Also noteworthy is that there was no migration of the methyl group. In general, it may be said that free-radical migration of alkyl groups does not occur at ordinary temperatures. Many attempts have been made to detect such migration on the traditional neopentyl and bornyl types of substrates. However, alkyl migration is not observed, even in substrates where the corresponding carbocations undergo facile rearrangement.⁶⁴ Another type of migration that is very common for carbocations, but not observed

⁵⁶For example, see Curtin, D.Y.; Hurwitz, M.J. *J. Am. Chem. Soc.* **1952**, *74*, 5381; Wilt, J.K.; Philip, H. *J. Org. for free radicals, is 1,2 migration of hydrogen. We confine ourselves to a few examples of the lack of migration of alkyl groups and hydrogen:

1. 3,3-Dimethylpentanal (EtCMe₂CH₂CHO) gave no rearranged products on decarbonylation.⁶⁵
2. Addition of RSH to norbornene gave only *exo*-norbornyl sulfides, though **40** is an intermediate, and the corresponding carbocation cannot be formed without rearrangement.⁶⁶

3. The cubylcarbiny radical did not rearrange to the 1-homocubyl radical, though doing so would result in a considerable decrease in strain.⁶⁷

4. It was shown⁶⁸ that no rearrangement of isobutyl radical to *tert*-butyl radical (which would involve the formation of a more stable radical by a hydrogen shift) took place during the chlorination of isobutane.

However, 1,2 migration of alkyl groups has been shown to occur in certain *diradicals*.⁶⁹ For example, the following rearrangement has been established by tritium labeling.⁷⁰

In this case, the fact that migration of the methyl group leads directly to a compound in which all electrons are paired undoubtedly contributes to the driving force of the reaction.

Chem.* **1966**, *31*, 2087; Gajewski, J.J.; Burka, L.T. *J. Am. Chem. Soc.* **1972**, *94*, 8857, 8860, 8865; Adam, W.; Aponte, G.S. *J. Am. Chem. Soc.* **1971**, *93*, 4300.

The fact that aryl groups migrate, but alkyl groups and hydrogen generally do not, leads to the proposition that **41**, in which the odd electron is not found in the three-membered ring, may be an intermediate. There has been much controversy on this point, but the bulk of the evidence indicates that **41** is a transition state, not an intermediate.⁷¹ Among the evidence is the failure to observe **41** either by ESR⁷² or CIDNP.⁷³ Both of these techniques can detect free radicals with extremely short lifetimes (pp. 266–268).⁷⁴

**41**

Besides aryl, vinylic⁷⁵ and acetoxy groups⁷⁶ also migrate. Vinylic groups migrate by way of a cyclopropylcarbinyl radical intermediate (**42**),⁷⁷ while the migration of acetoxy groups may involve the charge-separated structure shown.⁷⁸ Thermal isomerization of 1-(3-butenyl)cyclopropane at 415°C leads to bicyclo[2.2.1]heptane.⁷⁹ Migration has been observed for chloro (and to a much lesser extent

bromo) groups. For example, in the reaction of $\text{Cl}_3\text{CCH}=\text{CH}_2$ with bromine under the influence of peroxides, the products were 47% $\text{Cl}_3\text{CCHBrCH}_2\text{Br}$

⁷¹For molecular-orbital calculations indicating that **41** is an intermediate, see Yamabe, S. *Chem. Lett.* **1989**, 1523.

⁷⁹Baldwin, J.E.; Burrell, R.C.; Shukla, R. *Org. Lett.* **2002**, *4*, 3305.

(the normal addition product) and 53% $\text{BrCCl}_2\text{CHClCH}_2\text{Br}$, which arose by rearrangement:

In this particular case, the driving force for the rearrangement is the particular stability of dichloroalkyl free radicals. Nesmeyanov, Freidlina, and co-workers have extensively studied reactions of this sort.⁸⁰ It has been shown that the 1,2 migration of Cl readily occurs if the migration origin is tertiary and the migration terminus primary.⁸¹ Migration of Cl and Br could take place by a transition state in which the odd electron is accommodated in a vacant *d* orbital of the halogen.

Migratory aptitudes have been measured for the phenyl and vinyl groups, and for three other groups, using the system $\text{RCMe}_2\text{CH}_2\cdot \rightarrow \text{Me}_2\dot{\text{C}}\text{CH}_2\text{R}$. These were found to be in the order $\text{R} = \text{H}_2\text{C}=\text{CH}_2 > \text{Me}_3\text{CC}=\text{O} > \text{Ph} > \text{Me}_3\text{C}\equiv\text{C} > \text{CN}$.⁸²

In summary then, 1,2 free-radical migrations are much less prevalent than the analogous carbocation processes, and are important only for aryl, vinylic, acetoxy, and halogen migrating groups. The direction of migration is normally toward the more stable radical, but “wrong-way” rearrangements are also known.⁸³

Despite the fact that hydrogen atoms do not migrate 1,2, longer free-radical migrations of hydrogen are known.⁸⁴ The most common are 1,5-shifts, but 1,6 and longer shifts have also been found. The possibility of 1,3 hydrogen shifts has been much investigated, but it is not certain if any actually occur. If they do they are rare, presumably because the most favorable geometry for $\text{C}\cdots\text{H}\cdots\text{C}$ in the transition state is linear and this geometry cannot be achieved in a 1,3-shift. 1,4-Shifts are definitely known, but are still not very common. These long shifts are best regarded as internal abstractions of hydrogen (for reactions involving them, see 14-6 and 18-40):

Transannular shifts of hydrogen atoms have also been observed.⁸⁵

Carbene Rearrangements⁸⁶

Carbenes can rearrange to alkenes in many cases.⁸⁷ A 1,2-hydrogen shift leads to an alkene, and this is often competitive with insertion reactions.⁸⁸ Benzylchlorocarbene (**43**) rearranges via a 1,2 hydrogen shift to give the alkene.⁸⁹ Similarly, carbene **44** rearranges to alkene **45**, and replacement of H on the α -carbon with D showed a deuterium isotope effect of ~ 5 .⁹⁰ Vinylidene carbene ($\text{H}_2\text{C}=\text{C}:$) rearranges to acetylene.⁹¹ Rearrangement of alkylidene carbene **46** has been calculated to give the highly unstable cyclopentyne (**47**), which cannot be isolated, but can give a [2 + 2]-cycloaddition product when generated in the presence of a simple alkene.⁹² The spiro carbenes undergo rearrangement reactions.⁹³

Electrophilic Rearrangements⁹⁴

Rearrangements in which a group migrates without its electrons are much rarer than the two kinds previously considered, but the general principles are the same. A carbanion (or other negative ion) is created first, and the actual rearrangement step involves migration of a group without its electrons:

The product of the rearrangement may be stable or may react further, depending on its nature (see also, pp. 1585). An *ab initio* study predicts that a [1,2]-alkyl shift in alkyne anions should be facile.⁹⁵

REACTIONS

The reactions in this chapter are classified into three main groups and 1,2-shifts are considered first. Within this group, reactions are classified according to (1) the identity of the substrate atoms A and B and (2) the nature of the migrating group W. In the second group are the cyclic rearrangements. The third group consists of rearrangements that cannot be fitted into either of the first two categories.

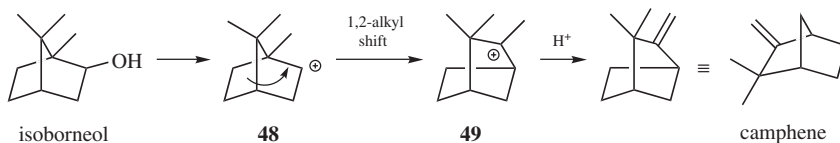

Reactions in which the migration terminus is on an aromatic ring have been treated under aromatic substitution. These are **11-27–11-32**, **11-36**, **13-30–13-32**, and, partially, **11-33**, **11-38**, and **11-39**. Double-bond shifts have also been treated in other chapters, though they may be considered rearrangements (p. \$\$\$, p. \$\$\$, and **12-2**). Other reactions that may be regarded as rearrangements are the Pummerer (**19-83**) and Willgerodt (**19-84**) reactions.

1,2-REARRANGEMENTS

A. Carbon-to-Carbon Migrations of R, H, and Ar

18-1 Wagner–Meerwein and Related Reactions

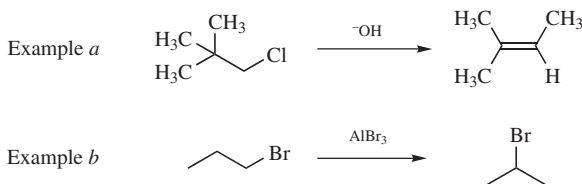

1/Hydro,1/hydroxy-(2/ → 1/alkyl)-migro-elimination, and so on

Wagner–Meerwein rearrangements were first discovered in the bicyclic terpenes, and most of the early development of this reaction was with these compounds.⁹⁶ An example is the conversion of isoborneol to camphene. It fundamentally involves a 1,2 alkyl shift of an intermediate carbocation, such as **48** \rightarrow **49**. When alcohols are treated with acids, simple substitution (e.g., **10-48**) or elimination (**17-1**) usually accounts for most or all of the products. But in many cases, especially where two or three alkyl or aryl groups are on the β carbon, some or all of the product is rearranged. These rearrangements have been called *Wagner–Meerwein rearrangements*, although this term is nowadays reserved for relatively specific transformations, such as isoborneol to camphene and related reactions. As pointed out previously, the carbocation that is a direct product of the rearrangement must stabilize itself, and most often it does this by the loss

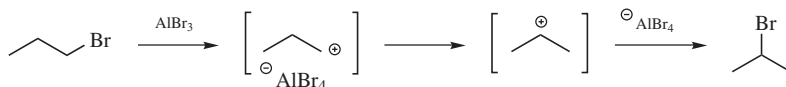

⁹⁶For a review of rearrangements in bicyclic systems, see Hogeveen, H.; van Kruchten, E.M.G.A. *Top. Curr. Chem.* **1979**, *80*, 89. For reviews concerning caranes and pinanes see, respectively, Arbuzov, B.A.; Isaeva, Z.G. *Russ. Chem. Rev.* **1976**, *45*, 673; Banthorpe, D.V.; Whittaker, D. *Q. Rev. Chem. Soc.* **1966**, *20*, 373.

of a hydrogen β to it, so the rearrangement product is usually an alkene.⁹⁷ If there is a choice of protons, Zaitsev's rule (p. 1482) governs the direction, as we might expect. Sometimes a different positive group is lost instead of a proton. Less often, the new carbocation stabilizes itself by combining with a nucleophile instead of losing a proton. The nucleophile may be the water that is the original leaving group, so that the product is a rearranged alcohol, or it may be some other species present (solvent, added nucleophile, etc.). Rearrangement is usually predominant in neopentyl and neophyl types of substrates, and with these types normal nucleophilic substitution is difficult (normal elimination is of course impossible). Under S_N2 conditions, substitution is extremely slow;⁹⁸ and under S_N1 conditions, carbocations are formed that rapidly rearrange. However, free-radical substitution, unaccompanied by rearrangement, can be carried out on neopentyl systems, though, as we have seen (p. 1574), neophyl systems undergo rearrangement as well as substitution.

Examples of Wagner–Meerwein-type rearrangements are found in simpler systems, such as neopentyl chloride (example *a*) and even 1-bromopropane (example *b*). These two examples illustrate the following points:

1. Hydride ion can migrate. In example *b*, it was hydride that shifted, not bromine:

2. The leaving group does not have to be H_2O , but can be any departing species whose loss creates a carbocation, including N_2 from aliphatic diazonium ions⁹⁹ (see the section on leaving groups in nucleophilic substitution, p. 438). Also, rearrangement may follow when the carbocation is created by addition of a proton or other positive species to a double bond. Even alkanes give

⁹⁷For a review of such rearrangements, see Kaupp, G. *Top. Curr. Chem.* **1988**, 146, 57.

⁹⁹For reviews of rearrangements arising from diazotization of aliphatic amines, see, in Patai, S. *The Chemistry of the Amino Group*, Wiley, NY, **1968**, the articles by White, E.H.; Woodcock, D.J. pp. 407–497 (473–483) and by Banthorpe, D.V. pp. 585–667 (586–612).

rearrangements when heated with Lewis acids, provided some species is initially present to form a carbocation from the alkane.

3. Example *b* illustrates that the last step can be substitution instead of elimination.
4. Example *a* illustrates that the new double bond is formed in accord with Zaitsev's rule.

2-Norbornyl cations (see **48**), besides displaying the 1,2-shifts of a CH₂ group previously illustrated for the isborneol → camphene conversion, are also prone to rapid hydride shifts from the 3 to the 2 position (known as 3,2-shifts). These 3,2-shifts usually take place from the exo side;¹⁰⁰ that is, the 3-exo hydrogen migrates to the 2-exo position.¹⁰¹ This stereoselectivity is analogous to the behavior we have previously seen for norbornyl

systems, namely, that nucleophiles attack norbornyl cations from the exo side (p. 461) and that addition to norbornenes is also usually from the exo direction (p. 1023).

For rearrangements of alkyl carbocations, the direction of rearrangement is usually toward the most stable carbocation (or radical), which is tertiary > secondary > primary, but rearrangements in the other direction have also been found,¹⁰² and often the product is a mixture corresponding to an equilibrium mixture of the possible carbocations. In the Wagner–Meerwein rearrangement, the rearrangement has been observed for a secondary to a secondary carbocation rearrangement, leading to some controversy. Winstein¹⁰³ described norbornyl cations in terms of the resonance structures represented by the nonclassical ion **50**.¹⁰⁴ This view was questioned, primarily by Brown,¹⁰⁵ who suggested that the facile rearrangements could be explained by a series of fast 1,3-Wagner–Meerwein shifts.¹⁰⁶

¹⁰⁰For example, see Kleinfelter, D.C.; Schleyer, P.v.R. *J. Am. Chem. Soc.* **1961**, *83*, 2329; Collins, C.J.; Cheema, Z.K.; Werth, R.G.; Benjamin, B.M. *J. Am. Chem. Soc.* **1964**, *86*, 4913; Berson, J.A.; Hammons, J.H.; McRowe, A.W.; Bergman, R.G.; Remanick, A.; Houston, D. *J. Am. Chem. Soc.* **1967**, *89*, 2590.

¹⁰¹For examples of 3,2-endo shifts, see Bushell, A.W.; Wilder, Jr., P. *J. Am. Chem. Soc.* **1967**, *89*, 5721; Wilder, Jr., P.; Hsieh, W. *J. Org. Chem.* **1971**, *36*, 2552.

¹⁰²See, for example, Cooper, C.N.; Jenner, P.J.; Perry, N.B.; Russell-King, J.; Storesund, H.J.; Whiting, M.C. *J. Chem. Soc. Perkin Trans. 2* **1982**, 605.

There is considerable evidence, however, that the norbornyl cation rearranges with σ -participation,¹⁰⁷ and there is strong NMR evidence for the nonclassical ion in super acids at low temperatures.¹⁰⁸

50

As alluded to above, the term "Wagner–Meerwein rearrangement" is not precise. Some use it to refer to all the rearrangements in this section and in **18-2**. Others use it only when an alcohol is converted to a rearranged alkene. Terpene chemists call the migration of a methyl group the *Nametkin rearrangement*. The term *retopinacol rearrangement* is often applied to some or all of these. Fortunately, this disparity in nomenclature does not seem to cause much confusion.

Sometimes several of these rearrangements occur in one molecule, either simultaneously or in rapid succession. A spectacular example is found in the triterpene series. Friedelin is a triterpenoid ketone found in cork. Reduction gives 3 β -friedelanol (**51**). When this compound is treated with acid, 13(18)-oleanene (**52**) is formed.¹⁰⁹ In this case, *seven* 1,2-shifts take place. On removal of H₂O from position 3 to leave a positive

charge, the following shifts occur: hydride from 4 to 3; methyl from 5 to 4; hydride from 10 to 5; methyl from 9 to 10; hydride from 8 to 9; methyl from 14 to 8; and methyl from 13 to 14. This leaves a positive charge at position 13, which is stabilized by loss of the proton at the 18 position to give **52**. All these shifts are stereospecific, the group always migrating on the side of the ring system on which it is located; that is, a group above the "plane" of the ring system (indicated by a solid line in **51**) moves above the plane, and a group below the plane (dashed line) moves

below it. It is probable that the seven shifts are not all concerted, although some of them may be, for intermediate products can be isolated.¹¹⁰ As an illustration of point 2 (p. 1581), it may be mentioned that friedelene, derived from dehydration of **51**, also gives **52** on treatment with acid.¹¹¹

It was mentioned above that even alkanes undergo Wagner–Meerwein rearrangements if treated with Lewis acids and a small amount of initiator. Catalytic asymmetric Wagner–Meerwein shifts have been observed.¹¹² An interesting application of this reaction is the conversion of tricyclic molecules to adamantane and its derivatives.¹¹³ It has been found that *all* tricyclic alkanes containing 10 carbons are converted to adamantane by treatment with a Lewis acid, such as AlCl_3 . If the substrate contains >10 carbons, alkyl-substituted adamantanes are produced. The IUPAC name for these reactions is *Schleyer adamantization*. Two examples are

If 14 or more carbons are present, the product may be diamantane or a substituted diamantane.¹¹⁴ These reactions are successful because of the high thermodynamic stability of adamantane, diamantane, and similar diamond-like molecules. The most stable of a set of C_nH_m isomers (called the *stabilomer*) will be the end product if the reaction reaches equilibrium.¹¹⁵ Best yields are obtained by the use of “sludge” catalysts¹¹⁶ (i.e., a mixture of AlX_3 and *tert*-butyl bromide or *sec*-butyl bromide).¹¹⁷ Though it is certain that these adamantane-forming reactions take place by nucleophilic 1,2-shifts, the exact pathways are not easy to unravel

because of their complexity.¹¹⁸ Treatment of adamantane-2-¹⁴C with AlCl₃ results in total carbon scrambling on a statistical basis.¹¹⁹

As already indicated, the mechanism of the Wagner–Meerwein rearrangement is usually nucleophilic. Free-radical rearrangements are also known (see the mechanism section of this chapter), though virtually only with aryl migration. However, carbanion mechanisms (electrophilic) have also been found.⁹⁴ Thus Ph₃CCH₂Cl treated with sodium gave Ph₂CHCH₂Ph along with unrearranged products.¹²⁰ This is called the *Grovenstein–Zimmerman rearrangement*. The intermediate is Ph₃CCH₂⁻, and the phenyl moves without its electron pair. Only aryl and vinylic,¹²¹ and not alkyl, groups migrate by the electrophilic mechanism (p. \$\$\$) and transition states or intermediates analogous to **41** and **42** are likely.¹²²

OS V, 16, 194; VI, 378, 845.

18-2 The Pinacol Rearrangement

1/0-Hydro,3/hydroxy-(2/ → 3/alkyl)-migro-elimination

When *vic*-diols (glycols) are treated with acids,¹²³ they can be rearranged to give aldehydes or ketones, although elimination without rearrangement can also be accomplished. This reaction is called the *pinacol rearrangement*; the reaction gets its name from a prototype compound pinacol (Me₂COHCOHMe₂), which is rearranged to pinacolone (Me₃CCOCH₃).¹²⁴ In this type of reaction, reduction can compete with rearrangement.¹²⁵ The reaction has been accomplished many times, with alkyl, aryl, hydrogen, and even ethoxycarbonyl (COOEt)¹²⁶ as migrating

groups. In most cases, each carbon has at least one alkyl or aryl group, and the reaction is most often carried out with tri- and tetrasubstituted glycols. As mentioned earlier, glycols in which the four R groups are not identical can give rise to more than one product, depending on which group migrates (see p. 1568 for a discussion of migratory aptitudes). A noncatalytic reaction is possible in supercritical water.¹²⁷

Stereodifferentiation is possible in this reaction.¹²⁸ When TMSOTf was used to initiate the reaction, it was shown to be highly regioselective.¹²⁹ Mixtures are often produced, and which group preferentially migrates may depend on the reaction conditions, as well as on the nature of the substrate. Thus the

action of cold, concentrated sulfuric acid on **53** produces mainly the ketone **54** (methyl migration), while treatment of **53** with acetic acid containing a trace of sulfuric acid gives mostly **55** (phenyl migration).¹³⁰ If at least one R is hydrogen, aldehydes can be produced as well as ketones. Generally, aldehyde formation is favored by the use of mild conditions (lower temperatures, weaker acids), because under more drastic conditions the aldehydes may be converted to ketones (**18-4**). The reaction has been carried out in the solid state, by treating solid substrates with HCl gas or with an organic solid acid.¹³¹

The mechanism involves a simple 1,2-shift. The ion **56** (where all four R groups are Me) has been trapped by the addition of tetrahydrothiophene.¹³² It may seem odd that a migration takes place when the positive charge is already at a tertiary position, but carbocations stabilized by an oxygen atom are even more stable than tertiary alkyl cations (p. 242). There is also the driving force supplied by the fact that the new carbocation can immediately stabilize itself by losing a proton.

It is obvious that other compounds in which a positive charge can be placed on a carbon α to one bearing an OH group can also give this rearrangement. This is true for β -amino alcohols, which rearrange on treatment with nitrous acid (this is called

18-3 Expansion and Contraction of Rings

Demyanov ring contraction; Demyanov ring expansion

When a positive charge is formed on an alicyclic carbon, migration of an alkyl group can take place to give ring contraction, producing a ring that is one carbon smaller than the original, as in the interconversion of the cyclobutyl cation and the

cyclopropylcarbiny l cation.

Note that this change involves conversion of a secondary to a primary carbocation. In a similar manner, when a positive charge is placed on a carbon atom to an alicyclic ring, ring expansion can take place.¹⁵⁹ The new carbocation, and the old one, can then give products by combination with a nucleophile (e.g., the alcohols shown above), or by elimination, so that this reaction is a special case of **18-1**. Often, both rearranged and unrearranged products are formed, so that, for example, cyclobutylamine and cyclopropylmethylamine give similar mixtures of the two alcohols shown above on treatment with nitrous acid (a small amount of 3-buten-1-ol is also produced). When the carbocation is formed by diazotization of an amine, the reaction is called the *Demyanov rearrangement*,¹⁶⁰ but of course similar products are formed when the carbocation is generated in other ways. The expansion reaction has been performed on rings of C₃–C₈,¹⁶¹ but yields are best with the smaller rings, where relief of small-angle strain provides a driving force for the reaction. The contraction reaction has been applied to four-membered rings and to rings of C₆–C₈, but contraction of a cyclopentyl cation to a cyclobutylmethyl system is generally not feasible because of the additional strain involved. Strain is apparently much less of a factor in the cyclobutyl–cyclopropylmethyl interconversion (for a discussion of this interconversion, see p. 450). The influence of substituents on this rearrangement has been examined.¹⁶²

Ring expansions of certain hydroxyamines, such as **58**

¹⁶²Wiberg, K.B.; Shobe, D.; Nelson, G.C. *J. Am. Chem. Soc.* **1993**, *115*, 10645.

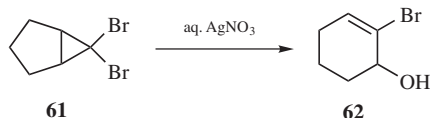

are analogous to the semipinacol rearrangement (**18-2**). This reaction is called the *Tiffeneau–Demyanov ring expansion*. These have been performed on rings of C₄–C₈ and the yields are better than for the simple Demyanov ring expansion. A similar reaction has been used to expand rings of from five to eight members.¹⁶³ In this case, a cyclic bromohydrin of the form **59** is treated with a Grignard reagent which, acting as a base, removes the OH proton to give the alkoxide **60**. Refluxing of **60** brings about the ring enlargement. The reaction has been accomplished for **59** in which at least one R group is phenyl or methyl,¹⁶⁴ but fails when both R groups are hydrogen.¹⁶⁵

A positive charge generated on a three-membered ring gives “contraction” to an allylic cation.¹⁶⁶

We have previously seen (p. 487) that this is the reason nucleophilic substitutions are not feasible at a cyclopropyl substrate. The reaction is often used to convert cyclopropyl halides and tosylates to allylic products, especially for the purpose of ring expansion, an example being the conversion of **61**–**62**.¹⁶⁷ The stereochemistry of these cyclopropyl cleavages is governed by the principle of orbital symmetry conservation (for a discussion, see p. 1644).

Three-membered rings can also be cleaved to unsaturated products in at least two other ways. (1) On pyrolysis, cyclopropanes can undergo “contraction” to

¹⁶³Sisti, A.J. *Tetrahedron Lett.* **1967**, 5327; *J. Org. Chem.* **1968**, *33*, 453. See also, Sisti, A.J.; Vitale, A.C. *J. Org. Chem.* **1972**, *37*, 4090.

¹⁶⁷Skell, P.S.; Sandler, S.R. *J. Am. Chem. Soc.* **1958**, *80*, 2024.

propenes.¹⁶⁸ In the simplest case, cyclopropane gives propene when heated to 400–500°C. The mechanism is generally regarded¹⁶⁹ as involving a diradical

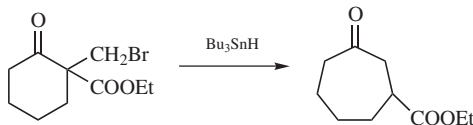

intermediate¹⁷⁰ (recall that free-radical 1,2 migration is possible for diradicals, p. 1574). (2) The generation of a carbene or carbenoid carbon in a three-membered ring can lead to allenes, and allenes are often prepared in this

way.¹⁷¹ Flash vacuum pyrolysis of 1-chlorocyclopropene thermally rearranges to chloroallene.¹⁷² One way to generate, such a species is treatment of a 1,1-dihalo-cyclopropane with an alkyllithium compound (**12-39**).¹⁷³ In contrast, the generation of a carbene or carbenoid at a cyclopropylmethyl carbon gives ring expansion.¹⁷⁴

Some free-radical ring enlargements are also known, an example being:¹⁷⁵

¹⁶⁸For reviews, see Berson, J.A., in de Mayo, P. *Rearrangements in Ground and Excited States*, Vol. 1, Academic Press, NY, **1980**, pp. 324–352; *Ann. Rev. Phys. Chem.* **1977**, 28, 111; Bergman, R.G., in Kochi, J.K. *Free Radicals*, Vol. 1, Wiley, NY, **1973**, pp. 191–237; Frey, H.M. *Adv. Phys. Org. Chem.* **1966**, 4, 147, see pp. 148–170.

¹⁶⁹For evidence that diradical intermediates may not be involved, at least in some cases, see Fields, R.; Haszeldine, R.N.; Peter, D. *Chem. Commun.* **1967**, 1081; Parry, K.A.W.; Robinson, P.J. *Chem. Commun.* **1967**, 1083; Clifford, R.P.; Holbrook, K.A. *J. Chem. Soc. Perkin Trans. 2* **1972**, 1972; Baldwin, J.E.; Grayston, M.W. *J. Am. Chem. Soc.* **1974**, 96, 1629, 1630.

¹⁷⁰We have seen before that such diradicals can close up to give cyclopropanes (**17-34**). Therefore, pyrolysis of cyclopropanes can produce not only propenes, but also isomerized (cis → trans or optically active → inactive) cyclopropanes. See, for example, Berson, J.A.; Balquist, J.M. *J. Am. Chem. Soc.* **1968**, 90, 7343; Bergman, R.G.; Carter, W.L. *J. Am. Chem. Soc.* **1969**, 91, 7411.

¹⁷¹For reviews, see Schuster, H.F.; Coppola, G.M. *Allenes in Organic Synthesis*, Wiley, NY, **1984**, pp. 20–23; Kirmse, W. *Carbene Chemistry*, 2nd ed., Academic Press, NY, **1971**, pp. 462–467.

¹⁷⁵Dowd, P.; Choi, S. *Tetrahedron Lett.* **1991**, 32, 565; *Tetrahedron* **1991**, 47, 4847. For a related ring expansion, see Baldwin, J.E.; Adlington, R.M.; Robertson, J. *J. Chem. Soc., Chem. Commun.* **1988**, 1404.

This reaction has been used to make rings of 6, 7, 8, and 13 members. A possible mechanism is

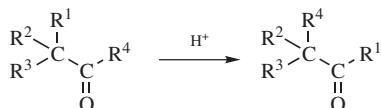

This reaction has been extended to the expansion of rings by three or four carbons, by the use of a substrate containing $(\text{CH}_2)_n\text{X}$ ($n = 3$ or 4) instead of CH_2Br .¹⁷⁶ By this means, 5-, 6-, and 7-membered rings were enlarged to 18–11-membered rings.

18-4 Acid-Catalyzed Rearrangements of Aldehydes and Ketones

1/Alkyl,2/alkyl-interchange, and so on

Rearrangements of this type, where a group α to a carbonyl "changes places" with a group attached to the carbonyl carbon, occur when migratory aptitudes are favorable.¹⁷⁷ The R^2 , R^3 , and R^4 groups may be alkyl or hydrogen. Certain aldehydes have been converted to ketones, and ketones to other ketones (though more drastic conditions are required for the latter), but no rearrangement of a ketone to an aldehyde ($\text{R}^1 = \text{H}$) has so far been reported. There are two mechanisms,¹⁷⁸ each beginning with protonation of the oxygen and each involving two migrations. In one pathway, the migrations are in opposite directions:¹⁷⁹

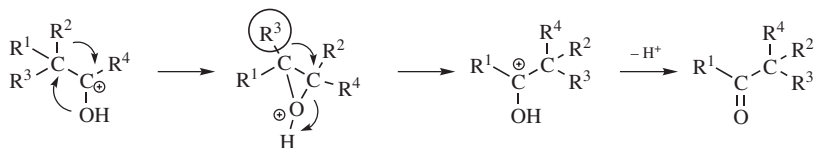

¹⁷⁶Dowd, P.; Choi, S. *J. Am. Chem. Soc.* **1987**, *109*, 6548; *Tetrahedron Lett.* **1991**, 32, 565.

¹⁷⁷For reviews, see Fry, A. *Mech. Mol. Migr.* **1971**, *4*, 113; Collins, C.J.; Eastham, J.F., in Patai, S. *The Chemistry of the Carbonyl Group*, Vol. 1, Wiley, NY, **1966**, pp. 771–790.

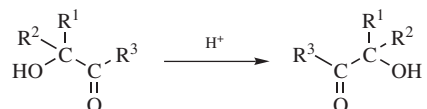

¹⁷⁸Favorskii, A.; Chilingaren, A. *C. R. Acad. Sci.* **1926**, 182, 221.

¹⁷⁹Kendrick Jr., L.W.; Benjamin, B.M.; Collins, C.J. *J. Am. Chem. Soc.* **1958**, *80*, 4057; Rothrock, T.S.; Fry, A. *J. Am. Chem. Soc.* **1958**, *80*, 4349; Collins, C.J.; Bowman, N.S. *J. Am. Chem. Soc.* **1959**, *81*, 3614.

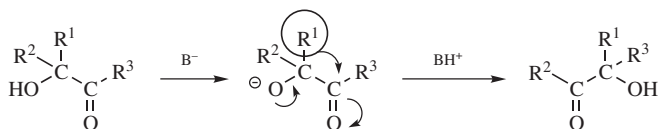

In the other pathway, the migrations are in the same direction. The actual mechanism of this pathway is not certain, but an epoxide (protonated) intermediate¹⁸⁰ is one possibility:¹⁸¹

If the reaction is carried out with ketone labeled in the C=O group with ¹⁴C, the first pathway predicts that the product will contain all the ¹⁴C in the C=O carbon, while in the second pathway the label will be in the α carbon (demonstrating migration of oxygen). The results of such experiments¹⁸² have shown that in some cases only the C=O carbon was labeled, in other cases only the α carbon, while in still others both carbons bore the label, indicating that in these cases both pathways were in operation. With α -hydroxy aldehydes and ketones, the process may stop after only one migration (this is called the α -ketol rearrangement).

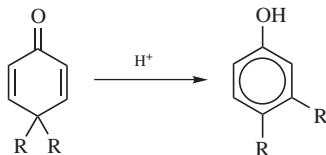

The α -ketol rearrangement can also be brought about by base catalysis, but only if the alcohol is tertiary, since if R¹ or R² = hydrogen, enolization of the substrate is more favored than rearrangement.

18-5 The Dienone-Phenol Rearrangement

2/C \rightarrow 5/O-Hydro,1/C \rightarrow 2/C-alkyl-bis-migration

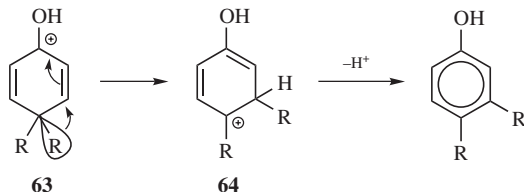

¹⁸⁰Zook, H.D.; Smith, W.E.; Greene, J.L. *J. Am. Chem. Soc.* **1957**, 79, 4436.

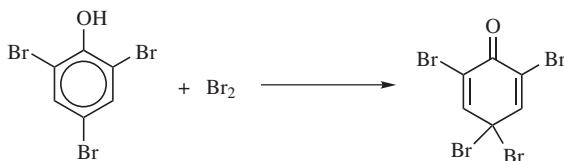

¹⁸¹Some such pathway is necessary to account for the migration of oxygen that is found. It may involve a protonated epoxide, a 1,2-diol, or simply a [1,2]-shift of an OH group.

¹⁸²See, for example, Barton, S.; Porter, C.R. *J. Chem. Soc.* **1956**, 2483; Zalesskaya, T.E.; Remizova, T.B. *J. Gen. Chem. USSR* **1965**, 35, 29; Fry, A.; Oka, M. *J. Am. Chem. Soc.* **1979**, 101, 6353.

Cyclohexadienone derivatives that have two alkyl groups in the 4 position undergo, on acid treatment,¹⁸³ 1,2 migration of one of these groups from **63** to give the phenol. Note that a photochemical version of this reaction has been observed.¹⁸⁴

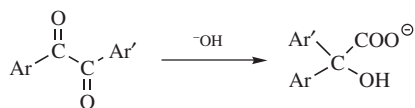

The driving force in the overall reaction (the *dienone-phenol rearrangement*) is of course creation of an aromatic system.¹⁸⁵ Note that **63** and **64** are arenium ions (p. 240), the same as those generated by attack of a phenol on an electrophile.¹⁸⁶ Sometimes, in the reaction of a phenol with an electrophile, a kind of reverse rearrangement (called the *phenol-dienone rearrangement*) takes place, though without an actual migration.¹⁸⁷ An example is

18-6 The Benzil-Benzilic Acid Rearrangement

1/*O*-Hydro,3/oxido-(1/ → 2/aryl)-migr-o-addition

When treated with base, α -diketones rearrange to give the salts of α -hydroxy acids, a reaction known as the *benzil-benzilic acid rearrangement* (benzil is

¹⁸³For a reagent that greatly accelerates this reaction, see Chalais, S.; Laszlo, P.; Mathy, A. *Tetrahedron Lett.* **1986**, 27, 2627.

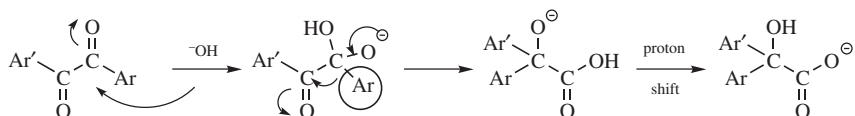

¹⁸⁴Guo, Z.; Schultz, A.G. *Org. Lett.* **2001**, 3, 1177.

¹⁸⁵For reviews, see Perkins, M.J.; Ward, P. *Mech. Mol. Migr.* **1971**, 4, 55, 90–103; Miller, B. *Mech. Mol. Migr.* **1968**, 1, 247; Shine, H.J. *Aromatic Rearrangements*, Elsevier, NY, **1967**, pp. 55–68; Waring, A.J. *Adv. Alicyclic Chem.* **1966**, 1, 129, 207–223. For a review of other rearrangements of cyclohexadienones, see Miller, B. *Acc. Chem. Res.* **1975**, 8, 245.

¹⁸⁶For evidence that these ions are indeed intermediates in this rearrangement, see Vitullo, V.P.; Grossman, N. *J. Am. Chem. Soc.* **1972**, 94, 3844; Planas, A.; Tomás, J.; Bonet, J. *Tetrahedron Lett.* **1987**, 28, 471.

¹⁸⁷For a review, see Ershov, V.V.; Volod'kin, A.A.; Bogdanov, G.N. *Russ. Chem. Rev.* **1963**, 32, 75.

PhCOCOPh; benzilic acid is Ph₂COHCOOH).¹⁸⁸ A rhodium catalyzed version of this reaction has also been reported.¹⁸⁹ Though the reaction is usually illustrated with aryl groups, it can also be applied to aliphatic diketones¹⁹⁰ and to α -keto aldehydes. The use of an alkoxide instead of hydroxide gives the corresponding ester directly,¹⁹¹ though alkoxide ions that are readily oxidized (e.g., OEt⁻ or OCHMe₂⁻) are not useful here, since they reduce the benzil to a benzoin. The mechanism is similar to the rearrangements in **18-1-18-4**, but there is a difference: The migrating group does not move to a carbon with an open sextet. The carbon makes room for the migrating group by releasing a pair of π electrons from the C=O bond to the oxygen. The first step is attack of the base at the carbonyl group, the same as the first step of the tetrahedral mechanism of nucleophilic substitution (p. 1254) and of many additions to the C=O bond (Chapter 16):

The mechanism has been intensely studied,¹⁸⁸ and there is much evidence for it.¹⁹² The reaction is irreversible.

OS I, 89.

18-7 The Favorskii Rearrangement

2/Alkoxy-de-chloro(2) \rightarrow 1/alkyl)-migro-substitution

The reaction of α -halo ketones (chloro, bromo, or iodo) with alkoxide ions¹⁹³ to give rearranged esters is called the *Favorskii rearrangement*.¹⁹⁴ The use of

Chem.* **1996**, *61*, 7611; Hunter, D.H.; Stothers, J.B.; Warnhoff, E.W., in de Mayo, P. *Rearrangements in Ground and Excited States*, Vol. 1, Academic Press, NY, **1980**, pp. 437-461; Chenier, P.J. *J. Chem. Educ.* **1978**, *55*, 286; Rappe, C., in Patai, S. *The Chemistry of the Carbon-Halogen Bond*, pt. 2, Wiley, NY, **1973**, pp. 1084-1101; Redmore, D.; Gutsche, C.D. *Carbocyclic Ring Expansion Reactions*, Academic Press, NY, **1968**, pp. 46-69; Akhrem, A.A.; Ustyuyuk, T.K.; Titov, Yu.A. *Russ. Chem. Rev.* **1970**, *39*, 732. For an asymmetric version, see Satoh, T.; Motohashi, S.; Kimura, S.; Tokutake, N.; Yamakawa, K. *Tetrahedron Lett.* **1993**, *34*, 4823.

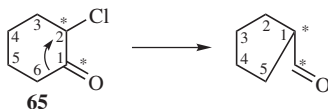

hydroxide ions or amines as bases leads to the free carboxylic acid (salt) or amide, respectively, instead of the ester. Cyclic α -halo ketones give ring contraction, as in the conversion of **65**–**66**.

The reaction has also been carried out on α -hydroxy ketones¹⁹⁵ and on α,β -epoxy ketones, which give β -hydroxy acids.¹⁹⁶ The fact that an epoxide gives a reaction analogous to a halide indicates that the oxygen and halogen are leaving groups in a nucleophilic substitution step.

Through the years, the mechanism¹⁹⁷ of the Favorskii rearrangement has been the subject of much investigation; at least five different mechanisms have been proposed. However, the finding¹⁹⁸ that **67** and **68** both give **69** (this behavior is typical) shows that any mechanism where the halogen leaves and R^1 takes its place is invalid, since in such a case **67** would be expected to give **69** (with PhCH_2 migrating), but **68** should give PhCHMeCOOH (with CH_3 migrating). That is, in the case of **68**, it was PhCH that migrated and not methyl. Another important result was determined by radioactive labeling. **65**, in which C-1 and C-2 were equally labeled with ^{14}C , was converted to **66**. The product was found to contain 50% of the label on the carbonyl carbon, 25% on C-1, and 25% on C-2.¹⁹⁹ Now the carbonyl carbon, which originally carried half of the radioactivity, still had this much, so the rearrangement did not directly affect it. However, if the C-6 carbon had migrated to C-2, the other half of the radioactivity would be only on C-1 of the product:

¹⁹⁵Craig, J.C.; Dinner, A.; Mulligan, P.J. *J. Org. Chem.* **1972**, *37*, 3539.

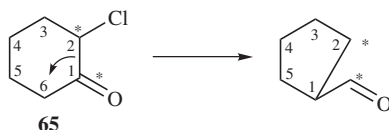

¹⁹⁶See, for example, House, H.O.; Gilmore, W.F. *J. Am. Chem. Soc.* **1961**, *83*, 3972; Mouk, R.W.; Patel, K.M.; Reusch, W. *Tetrahedron* **1975**, *31*, 13.

¹⁹⁷For a review of the mechanism, see Baretta, A.; Waegell, B. *React. Intermed. (Plenum)* **1982**, *2*, 527.

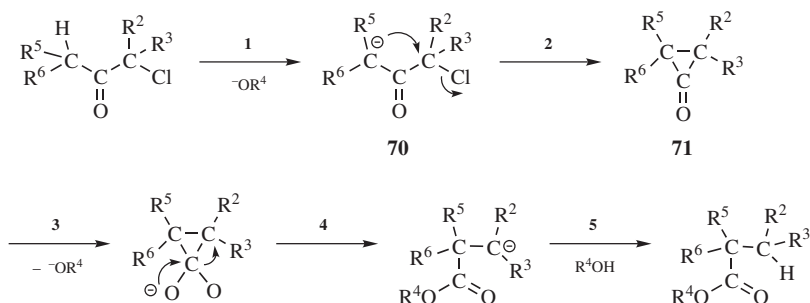

¹⁹⁸McPhee, W.D.; Klingsberg, E. *J. Am. Chem. Soc.* **1944**, *66*, 1132; Bordwell, F.G.; Scamehorn, R.G.; Springer, W.R. *J. Am. Chem. Soc.* **1969**, *91*, 2087.

¹⁹⁹Loftfield, R.B. *J. Am. Chem. Soc.* **1951**, *73*, 4707.

On the other hand, if the migration had gone the other way: If the C-2 carbon had migrated to C-6—then this half of the radioactivity would be found solely on C-2 of the product:

The fact that C-1 and C-2 were found to be equally labeled showed that *both migrations occurred*, with equal probability. Since C-2 and C-6 of **65** are not equivalent, this means that there must be a symmetrical intermediate.²⁰⁰ The type of intermediate that best fits the circumstances is a cyclopropanone,²⁰¹ and the mechanism (for the general case) is formulated (replacing R¹ of our former symbolism with CHR⁵R⁶, since it is obvious that for this mechanism an α hydrogen is required on the non-halogenated side of the carbonyl):

The intermediate corresponding to **71** in the case of **65** is a symmetrical compound, and the three-membered ring can be opened with equal probability on either side of the carbonyl, accounting for the results with ¹⁴C. In the general case, **71** is not symmetrical and should open on the side that gives the more stable carbanion.²⁰² This accounts for the fact that **67** and **68** give the same product. The intermediate in both cases is **70**, which always opens to give the carbanion stabilized by resonance. The cyclopropanone intermediate (**71**) has been isolated in the case where R² = R⁵ = *t*-Bu and R³ = R⁶ = H,²⁰³ and it

²⁰⁰A preliminary migration of the chlorine from C-2 to C-6 was ruled out by the fact that recovered **65** had the same isotopic distribution as the starting **65**.

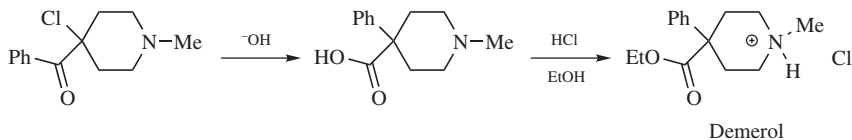

²⁰¹Although cyclopropanones are very reactive compounds, several of them have been isolated. For reviews of cyclopropanone chemistry, see Wasserman, H.H.; Clark, G.M.; Turley, P.C. *Top. Curr. Chem.* **1974**, *47*, 73; Turro, N.J. *Acc. Chem. Res.* **1969**, *2*, 25.

²⁰²Factors other than carbanion stability (including steric factors) may also be important in determining which side of an unsymmetrical **71** is preferentially opened. See, for example, Rappe, C.; Knutsson, L. *Acta Chem. Scand.*, **1967**, *21*, 2205; Rappe, C.; Knutsson, L.; Turro, N.J.; Gagosian, R.B. *J. Am. Chem. Soc.* **1970**, *92*, 2032.

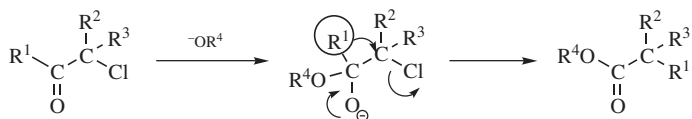

²⁰³Pazos, J.F.; Pacifici, J.G.; Pierson, G.O.; Sclove, D.B.; Greene, F.D. *J. Org. Chem.* **1974**, *39*, 1990.

has also been trapped.²⁰⁴ Also, cyclopropanones synthesized by other methods have been shown to give Favorskii products on treatment with NaOMe or other bases.²⁰⁵

The mechanism discussed is in accord with all the facts when the halo ketone contains an α hydrogen on the other side of the carbonyl group. However, ketones that do not have a hydrogen there also rearrange to give the same type of product. This is usually called the *quasi-Favorskii rearrangement*. An example is found in the preparation of Demerol:²⁰⁶

The quasi-Favorskii rearrangement obviously cannot take place by the cyclopropanone mechanism. The mechanism that is generally accepted (called the *semi-benzilic mechanism*²⁰⁷) is a base-catalyzed pinacol

rearrangement-type mechanism similar to that of **18-6**. This mechanism requires inversion at the migration terminus and this has been found.²⁰⁸ It has been shown that even where there is an appropriately situated a hydrogen, the semibenzilic mechanism may still operate.²⁰⁹

An interesting analog of the Favorskii rearrangement treats a ketone, such as 4-*tert*-butylcyclohexanone, without an α -halogen with $\text{Ti}(\text{NO}_3)_3$ to give 3-*tert*-butylcyclopentane-1-carboxylic acid.²¹⁰

18-8 The Arndt–Eistert Synthesis

In the *Arndt–Eistert synthesis*, an acyl halide is converted to a carboxylic acid with one additional carbon.²¹¹ The first step of this process is reaction **16-89**. The actual rearrangement occurs in the second step on treatment of the diazo ketone with water and silver oxide or with silver benzoate and triethylamine. This rearrangement is called the *Wolff rearrangement*.²¹² It is the best method of increasing a carbon chain by one if a *carboxylic acid* is available (**10-75** and **16-30** begin with alkyl halides). If an alcohol R'OH is used instead of water, the ester RCH₂COOR' is isolated directly.²¹³ Similarly, ammonia gives the amide. Other catalysts are sometimes used (e.g., colloidal platinum, copper, etc.), but occasionally the diazo ketone is simply heated or photolyzed in the presence of water, an alcohol, or ammonia, with no catalyst at all.²¹⁴ The photolysis method²¹⁵ often gives better results than the silver catalysis method. Of course, diazo ketones prepared in any other way also give the rearrangement.²¹⁶ The reaction is of wide scope. The R group may be alkyl or aryl and may contain many functional groups including unsaturation, but not including groups acidic enough to react with CH₂N₂ or diazo ketones (e.g., **10-5** and **10-19**). Sometimes the reaction is performed with other diazoalkanes (i.e., R'CHN₂) to give RCHR'COOH. The reaction has often been used for ring contraction of cyclic diazo ketones,²¹⁷ such as **72**.²¹⁸

The mechanism is generally regarded as involving formation of a carbene.²¹⁹ It is the divalent carbon that has the open sextet and to which the migrating group brings its electron pair:

The actual product of the reaction is thus the ketene, which then reacts with water (**15-3**), an alcohol (**15-5**), or ammonia or an amine (**15-8**). Particularly stable ketenes²²⁰ (e.g., Ph₂C=C=O) have been isolated and others have been trapped in other ways (e.g., as β -lactams,²²¹ **16-96**). The purpose of the catalyst is not well understood, though many suggestions have been made. This mechanism is strictly analogous to that of the Curtius rearrangement (**18-14**). Although the mechanism as shown above involves a free carbene and there is much evidence to support this,²²² it is also possible that at least in some cases the two steps are concerted and a free carbene is absent.

When the Wolff rearrangement is carried out photochemically, the mechanism is basically the same,²¹⁵ but another pathway can intervene. Some of the ketocarbene originally formed can undergo a carbene-carbene rearrangement, through an oxirene intermediate.²²³ This was shown by ¹⁴C labeling experiments, where

diazo ketones labeled in the carbonyl group gave rise to ketenes that bore the label at both C=C carbons.²²⁴ In general, the smallest degree of scrambling (and thus of

the oxirene pathway) was found when $R' = H$. An intermediate believed to be an oxirene has been detected by laser spectroscopy.²²⁵ The oxirene pathway is not found in the thermal Wolff rearrangement. It is likely that an excited singlet state of the carbene is necessary for the oxirene pathway to intervene.²²⁶ In the photochemical process, ketocarbene intermediates, in the triplet state, have been isolated in an Ar matrix at 10–15 K, where they have been identified by UV–visible, IR, and esr spectra.²²⁷ These intermediates went on to give the rearrangement via the normal pathway, with no evidence for oxirene intermediates.

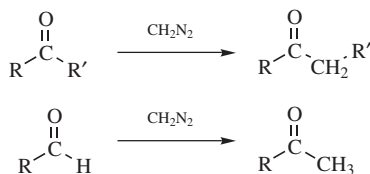

The diazo ketone can exist in two conformations, called $s\text{-(E)}$ and $s\text{-(Z)}$. Studies have shown that Wolff rearrangement takes place preferentially from the $s\text{-(Z)}$ conformation.²²⁸

formation of an epoxide (**16-46**) is a side reaction. Although this reaction appears superficially to be similar to the insertion of carbenes into C–H bonds, **12-21** (and IUPAC names it as an insertion), the mechanism is quite different. This is a true rearrangement and no free carbene is involved. The first step is an addition to the C=O bond:

The betaine **73** can sometimes be isolated. As shown in **16-46**, intermediate **73** can also go to the epoxide. The evidence for this mechanism is summarized in the review by Gutsche.²³⁰ Note that this mechanism is essentially the same as in the apparent “insertions” of oxygen (**18-19**) and nitrogen (**18-16**) into ketones.

Aldehydes give fairly good yields of methyl ketones; that is, hydrogen migrates in preference to alkyl. The most abundant side product is not the homologous aldehyde, but the epoxide. However, the yield of aldehyde at the expense of methyl ketone can be increased by the addition of methanol. If the aldehyde contains electron-withdrawing groups, the yield of epoxides is increased and the ketone is formed in smaller amounts, if at all. Ketones give poorer yields of homologous ketones. Epoxides are usually the predominant product here, especially when one or both R groups contain an electron-withdrawing group. The yield of ketones also decreases with increasing length of the chain. The use of a Lewis acid increases the yield of ketone.²³⁴ Cyclic ketones,²³⁵ three-membered²³⁶ and larger, behave particularly well and give good yields of ketones with the ring expanded by one.²³⁷ Aliphatic diazo compounds (RCHN₂ and R₂CN₂) are sometimes used instead of diazomethane, with the expected results.²³⁸ Ethyl diazoacetate can be used analogously, in the presence of a Lewis acid or of triethyloxonium fluoroborate,²³⁹ to

²³⁸For example, see Smith, R.F. *J. Org. Chem.* **1960**, 25, 453; Warner, C.R.; Walsh, Jr., E.J.; Smith, R.F. *J. Chem. Soc.* **1962**, 1232; Loeschorn, C.A.; Nakajima, M.; Anselme, J. *Bull. Soc. Chim. Belg.* **1981**, 90, 985.

²³⁹Mock, W.L.; Hartman, M.E. *J. Org. Chem.* **1977**, 42, 459, 466; Baldwin, S.W.; Landmesser, N.G. *Synth. Commun.* **1978**, 8, 413.

give a β -keto ester, such as **74**.

When unsymmetrical ketones were used in this reaction (with BF_3 as catalyst), the less highly substituted carbon preferentially migrated.²⁴⁰ The reaction can be made regioselective by applying this method to the α -halo ketone, in which case only the other carbon migrates.²⁴¹ The ethyl diazoacetate procedure has also been applied to the acetals or ketals of α,β -unsaturated aldehydes and ketones.²⁴²

Bicyclic ketones can be expanded to form monocyclic ketones in the presence of certain reagents. Treatment of a bicyclo[4.1.0]hexan-4-one derivative with SmI_2 led to a cyclohexanone.²⁴³ The SmI_2 also converts α -halomethyl cyclic ketones to the next larger ring ketone²⁴⁴ and cyclic ketones to the next larger ring ketone in the presence of CH_2I_2 .²⁴⁵ α -Chloro- α -3-iodopropylcyclobutanones were converted to cycloheptanones using radical conditions ($\text{Bu}_3\text{SnH/AIBN}$).²⁴⁶

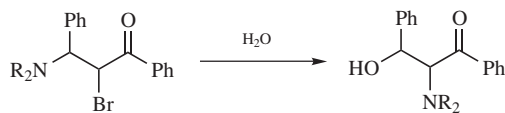

Another homologation reaction converts an aldehyde to its tosyl hydrazone, and subsequent reaction with an aldehyde and NaOEt/EtOH give a ketone.²⁴⁷ The reaction of an aldehyde with vinyl acetate and barium hydroxide gives the homologated conjugated aldehyde.²⁴⁸

that is opened on the opposite side, resulting in migration of the neighboring group. In the example shown above ($\text{NR}_2 = \text{morpholino}$),²⁴⁹ the reaction took place via an aziridinium salt **75** to give an α -amino- β -hydroxy ketone.

Sulfonate esters and halides can also migrate in this reaction.²⁵⁰ α -Halo and α -acyloxy epoxides undergo ready rearrangement to α -halo and α -acyloxy ketones, respectively.²⁵¹ These substrates are very prone to rearrange, and often do so on standing without a catalyst, though in some cases an acid catalyst is necessary. The reaction is essentially the same as the rearrangement of epoxides shown in **18-2**, except that in this case halogen or acyloxy is the migrating group (as shown above; however, it is also possible for one of the R groups (alkyl, aryl, or hydrogen) to migrate instead, and mixtures are sometimes obtained).

18-11 Migration of Boron

Hydro,dialkylboro-interchange, and so on

Boranes are prepared by the reaction of $\text{BH}_3(\text{B}_2\text{H}_6)$ or an alkylborane with an alkene (**15-16**). When a nonterminal borane is heated at temperatures ranging from 100 to 200°C, the boron moves toward the end of the chain.²⁵² The reaction is catalyzed by small amounts of borane or other species containing B-H bonds.

The boron can move past a branch, for example,

but not past a double branch, for example,

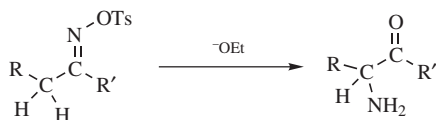

The reaction is an equilibrium: **76**, **77**, and **78** each gave a mixture containing ~40% **76**, 1% **77**, and 59% **78**. The migration can go quite a long distance. Thus $(C_{11}H_{23}CHC_{11}H_{23})_3B$ was completely converted to $(C_{23}H_{47})_3B$, involving a migration of 11 positions.²⁵³ If the boron is on a cycloalkyl ring, it can move around

the ring; if any alkyl chain is also on the ring, the boron may move from the ring to the chain, ending up at the end of the chain.²⁵⁴ The reaction is useful for the migration of double bonds in a controlled way (see **12-2**). The mechanism may involve a π complex, at least partially.²⁵⁵

18-12 The Neber Rearrangement

Neber oxime tosylate-amino ketone rearrangement

α -Amino ketones can be prepared by treatment of ketoxime tosylates with a base, such as ethoxide ion or pyridine.²⁵⁶ This reaction is called the *Neber rearrangement*. The R group is usually aryl, though the reaction has been carried out with

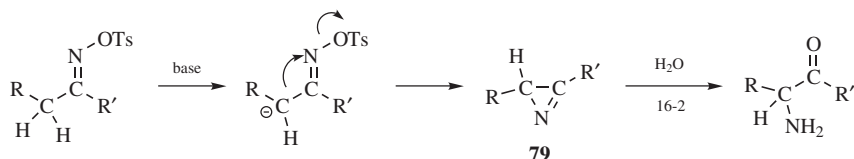

²⁵³Logan, T.J. *J. Org. Chem.* **1961**, *26*, 3657.

²⁵⁴Brown, H.C.; Zweifel, G. *J. Am. Chem. Soc.* **1967**, *89*, 561.

²⁵⁵See Wood, S.E.; Rickborn, B. *J. Org. Chem.* **1983**, *48*, 555; Field, L.D.; Gallagher, S.P. *Tetrahedron Lett.* **1985**, *26*, 6125.

²⁵⁶For a review, see Conley, R.T.; Ghosh, S. *Mech. Mol. Migr.* **1971**, *4*, 197, pp. 289–304.

R = alkyl or hydrogen. The R' group may be alkyl, or aryl but not hydrogen. The Beckmann rearrangement (**18-17**) and the abnormal Beckmann reaction (elimination to the nitrile, **17-30**) may be side reactions, although these generally occur in acid media. A similar rearrangement is given by *N,N*-dichloroamines of the type RCH₂CH(NCl₂)R', where the product is also RCH(NH₂)COR'.²⁵⁷ The mechanism of the Neber rearrangement is via an azirine intermediate **79**.²⁵⁸

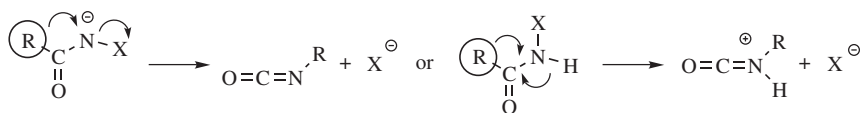

The best evidence for this mechanism is that the azirine intermediate has been isolated.^{258,259} In contrast to the Beckmann rearrangement, this one is sterically indiscriminate.²⁶⁰ Both a syn and an anti ketoxime give the same product. The mechanism as shown above consists of three steps. However, it is possible that the first two steps are concerted, and it is also possible that what is shown as the second step is actually two steps: loss of OTs to give a nitrene, and formation of the azirine. In the case of the dichloroamines, HCl is first lost to give RCH₂C(=NCl)R', which then behaves analogously.²⁶¹ *N*-Chloroimines prepared in other ways also give the reaction.²⁶²

OS V, 909; VII, 149.

C. Carbon-to-Nitrogen Migrations of R and AR

The reactions in this group are nucleophilic migrations from a carbon to a nitrogen atom. In each case the nitrogen atom either has six electrons in its outer shell (and thus invites the migration of a group carrying an electron pair) or else loses a nucleofuge concurrently with the migration (p. 1560). Reactions **18-13-18-16** are used to prepare amines from acid derivatives. Reactions **18-16** and **18-17** are used to prepare amines from ketones. The mechanisms of **18-13-18-16** (with carboxylic acids) are very similar and follow one of two patterns:

²⁵⁷Baumgarten, H.E.; Petersen, H.E. *J. Am. Chem. Soc.* **1960**, 82, 459, and references cited therein.

²⁵⁸Cram, D.J.; Hatch, M.J. *J. Am. Chem. Soc.* **1953**, 75, 33; Hatch, M.J.; Cram, D.J. *J. Am. Chem. Soc.* **1953**, 75, 38.

²⁵⁹Neber, P.W.; Burgard, A. *Liebigs Ann. Chem.* **1932**, 493, 281; Parcell, R.F. *Chem. Ind. (London)* **1963**, 1396.

²⁶⁰House, H.O.; Berkowitz, W.F. *J. Org. Chem.* **1963**, 28, 2271.

²⁶¹For example, see Nakai, M.; Furukawa, N.; Oae, S. *Bull. Chem. Soc. Jpn.* **1969**, 42, 2917.

²⁶²Baumgarten, H.E.; Petersen, J.M.; Wolf, D.C. *J. Org. Chem.* **1963**, 28, 2369.

Some of the evidence²⁶³ is (1) configuration is retained in R (p. 1563); (2) the kinetics are first order; (3) intramolecular rearrangement is shown by labeling; and (4) no rearrangement occurs *within* the migrating group, for example, a neopentyl group on the carbon of the starting material is still a neopentyl group on the nitrogen of the product.

In many cases, it is not certain whether the nucleofuge X is lost first, creating an intermediate nitrene²⁶⁴ or nitrenium ion, or whether migration and loss of the nucleofuge are simultaneous, as shown above.²⁶⁵ It is likely that both possibilities can exist, depending on the substrate and reaction conditions.

18-13 The Hofmann Rearrangement

Bis(hydrogen)-(2/ 1/*N*-alkyl)-migr-detachment (formation of isocyanate)

In the *Hofmann rearrangement*, an unsubstituted amide is treated with sodium hypobromite (or sodium hydroxide and bromine, which is essentially the same thing) to give a primary amine that has one carbon fewer than the starting amide.²⁶⁶ The actual product is the isocyanate, but this compound is seldom isolated²⁶⁷ since it is usually hydrolyzed under the reaction conditions. The R group may be alkyl or aryl, but if it is an alkyl group of more than about six or seven carbons, low yields are obtained unless Br₂ and NaOMe are used instead of Br₂ and NaOH.²⁶⁸ Another modification uses NBS/NaOMe.²⁶⁹ Under these conditions the product of addition to the isocyanate is the carbamate RNHCOOMe (**16-8**), which is easily isolated or can be hydrolyzed to the amine. Side reactions when NaOH is the base are formation of ureas RNHCONHR and acylureas RCONHCONHR by addition, respectively, of RNH₂ and RCONH₂ to RNCO (**16-20**). If acylureas are desired, they can be made the main products by using only one-half of the usual quantities of Br₂ and NaOH. Another side product, but only from primary R, is the nitrile derived from oxidation of RNH₂ (**19-5**). Imides react to give amino acids, for example, phthalimide gives *o*-aminobenzoic acid. α -Hydroxy and α -halo amides give aldehydes and ketones by way of the unstable α -hydroxy- or α -haloamines. However, a side product with an α -halo amide is a *gem*-dihalide. Ureas analogously give hydrazines.

²⁶³For a discussion of this mechanism and the evidence for it, see Smith, P.A.S., in de Mayo, P. *Molecular Rearrangements*, Vol. 1, Wiley, NY, **1963**, Vol. 1, pp. 258–550.

²⁶⁴For a review of rearrangements involving nitrene intermediates, see Boyer, J.H. *Mech. Mol. Migr.* **1969**, 2, 267. See also, Ref. 282.

²⁶⁵The question is discussed by Lwowski, W., in Lwowski *Nitrenes*, Wiley, NY, **1970**, pp. 217–221.

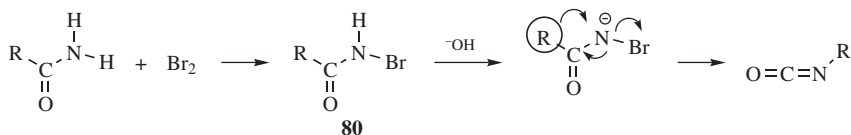

²⁶⁶For a review, see Wallis, E.S.; Lane, J.F. *Org. React.* **1946**, 3, 267.

²⁶⁷If desired, the isocyanate can be isolated by the use of phase-transfer conditions: see Sy, A.O.; Raksis, J.W. *Tetrahedron Lett.* **1980**, 21, 2223.

²⁶⁸For an example of the use of this method at low temperatures, see Radlick, P.; Brown, L.R. *Synthesis* **1974**, 290.

²⁶⁹Huang, X.; Keillor, J.W. *Tetrahedron Lett.* **1997**, 38, 313.

The mechanism follows the pattern outlined on p. 1606.

The first step is an example of **12-52** and intermediate *N*-halo amides (**80**) have been isolated. In the second step, **80** lose a proton to the base. Compound **80** is acidic because of the presence of two electron-withdrawing groups (acyl and halo) on the nitrogen. It is possible that the third step is actually two steps: loss of bromide to form a nitrene, followed by the actual migration, but most of the available evidence favors the concerted reaction.²⁷⁰ A similar reaction can be effected by the treatment of amides with lead tetraacetate.²⁷¹ Among other reagents that convert RCONH₂ to RNH₂ (R = alkyl, but not aryl) are phenyliodosyl bis(trifluoroacetate) PhI(OCOCF₃)₂²⁷² and hydroxy(tosyloxy)iodobenzene PhI(OH)OTs.²⁷³ A mixture of NBS, Hg(OAc)₂, and R'OH is one of several reagent mixtures that convert an amide RCONH₂ to the carbamate RNHCOOR' (R = primary, secondary, or tertiary alkyl or aryl) in high yield.²⁷⁴ A mixture of NBS and DBU (p. 1132) in methanol gives the carbamate,²⁷⁵ as does electrolysis in methanol.²⁷⁶

A variation of the Hofmann rearrangement treated a β-hydroxy primary amide with PhI(O₂CCF₃)₂ in aqueous acetonitrile, giving an isocyanate via -CON-I, which reacts with the hydroxyl group intramolecularly to give a cyclic carbamate.²⁷⁷ Note that carbamates are converted to isocyanates by heating with Montmorillonite K10.²⁷⁸

The *Curtius rearrangement* involves the pyrolysis of acyl azides to yield isocyanates.²⁷⁹ The reaction gives good yields of isocyanates, since no water is present to hydrolyze them to the amine. Of course, they can be subsequently hydrolyzed, and indeed the reaction *can* be carried out in water or alcohol, in which case the products are amines, carbamates, or acylureas, as in **18-13**.²⁸⁰ This is a very general reaction and can be applied to almost any carboxylic acid: aliphatic, aromatic, alicyclic, heterocyclic, unsaturated, and containing many functional groups. Acyl azides can be prepared as in **10-43** or by treatment of acylhydrazines (hydrazides) with nitrous acid (analogous to **12-49**). The Curtius rearrangement is catalyzed by Lewis or protic acids, but these are usually not necessary for good results.

The mechanism is similar to that in **18-13** to give an isocyanate. Also note the exact analogy between this reaction and **18-8**. However, in this case, there is no evidence for a free nitrene and it is probable that the steps are concerted.²⁸¹

Alkyl azides can be similarly pyrolyzed to give imines, in an analogous reaction:²⁸²

The R groups may be alkyl, aryl, or hydrogen, though if hydrogen migrates, the product is the unstable $\text{R}_2\text{C}=\text{NH}$. The mechanism is essentially the same as that of the Curtius rearrangement. However, in pyrolysis of tertiary alkyl azides, there is evidence that free alkyl nitrenes are intermediates.²⁸³ The reaction can also be carried out with acid catalysis, in which case lower temperatures can be used, though the acid may hydrolyze the imine (**16-2**). Cycloalkyl azides give

18-16 The Schmidt Reaction

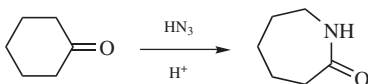

There are actually three reactions called by the name *Schmidt reaction*, involving the addition of hydrazoic acid to carboxylic acids, aldehydes and ketones, and alcohols and alkenes.²⁹⁰ The most common is the reaction with carboxylic acids, illustrated above.²⁹¹ Sulfuric acid is the most common catalyst, but Lewis acids have also been used. Good results are obtained for aliphatic R, especially for long chains. When R is aryl, the yields are variable, being best for sterically hindered compounds like mesitoic acid. This method has the advantage over **18-13** and **18-14** in that there is just one laboratory step from the acid to the amine, but conditions are more drastic.²⁹² Under the acid conditions employed, the isocyanate is virtually never isolated.

The reaction between a ketone and hydrazoic acid is a method for “insertion” of NH between the carbonyl group and one R group, converting a ketone into an amide.²⁹³

Either or both of the R groups may be aryl. In general, dialkyl ketones and cyclic ketones react more rapidly than alkyl aryl ketones, and these more rapidly than diaryl ketones. The latter require sulfuric acid and do not react in concentrated HCl, which is strong enough for dialkyl ketones. Dialkyl and cyclic ketones react sufficiently faster than diaryl or aryl alkyl ketones or carboxylic acids or alcohols so that these functions may be present in the same molecule without interference. Cyclic ketones give lactams:²⁹⁴

²⁹³For reviews, see Koldobskii, G.I.; Tereschenko, G.F.; Gerasimova, E.S.; Bagal, L.I. *Russ. Chem. Rev.* **1971**, *40*, 835; Beckwith, A.L.J., in Zabicky, J. *The Chemistry of Amides*, Wiley, NY, **1970**, pp. 137–145.

²⁹⁴For a review with respect to bicyclic ketones, see Krow, G.R. *Tetrahedron* **1981**, *37*, 1283.

With alkyl aryl ketones, it is the aryl group that generally migrates to the nitrogen, except when the alkyl group is bulky.²⁹⁵ The reaction has been applied to a few aldehydes, but rarely. With aldehydes the product is usually the nitrile (**16-16**). Even with ketones, conversion to the nitrile is often a side reaction, especially with the type of ketone that gives **17-30**. A useful variation of the Schmidt reaction treats a cyclic ketone with an alkyl azide (RN₃)²⁹⁶ in the presence of TiCl₄, generating a lactam.²⁹⁷ An intramolecular Schmidt reaction gives bicyclic amines by treatment of a cyclic alkene having a pendant azidoalkyl group with Hg(ClO₄)₂, and then NaBH₄.²⁹⁸ Another variation treats a silyl enol ether of a cyclic ketone with TMSN₃ and photolyzes the product with UV light to give a lactam.²⁹⁹ α Azido cyclic ketones rearrangement to lactams under radical conditions (Bu₃SnH/AIBN).³⁰⁰

Alcohols and alkenes react with HN₃ to give alkyl azides,³⁰¹ which in the course of reaction rearrange in the same way as discussed in reaction **18-14**.²⁸² The Mitsunobu reaction (**10-17**) can be used to convert alcohols to alkyl azides, and an alternative reagent for azides, (PhO)₂PON₃, for use in the Mitsunobu is now available.³⁰²

There is evidence that the mechanism with carboxylic acids²⁹³ is similar to that of **18-14**, except that it is the protonated azide that undergoes the rearrangement:³⁰³

The first step is the same as that of the A_{AC}1 mechanism (**16-59**) which explains why good results are obtained with hindered substrates. The mechanism with ketones

²⁹⁵Exceptions to this statement have been noted in the case of cyclic aromatic ketones bearing electron-donating groups in ortho and para positions: Bhalerao, U.T.; Thyagarajan, G. *Can. J. Chem.* **1968**, *46*, 3367; Tomita, M.; Minami, S.; Uyeo, S. *J. Chem. Soc. C* **1969**, 183.

HCl–HOAc–Ac₂O, POCl₃,³¹² BiCl₃,³¹³ neat with FeCl₃,³¹⁴ and polyphosphoric acid.³¹⁵ The reaction has been done in supercritical water³¹⁶ and in ionic liquids.³¹⁷ A polymer-bound Beckman rearrangement has been reported.³¹⁸ Simply heating the oxime of benzophenone neat leads to *N*-phenyl benzamide.³¹⁹ The oximes of cyclic ketones give ring enlargement and form the lactam,³²⁰ as in the formation of caprolactam (**83**) from the oxime of cyclohexanone. Heating an oxime of a cyclic ketone, *neat*, with AlCl₃ also leads to the lactam,³²¹ as does microwave irradiation of an oxime on Montmorillonite K10 clay.³²² Other solvent-free reactions are known.³²³ Treatment of a cyclic ketone with NH₂OSO₃H on silica gel followed by microwave irradiation also gives the lactam.³²⁴ Cyclic ketones can be converted directly to lactams in one laboratory step by treatment with NH₂OSO₂OH and formic acid (**16-14** takes place first, then the Beckmann rearrangement).³²⁵ Heating a ketone with hydroxylamine HCl and oxalic acid also gives the amide.³²⁶ Note that the reaction of an imine with BF₃•OEt₂ and *m*-chloroperoxybenzoic acid leads to a formamide.³²⁷

Of the groups attached to the carbon of the C=N unit, the one that migrates in the Beckman rearrangement is generally the one anti to the hydroxyl, and this is

often used as a method of determining the configuration of the oxime. However, it is not unequivocal. It is known that with some oximes the syn group migrates and that with others, especially where R and R' are both alkyl, mixtures of the two possible amides are obtained. However, this behavior does not necessarily mean that the syn group actually undergoes migration. In most cases, the oxime undergoes isomerization under the reaction conditions *before* migration takes place.³²⁸ The scope of the reaction is quite broad and R and R' may be alkyl, aryl, or hydrogen. However, hydrogen very seldom *migrates*, so the reaction is not generally a means of converting aldoximes to unsubstituted amides (RCONH₂). This latter conversion can be accomplished, however, by treatment of the aldoxime with nickel acetate under neutral conditions³²⁹ or by heating the aldoxime for 60 h at 100°C after it has been adsorbed onto silica gel.³³⁰ As in the case of the Schmidt rearrangement, when the oxime is derived from an alkyl aryl ketone, it is generally the aryl group that preferentially migrates.³³¹

Not only do oximes undergo the Beckmann rearrangement, but so also do esters of oximes with many acids, organic and inorganic. A side reaction with many substrates is the formation of nitriles (the "abnormal" Beckmann rearrangement, **17-30**). The other reagents convert OH to an ester leaving group (e.g., OPCL₄ from PCl₅ and OSO₂OH from concentrated H₂SO₄³³²). The *O*-carbonates of imines, such as Ph₂C=N-OCO₂Et, react with BF₃•OEt₂ to give the corresponding amide, in this case *N*-phenyl benzamide.³³³

In the first step of the mechanism, the OH group is converted by the reagent to a better leaving group, for example, proton acids convert it to OH₂⁺. After that, the mechanism³³⁴ follows a course analogous to that for the Schmidt reaction of ketones (**18-16**) from the formation of nitrilium ion **82** on:³³⁵ Alternatively, the attack on **82** can be by the leaving group, if different from H₂O. For example, when PCl₅ is used to induce the reaction, a N-O-PCl₄ species is formed, which generates **82**. Intermediates of the form **82** have been detected by nmr and uv spectroscopy.³³⁶ The rearrangement has also been found to take place by a different mechanism, involving formation of a nitrile by fragmentation, and then addition by

³²⁸Lansbury, P.T.; Mancuso, N.R. *Tetrahedron Lett.* **1965**, 2445 have shown that some Beckmann rearrangements are *authentically* nonstereospecific.

a Ritter reaction (16-91).³³⁷ Beckmann rearrangements have also been carried out photochemically.³³⁸

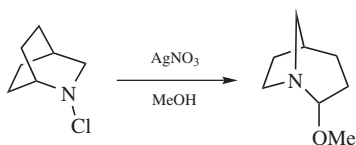

If the rearrangement of oxime sulfonates is induced by organoaluminum reagents,³³⁹ the nitrilium ion intermediate **82** is captured by the nucleophile originally attached to the Al. By this means an oxime can be converted to an imine, an imino thioether (R-N=C-SR), or an imino nitrile (R-N=C-CN).³⁴⁰ In the last case, the nucleophile comes from added trimethylsilyl cyanide. The imine-producing reaction can also be accomplished with a Grignard reagent in benzene or toluene.³⁴¹

In a related reaction, treatment of spirocyclic oxaziridines with MnCl(TPP)³⁴² or photolysis³⁴³ leads to a lactam.

OS II, 76, 371; VIII, 568.

18-18 Stieglitz and Related Rearrangements

Methoxy-de-N-chloro-(2/ → 1/N-alkyl)-migro-substitution, and so on

Besides the reactions discussed at **18-13–18-17**, a number of other rearrangements are known in which an alkyl group migrates from C to N. Certain bicyclic *N*-haloamines, for example *N*-chloro-2-azabicyclo[2.2.2]octane (above), undergo

rearrangement when solvolyzed in the presence of silver nitrate.³⁴⁴ This reaction is similar to the Wagner–Meerwein rearrangement (**18-1**) and is initiated by the silver-catalyzed departure of the chloride ion.³⁴⁵ Similar reactions have been used for ring expansions and contractions, analogous to those discussed for reaction **18-3**.³⁴⁶ An example is the conversion of 1-(*N*-chloroamino)cyclopropanols to β -lactams.³⁴⁷ Methyl prolinolate was converted to the lactam 2-piperidone upon treatment with SmI_2 and pivalic acid–THF.³⁴⁸

The name *Stieglitz rearrangement* is generally applied to the rearrangements of trityl *N*-haloamines and

hydroxylamines. These reactions are similar to the rearrangements of alkyl azides (**18-14**), and the name Stieglitz rearrangement is also given to the rearrangement of trityl azides. Another similar reaction is the rearrangement undergone by tritylamines when treated with lead tetraacetate:³⁴⁹

The treatment of ketones with peroxyacids, such as peroxybenzoic or peroxyacetic acid, or with other peroxy compounds in the presence of acid catalysts, gives carboxylic esters by “insertion” of oxygen³⁵¹ and the carboxylic acid parent of the peroxyacid as a by-product. The reaction is called the *Baeyer–Villiger rearrangement*.³⁵² A particularly good reagent is peroxytrifluoroacetic acid. Reactions with this reagent are rapid and clean, giving high yields of product, though it is often necessary to add a buffer, such as Na₂HPO₄, to prevent transesterification of the product with trifluoroacetic acid that is also formed during the reaction. The reaction is often applied to cyclic ketones to give lactones.³⁵³ Hydrogen peroxide has been used to convert cyclic ketones to lactones using a catalytic amount of MeReO₃³⁵⁴ or a diselenide catalyst.³⁵⁵ Hydrogen peroxide and a MeReO₃ catalyst has been used in an ionic liquid.³⁵⁶ Transition-metal catalysts have been used with peroxyacids to facilitate the oxidation.³⁵⁷ Hydrogen peroxide and PhAsO₃H₂ in hexafluoro-1-propanol can be used.³⁵⁸ Polymer-supported peroxy acids have been used,³⁵⁹ and solvent-free Bayer–Villiger reactions are known.³⁶⁰ Enantioselective synthesis³⁶¹ of chiral lactones from achiral ketones has been achieved by the use of enzymes³⁶²

and other asymmetric reactions are known.³⁶³ Oxidation of chiral substrates with *m*-chloroperoxybenzoic acid (mcpba) also leads to chiral lactones.³⁶⁴

For acyclic compounds, R' must usually be secondary, tertiary, or vinylic, although primary R' has been rearranged with peroxytrifluoroacetic acid,³⁶⁵ with BF₃-H₂O₂,³⁶⁶ and with K₂S₂O₈-H₂SO₄.³⁶⁷ For unsymmetrical ketones the approximate order of migration is tertiary alkyl > secondary alkyl, aryl > primary alkyl > methyl. Since the methyl group has a low migrating ability, the reaction provides a means of cleaving a methyl ketone R'COMe to produce an alcohol or phenol (R'OH) (by hydrolysis of the ester R'OCOMe). The migrating ability of aryl groups is increased by electron-donating and decreased by electron-withdrawing substituents.³⁶⁸ There is a preference of anti over gauche migration.³⁶⁹ Enolizable β-diketones do not react. α-Diketones can be converted to anhydrides.³⁷⁰ With aldehydes, migration of hydrogen gives the carboxylic acid, and this is a way of accomplishing **19-23**. Migration of the other group would give formates, but this seldom happens, though aryl aldehydes have been converted to formates with H₂O₂ and a selenium compound³⁷¹ (see also the Dakin reaction in **19-11**).

The mechanism³⁷² is similar to those of the analogous reactions with hydrazoic acid (**18-16** with ketones) and diazomethane (**18-8**):

One important piece of evidence for this mechanism was that benzophenone-¹⁸O gave ester entirely labeled in the carbonyl oxygen, with none in the alkoxy oxygen.³⁷³ Carbon-14 isotope-effect studies on acetophenones have shown that

migration of aryl groups takes place in the rate-determining step,³⁷⁴ demonstrating that migration of Ar is concerted with departure of OCOR².³⁷⁵ It is hardly likely that migration would be the slow step if the leaving group departed first to give an ion with a positive charge on an oxygen atom, which would be a highly unstable species.

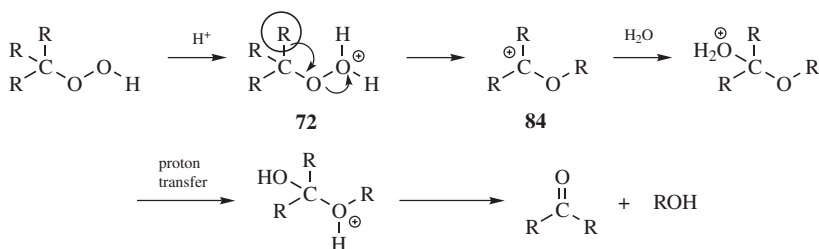

18-20 Rearrangement of Hydroperoxides

C-Alkyl-O-hydroxy-elimination

Hydroperoxides (R = alkyl, aryl, or hydrogen) can be cleaved by proton or Lewis acids in a reaction whose principal step is a rearrangement.³⁷⁶ The reaction has also been applied to peroxy esters (R₃COOCOR'), but less often. When aryl and alkyl groups are both present, migration of aryl dominates. It is not necessary actually to prepare and isolate hydroperoxides. The reaction takes place when the alcohols are treated with H₂O₂ and acids. Migration of an alkyl group of a primary hydroperoxide provides a means for converting an alcohol to its next lower homolog (RCH₂OOH → CH₂=O + ROH).

The mechanism is as follows:³⁷⁷

The last step is hydrolysis of the unstable hemiacetal. Alkoxy-carbocation intermediates (**84**, R = alkyl) have been isolated in super acid solution³⁷⁸ at

³⁷⁴Palmer, B.W.; Fry, A. *J. Am. Chem. Soc.* **1970**, *92*, 2580. See also, Mitsuhashi, T.; Miyadera, H.; Simamura, O. *Chem. Commun.* **1970**, 1301. For secondary isotope-effect studies, see Winnik, M.A.; Stoute, V.; Fitzgerald, P. *J. Am. Chem. Soc.* **1974**, *96*, 1977.

³⁷⁵In some cases, the rate-determining step has been shown to be the addition of peracid to the substrate (see, e.g., Ogata, Y.; Sawaki, Y. *J. Org. Chem.* **1972**, *37*, 2953). Even in these cases it is still highly probable that migration is concerted with departure of the nucleofuge.

low temperatures, and their structures proved by nmr.³⁷⁹ The protonated hydroperoxides could not be observed in these solutions, evidently reacting immediately on formation.

OS V, 818.

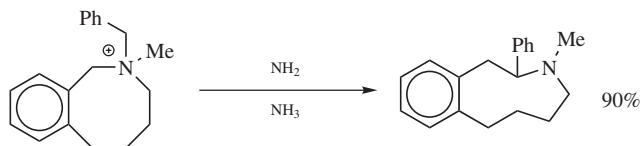

E. Nitrogen-to-Carbon, Oxygen-to-Carbon, and Sulfur-to-Carbon Migration

18-21 The Stevens Rearrangement

Hydron-(2/N → 1/alkyl)-migrat-detachment

In the *Stevens rearrangement*, a quaternary ammonium salt containing an electron-withdrawing group Z on one of the carbons attached to the nitrogen is treated with a strong base (e.g., NaOR or NaNH₂) to give a rearranged tertiary amine. The Z group may be RCO, ROOC, or phenyl.³⁸⁰ The most common migrating groups are allylic, benzylic, benzhydryl, 3-phenylpropargyl, and phenacyl, though even methyl migrates to a sufficiently negative center.³⁸¹ When an allylic group migrates, it may or may not involve an allylic rearrangement within the migrating group (see **18-35**), depending on the substrate and reaction conditions. The reaction has been used for ring enlargement,³⁸² for example:

The mechanism has been the subject of much study.³⁸³ That the rearrangement is intramolecular was shown by crossover experiments, by ¹⁴C labeling,³⁸⁴ and by the

fact that retention of configuration is found at R^1 .³⁸⁵ The first step is loss of the acidic proton to give the ylid **85**, which has been isolated.³⁸⁶ The finding³⁸⁷ that CIDNP spectra³⁸⁸ could be obtained in many instances shows that in these cases the product is formed directly from a free-radical precursor. The following radical pair mechanism was proposed:³⁸⁹

Mechanism *a*

The radicals do not drift apart because they are held together by the solvent cage. According to this mechanism, the radicals must recombine rapidly in order to account for the fact that R^1 does not racemize. Other evidence in favor of mechanism *a* is that in some cases small amounts of coupling products (R^1 - R^1) have been isolated,³⁹⁰ which would be expected if some $\bullet R^1$ leaked from the solvent cage. However, not all the evidence is easily compatible with mechanism *a*.³⁹¹ It is possible that another mechanism (*b*) similar to mechanism *a*, but involving

Mechanism *b*

ion pairs in a solvent cage instead of radical pairs, operates in some cases. A third possible mechanism would be a concerted 1,2-shift,³⁹² but the orbital symmetry

³⁹²For evidence against this mechanism, see Jenny, E.F.; Druey, J. *Angew. Chem. Int. Ed.* **1962**, *1*, 155.

principle requires that this take place with inversion at R¹.³⁹³ (see p. 1654.) Since the actual migration takes place with retention, it cannot, according to this argument, proceed by a concerted mechanism. However, in the case where the migrating group is allylic, a concerted mechanism can also operate (**18-35**). An interesting finding compatible with all three mechanisms is that optically active allylbenzylmethylphenylammonium iodide (asymmetric nitrogen, see p. 142) gave an optically active product:³⁹⁴

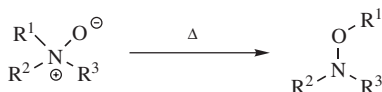

The *Sommelet-Hauser rearrangement* competes when Z is an aryl group (see **13-31**). *Hofmann elimination* competes when one of the R groups contains a β hydrogen atom (**17-7** and **17-8**).

Sulfur ylids containing a Z group give an analogous rearrangement, often also referred to as a Stevens

rearrangement.³⁹⁵ In this case too, there is much evidence (including CIDNP) that a radical-pair cage mechanism is operating,³⁹⁶ except that when the migrating group is allylic, the mechanism may be different (see **18-35**). Another reaction with a similar mechanism³⁹⁷ is the *Meisenheimer rearrangement*,³⁹⁸ in which certain tertiary

amine oxides rearrange on heating to give substituted hydroxylamines.³⁹⁹ The migrating group R¹ is almost always allylic or benzylic.⁴⁰⁰ R² and R³ may be alkyl or aryl, but if one of the R groups contains a β hydrogen, Cope elimination (**17-9**) often competes. In a related reaction, when 2-methylpyridine *N*-oxides are treated with trifluoroacetic anhydride, the *Boekelheide reaction* occurs to give 2-hydroxymethylpyridines.⁴⁰¹

Certain tertiary benzylic amines, when treated with BuLi, undergo a rearrangement analogous to the Wittig rearrangement (**18-22**), for example, PhCH₂NPh₂ → Ph₂CHNHPh.⁴⁰² Only aryl groups migrate in this reaction.

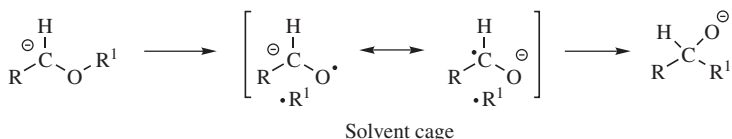

Isocyanides, when heated in the gas phase or in nonpolar solvents, undergo a 1,2-intramolecular rearrangement to nitriles: RNC → RCN.⁴⁰³ In polar solvents the mechanism is different.⁴⁰⁴

18-22 The Wittig Rearrangement⁴⁰⁵

Hydron-(2/O → 1/alkyl)-migr-o-detachment

The rearrangement of ethers with alkyllithium reagents is called the *Wittig rearrangement* (not to be confused with the Wittig reaction, **16-44**) and is similar to **18-21**.³⁸⁰ However, a stronger base is required (e.g., phenyllithium or sodium amide). The R and R' groups, may be alkyl,⁴⁰⁶ aryl, or vinylic.⁴⁰⁷ Also, one of the hydrogens may be replaced by an alkyl or aryl group, in which case the product is the salt of a tertiary alcohol. Migratory aptitudes

³⁹⁹For example, see Buston, J.E.H.; Coldham, I.; Mulholland, K.R. *Tetrahedron Asymmetry*, **1998**, 9, 1995.

⁴⁰⁰Migration of aryl and of certain alkyl groups has also been reported. See Khuthier, A.; Al-Mallah, K.Y.; Hanna, S.Y.; Abdulla, N.I. *J. Org. Chem.* **1987**, 52, 1710, and references cited therein.

⁴⁰⁶See Bailey, W.F.; England, M.D.; Mealy, M.J.; Thongsornkleeb, C.; Teng, L. *Org. Lett.* **2000**, 2, 489.

⁴⁰⁷For migration of vinyl, see Rautenstrauch, V.; Büchi, G.; Wüest, H. *J. Am. Chem. Soc.* **1974**, 96, 2576. For rearrangement of an α-trimethylsilyl allyl ether, see Maleczka, Jr., R.E.; Geng, F. *Org. Lett.* **1999**, 1, 1115.

here are allylic, benzylic > ethyl > methyl > phenyl.⁴⁰⁸ The stereospecificity of the 1,2-Wittig rearrangement has been discussed.⁴⁰⁹ The following radical-pair mechanism⁴¹⁰ (similar to mechanism *a* of **18-21**) is likely, after removal of the proton by the base. One of the radicals in the radical pair is a ketyl. Among the evidence for this mechanism is (1) the rearrangement is largely intramolecular; (2) migratory aptitudes are in the order of free-radical stabilities, not of carbanion stabilities⁴¹¹ (which rules out an ion-pair mechanism similar to mechanism *b* of **18-21**); (3) aldehydes are obtained as side products;⁴¹² (4) partial racemization of R' has been observed⁴¹³ (the remainder of the product retained its configuration); (5) crossover products have been detected;⁴¹⁴ and (6) when ketyl radicals and R radicals from different precursors were brought together, similar products resulted.⁴¹⁵ However, there is evidence that at least in some cases the radical-pair mechanism accounts for only a portion of the product, and some kind of concerted mechanism can also take place.⁴¹⁶ Most of the above investigations were carried out with systems where R' is alkyl, but a radical-pair mechanism has also been suggested for the case where R' is aryl.⁴¹⁷ When R' is allylic a concerted mechanism can operate (**18-35**).

When R is vinylic it is possible, by using a combination of an alkyllithium and *t*-BuOK, to get migration to the γ carbon (as well as to the α carbon), producing an enolate that, on hydrolysis, gives an aldehyde:⁴¹⁸

An aza-Wittig rearrangement is also known.⁴¹⁹

F. Boron-to-Carbon Migrations⁴²⁰

For another reaction involving boron-to-carbon migration, see **10-73**.

18-23 Conversion of Boranes to Alcohols

Trialkylboranes (which can be prepared from alkenes by **15-16**) react with carbon monoxide⁴²¹ at 100–125°C in the presence of ethylene glycol to give the 2-bora-1,3-dioxolanes (**86**), which are easily oxidized (**12-27**) to tertiary alcohols.⁴²² The R groups may be primary, secondary, or tertiary, and may be the same or different.⁴²³ Yields are high and the reaction is quite useful, especially for the preparation of sterically hindered alcohols, such as tricyclohexylcarbinol (**87**) and tri-2-norbornylcarbinol (**88**), which are difficult to prepare by **16-24**. Heterocycles in which boron is a ring atom react similarly (except that high CO pressures are required), and cyclic alcohols can be obtained from these substrates.⁴²⁴ The preparation of such heterocyclic boranes was discussed at **15-16**. The overall conversion of a diene or triene to a cyclic alcohol has been described by H.C. Brown as “stitching” with boron and “riveting” with carbon.

Though the mechanism has not been investigated thoroughly, it has been shown to be intramolecular by the failure to find crossover products when mixtures of boranes are used.⁴²⁵ The following scheme, involving three boron-to-carbon migrations, has been suggested.

The purpose of the ethylene glycol is to intercept the boronic anhydride **90**, which otherwise forms polymers that are difficult to oxidize. As we will see in **18-23** and **18-24**, it is possible to stop the reaction after only one or two migrations have taken place.

There are two other methods for achieving the conversion $\text{R}_3\text{B} \rightarrow \text{R}_3\text{COH}$, which often give better results: (1) treatment with α,α -dichloromethyl methyl ether and the base lithium triethylcarboxide⁴²⁶ (2) treatment with a suspension of sodium cyanide in THF followed by reaction of the resulting trialkylcyano-borate **91** with an excess (>2 equivalents) of trifluoroacetic anhydride.⁴²⁷ All the above migrations take place with retention of configuration at the migrating carbon.⁴²⁸

Several other methods for the conversion of boranes to tertiary alcohols are also known.⁴²⁹

If the reaction between trialkylboranes and carbon monoxide (**18-23**) is carried out in the presence of water followed by addition of NaOH, the product is a secondary alcohol. If H_2O_2 is added along with the NaOH, the corresponding ketone is obtained instead.⁴³⁰ Various functional groups (e.g., OAc, COOR, CN) may be

present in R without being affected,⁴³¹ though if they are in the α or β position relative to the boron atom, difficulties may

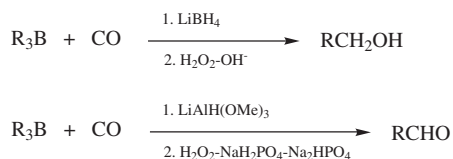

be encountered. The use of an equimolar amount of trifluoroacetic anhydride leads to the ketone rather than the tertiary alcohol.^{427,432} By this procedure, thexylboranes ($\text{RR}'\text{R}^2\text{B}$, where $\text{R}^2 = \text{thexyl}$) can be converted to unsymmetrical ketones (RCOR').⁴³³ Variations of this methodology have been used to prepare optically active alcohols.⁴³⁴

For another conversion of trialkylboranes to ketones (see **18-26**).⁴³⁵ Other conversions of boranes to secondary alcohols are also known.⁴³⁶

OS VII, 427. Also see, OS VI, 137.

18-24 Conversion of Boranes to Primary Alcohols, Aldehydes, or Carboxylic Acids

When the reaction between a trialkylborane and carbon monoxide (**18-23**) is carried out in the presence of a reducing agent such as lithium borohydride or potassium triisopropoxyborohydride, the reduction agent intercepts the intermediate **89**, so that only one boron-to-carbon migration takes place, and the product is hydrolyzed to a primary alcohol or oxidized to an aldehyde.⁴³⁷ This procedure wastes two of the three R groups, but this problem can be avoided by the use of

B-alkyl-9-BBN derivatives (p. 1077). Since only the 9-alkyl group migrates, this method permits the conversion in high yield of an alkene to a primary alcohol or aldehyde containing one more carbon.⁴³⁸ When B-alkyl-9-BBN derivatives are treated with CO and lithium tri-*tert*-butoxyaluminum hydride,⁴³⁹ other functional groups (e.g., CN and ester) can be present in the alkyl group without being reduced.⁴⁴⁰ Boranes can be directly converted to carboxylic acids by reaction with the dianion of phenoxyacetic acid.⁴⁴¹

Boronic esters $\text{RB}(\text{OR}')_2$ react with methoxy(phenylthio)methyl lithium $\text{LiCH}(\text{OMe})\text{SPh}$ to give salts, which, after treatment with HgCl_2 , and then H_2O_2 , yield aldehydes.⁴⁴² This synthesis has been made enantioselective, with high ee values (>99%), by the use of an optically pure boronic ester,⁴⁴³ for example:

18-25 Conversion of Vinylic Boranes to Alkenes

The reaction between trialkylboranes and iodine to give alkyl iodides was mentioned at **12-31**. When the substrate contains a vinylic group, the reaction takes a different course,⁴⁴⁴ with one of the R' groups migrating to the carbon, to give alkenes.⁴⁴⁵ The reaction is stereospecific in two senses: (*I*) if the groups

⁴⁴⁵For a list of methods of preparing alkenes using boron reagents, with references, see Larock, R.C. *Comprehensive Organic Transformations*, 2nd ed., Wiley-VCH, NY, **1999**, pp. 421–427.

R and R' are cis in the starting compound, they will be trans in the product; (2) there is retention of configuration within the migrating group R'.⁴⁴⁶ Since vinylic boranes can be prepared from alkynes (**15-16**), this is a method for the addition of R' and H to a triple bond. If R² = H, the product is a (Z)-alkene. The mechanism is believed to involve an iodonium intermediate, such as **92**, and attack by iodide on boron. When R' is vinylic, the product is a conjugated diene.⁴⁴⁷

In another procedure, the addition of a dialkylborane to a 1-haloalkyne produces an α -halo vinylic borane (**93**).⁴⁴⁸ Treatment of this with NaOMe gives the rearrangement shown, and protonolysis of the product

produces the (E)-alkene.⁴⁴⁶ If R is a vinylic group the product is a 1,3-diene.⁴⁴⁹ If one of the groups is hexyl, the other migrates.⁴⁵⁰ This extends the scope of the synthesis, since dialkylboranes where one R group is hexyl are easily prepared. A combination of both of the procedures described above results in the preparation of trisubstituted alkenes.⁴⁵¹ The entire conversion of haloalkyne to alkene can be carried out in one reaction vessel, without isolation of intermediates. An aluminum counterpart of the α -halo vinylic borane procedure has been reported.⁴⁵²

18-26 Formation of Alkynes, Alkenes, and Ketones from Boranes and Acetylides

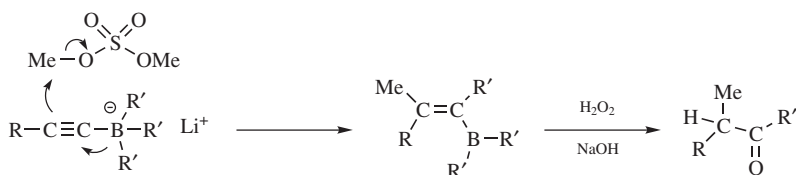

A hydrogen directly attached to a triple-bond carbon can be replaced in high yield by an alkyl or an aryl group, by treatment of the lithium acetylide with a trialkyl- or triarylborane, followed by reaction of the lithium alkynyltrialkylborate **94** with iodine.⁴⁵³ The R' group may be primary or secondary alkyl as well as aryl, so the reaction has a broader scope than the older reaction **10-74**.⁴⁵⁴ The R group may be alkyl, aryl, or hydrogen, though in the last-mentioned case satisfactory yields are obtained only if lithium acetylide–ethylenediamine is used as the starting

compound.⁴⁵⁵ Optically active alkynes can be prepared by using optically active hexylborinates (RR^3BOR^2 , $\text{R}^2 = \text{hexyl}$), where R is chiral, and $\text{LiC}\equiv\text{CSiMe}_3$.⁴⁵⁶ The reaction can be adapted to the preparation of alkenes⁴¹⁴ by treatment of **94** with an electrophile such as propanoic acid⁴⁵⁷ or tributyltin chloride.⁴⁵⁸ The reaction with Bu_3SnCl produces the (Z)-alkene stereoselectively.

Treatment of **94** with an electrophile, such as methyl sulfate, allyl bromide, or triethyloxonium borofluoride, followed by oxidation of the resulting vinylic borane gives a ketone (illustrated for methyl sulfate):⁴⁵⁹

NON-1,2 REARRANGEMENTS

A. Electrocyclic Rearrangements

18-27 Electrocyclic Rearrangements of Cyclobutenes and 1,3-Cyclohexadienes

(4)*seco*-1/4/Detachment; (4)*cyclo*-1/4/Attachment

(6)*seco*-1,6/Detachment; (6)*cyclo*-1/6/Attachment

Cyclobutenes and 1,3-dienes can be interconverted by treatment with uv light or with heat.⁴⁶¹ The thermal reaction is generally not reversible (although exceptions⁴⁶² are known), and many cyclobutenes have been converted to 1,3-dienes by heating at temperatures between 100 and 200°C. The photochemical conversion can in principle be carried out in either direction, but most often 1,3-dienes are converted to cyclobutenes rather than the reverse, because the dienes are stronger absorbers of light at the wavelengths used.⁴⁶³ In a similar reaction, 1,3-cyclohexadienes interconvert with 1,3,5-trienes, but in this case the ring-closing process is generally favored thermally and the ring-opening process photochemically, though exceptions are known in both directions.⁴⁶⁴ Substituent effects can lead to acceleration of the electrocyclozation process.⁴⁶⁵ Torquoselectivity in cyclobutene ring opening reaction has been examined.⁴⁶⁶

These reactions, called *electrocyclic rearrangements*,⁴⁷¹ take place by pericyclic mechanisms. The evidence comes from stereochemical studies, which show a remarkable stereospecificity whose direction depends on whether the reaction is induced by heat or light. For example, it was found for the thermal reaction that *cis*-3,4-dimethylcyclobutene gave only *cis,trans*-2,4-hexadiene, while the *trans* isomer gave only the *trans-trans* diene.⁴⁷²

This is evidence for a four-membered cyclic transition state and arises from conrotatory motion about the C-3–C-4 bond.⁴⁷³ It is called conrotatory because both movements are clockwise (or both counterclockwise). Because both rotate in the same direction, the *cis* isomer gives the *cis-trans* diene:⁴⁷⁴

The other possibility (*disrotatory* motion) would have one moving clockwise while the other moves counterclockwise; the *cis* isomer would have given the *cis-cis*

⁴⁷³The mechanism of cyclobutene thermal isomerization has been examined. See Baldwin, J.E.; Gallagher, S.S.; Leber, P.A.; Raghavan, A.S.; Shukla, R. *J. Org. Chem.* **2004**, *69*, 7212.

⁴⁷⁴This picture is from Woodward, R.B.; Hoffmann, R. *J. Am. Chem. Soc.* **1965**, *87*, 395, who coined the terms, *conrotatory* and *disrotatory*.

diene (shown) or the trans–trans diene:

If the motion had been disrotatory, this would still have been evidence for a cyclic mechanism. If the mechanism were a diradical or some other kind of noncyclic process, it is likely that no stereospecificity of either kind would have been observed. The reverse reaction is also conrotatory. In contrast, the photochemical cyclobutene: 1,3-Diene interconversion is *disrotatory* in either direction.⁴⁷⁵ On the other hand, the cyclohexadiene: 1,3,5-Triene interconversion shows precisely the opposite behavior. The thermal process is *disrotatory*, while the photochemical process is *conrotatory* (in either direction). These startling results are a consequence of the symmetry rules mentioned in Chapter 15 (p. 1208).⁴⁷⁶ As in the case of cycloaddition reactions, we will use the frontier orbital and Möbius–Hückel approaches.⁴⁷⁷

The Frontier Orbital Method⁴⁷⁸

As applied to these reactions, the frontier orbital method may be expressed: *A σ bond will open in such a way that the resulting p orbitals will have the symmetry of the highest occupied π orbital of the product.* In the case of cyclobutenes, the HOMO of the product in the thermal reaction is the χ_2 orbital (Fig. 18.1).

⁴⁷⁵Photochemical ring opening of cyclobutenes can also be nonstereospecific. See Leigh, W.J.; Zheng, K. *J. Am. Chem. Soc.* **1991**, *113*, 4019; Leigh, W.J.; Zheng, K.; Nguyen, N.; Werstiuk, N.H.; Ma, J. *J. Am. Chem. Soc.* **1991**, *113*, 4993, and references cited therein.

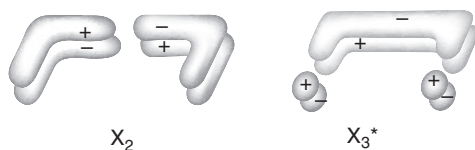

Fig. 18.1. Symmetries of the X_2 and X_3^* orbitals of a conjugated diene.

Therefore, in a thermal process, the cyclobutene must open so that on one side the positive lobe lies above the plane, and on the other side below it. Thus the substituents are forced into conrotatory motion (Fig. 18.2). On the other hand, in the photochemical process, the HOMO of the product is now the χ_3 orbital (Fig. 18.1), and in order for the p orbitals to achieve this symmetry (the two plus lobes on the same side of the plane), the substituents are forced into disrotatory motion.

We may also look at this reaction from the opposite direction (ring closing). For this direction, the rule is that *those lobes of orbitals that overlap (in the HOMO) must be of the same sign*. For thermal cyclization of butadienes, this requires conrotatory motion (Fig. 18.3). In the photochemical process the HOMO is the χ_3 orbital, so that disrotatory motion is required for lobes of the same sign to overlap.

The Möbius–Hückel Method⁴⁸¹

As we saw on p. 1210, in this method we choose a basis set of p orbitals and look for sign inversions in the transition state. Figure 18.4 shows a basis set for a 1,3-diene. It is seen that disrotatory ring closing (Fig. 18.4a) results in overlap of plus lobes only, while in conrotatory closing (Fig. 18.4b) there is one overlap of a plus

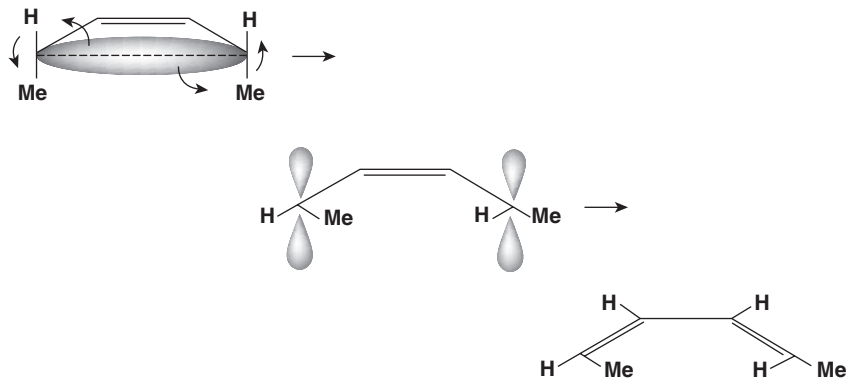

Fig. 18.2. Thermal opening of 1,2-dimethylcyclobutene. The two hydrogens and two methyls are forced into conrotatory motion so that the resulting p orbitals have the symmetry of the HOMO of the diene.

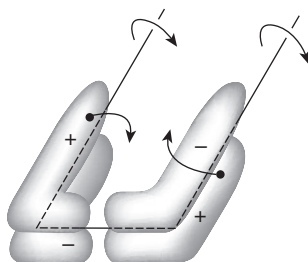

Fig. 18.3. Thermal ring closing of a 1,3-diene. Conrotatory motion is required for two + lobes to overlap.

with a minus lobe. In the first case, we have zero sign inversions, while in the second there is one sign inversion. With zero (or an even number of) sign inversions, the disrotatory transition state is a Hückel system, and so is allowed thermally only if the total number of electrons is $4n + 2$ (p. 1211). Since the total here is 4, the

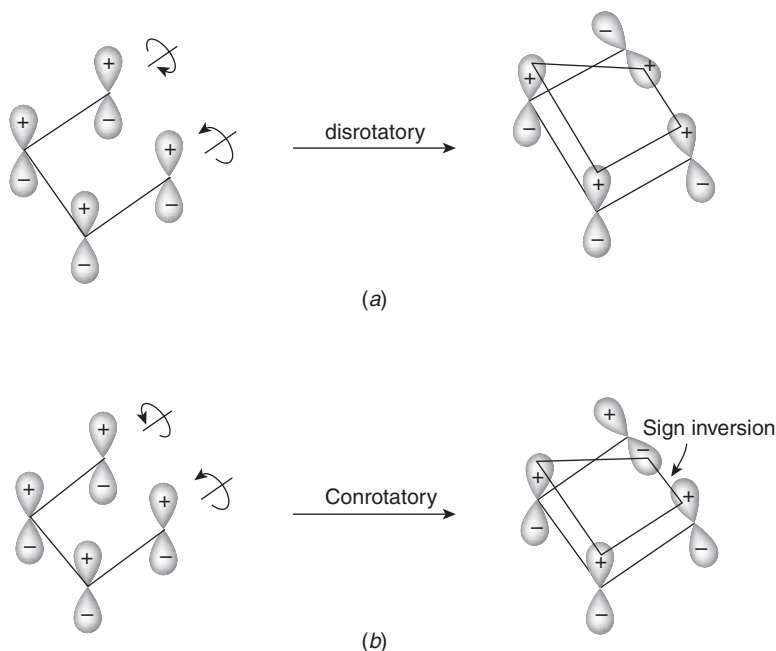

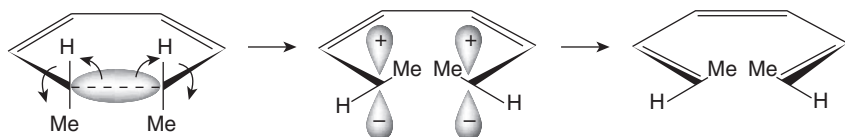

Fig. 18.4. The 1,3-diene–cyclobutene interconversion. The orbitals shown are *not* molecular orbitals, but a basis set of *p*-atomic orbitals. (a) Disrotatory ring closure gives zero sign inversion. (b) Conrotatory ring closure gives one sign inversion. We could have chosen to show any other basis set (e.g., another basis set would have two plus lobes above the plane and two below, etc.). This would change the number of sign inversion, but the disrotatory mode would still have an even number of sign inversions, and the conrotatory mode an odd number, whichever basis set was chosen.

disrotatory process is not allowed. On the other hand, the conrotatory process, with one sign inversion, is a Möbius system, which is thermally allowed if the total number is $4n$. The conrotatory process is therefore allowed thermally. For the photochemical reactions, the rules are reversed: A reaction with $4n$ electrons requires a Hückel system, so only the disrotatory process is allowed.

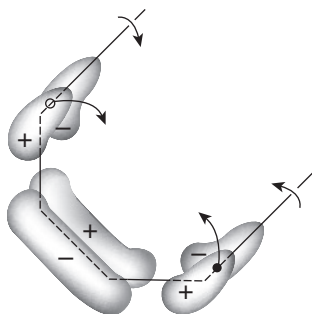

Both the frontier orbital and the Möbius–Hückel methods can also be applied to the cyclohexadiene: 1,3,5-triene reaction;⁴⁷⁹ in either case the predicted result is that for the thermal process, only the disrotatory pathway is allowed, and for the photochemical process, only the conrotatory. For example, for a 1,3,5-triene, the symmetry of the HOMO is

In the thermal cleavage of cyclohexadienes, then, the positive lobes must lie on the same side of the plane, requiring disrotatory motion:

Disrotatory motion is also necessary for the reverse reaction, in order that the orbitals that overlap may be of the same sign:

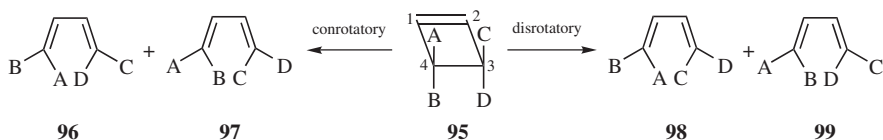

⁴⁷⁹For a discussion of the transition structures and energy, see Zora, M. *J. Org. Chem.* **2004**, *69*, 1940.

All these directions are reversed for photochemical processes, because in each case a higher orbital, with inverted symmetry, is occupied.

In the Möbius–Hückel approach, diagrams similar to Fig. 18.4 can be drawn for this case. Here too, the disrotatory pathway is a Hückel system and the conrotatory pathway a Möbius system, but since six electrons are now involved, the thermal reaction follows the Hückel pathway and the photochemical reaction the Möbius pathway.

In the most general case, there are four possible products that can arise from a given cyclobutene or cyclohexadiene: two from the conrotatory and two from the disrotatory pathway. For example, conrotatory ring opening of **95** gives either **96** or **97**, while disrotatory opening gives either **98** or **99**. The orbital-symmetry rules tell us when a given reaction will operate by the conrotatory and when by the disrotatory mode, but they do not say which of the two possible conrotatory or disrotatory pathways will be followed. It is often possible,

however, to make such predictions on steric grounds. For example, in the opening of **95** by the disrotatory pathway, **98** arises when groups A and C swing in toward each other (clockwise motion around C-4, counterclockwise around C-3), while **99** is formed when groups B and D swing in and A and C swing out (clockwise motion around C-3, counterclockwise around C-4). We therefore predict that when A and C are larger than B and D, the predominant or exclusive product will be **99**, rather than **98**. Predictions of this kind have largely been borne out.⁴⁸⁰ There is evidence, however, that steric effects⁴⁸¹ are not the only factor, and that electronic effects also play a role, which may be even greater.⁴⁸² An electron-donating group stabilizes the transition state when it rotates *outward*, because it mixes with the LUMO; if it rotates *inward*, it mixes with the HOMO, destabilizing the transition state.⁴⁸³ The compound 3-formylcyclobutene provided a test. Steric factors would cause the CHO

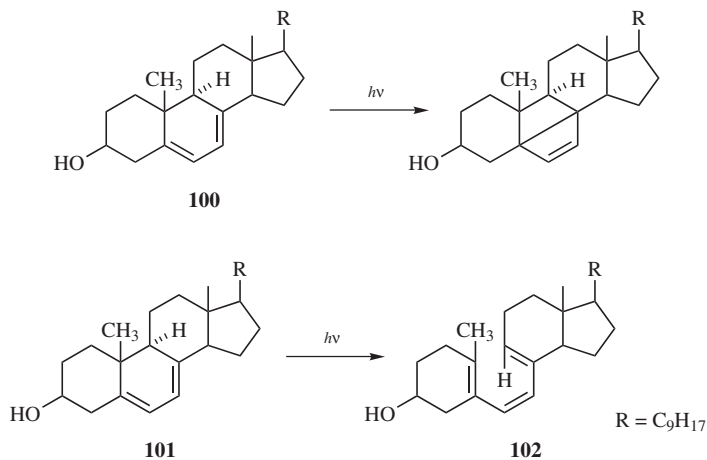

⁴⁸⁰For example, see Baldwin, J.E.; Krueger, S.M. *J. Am. Chem. Soc.* **1969**, *91*, 6444; Spangler, C.W.; Hennis, R.P. *J. Chem. Soc., Chem. Commun.* **1972**, 24; Gesche, P.; Klinger, F.; Riesen, A.; Tschamber, T.; Zehnder, M.; Streith, J. *Helv. Chim. Acta* **1987**, *70*, 2087.

⁴⁸³For theoretical studies, see Buda, A.B.; Wang, Y.; Houk, K.N. *J. Org. Chem.* **1989**, *54*, 2264; Kallel, E.A.; Wang, Y.; Spellmeyer, D.C.; Houk, K.N. *J. Am. Chem. Soc.* **1990**, *112*, 6759.

(an electron-withdrawing group) to rotate outward; electronic effects would cause it to rotate inward. The experiment showed inward rotation.⁴⁸⁴

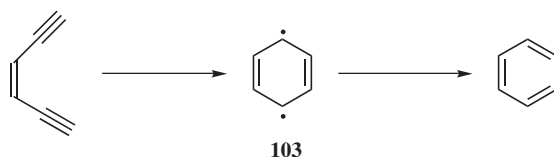

Cyclohexadienes are of course 1,3-dienes, and in certain cases it is possible to convert them to cyclobutenes instead of to 1,3,5-trienes.⁴⁸⁵ An interesting example is found in the pyrocalciferols. Photolysis of the syn isomer **100** (or of the other syn isomer, not shown) leads to the corresponding cyclobutene,⁴⁸⁶ while photolysis of the anti isomers (one of them is **101**) gives the ring-opened 1,3,5-triene, **102**. This difference in behavior is at first sight remarkable, but is easily explained by the orbital-symmetry rules. Photochemical ring opening to a 1,3,5-triene must be conrotatory. If **100** were to react by this pathway, the product would be the triene **102**, but this compound would have to contain a *trans*-cyclohexene ring (either the methyl group or the hydrogen would have to be directed inside the ring). On the other hand, photochemical conversion to a cyclobutene must be disrotatory, but if **101** were to give this reaction, the product would have to have a *trans*-fused ring junction. Compounds with such ring junctions are known (p. 188), but are very strained. Stable *trans*-cyclohexenes are unknown (p. 226). Thus, **100** and **101** give the products they do owing to a combination of orbital-symmetry rules and steric influences.

⁴⁸⁵For a discussion of the factors favoring either direction, see Dauben, W.G.; Kellogg, M.S.; Seeman, J.I.; Vietmeyer, N.D.; Wendschuh, P.H. *Pure Appl. Chem.* **1973**, *33*, 197.

⁴⁸⁶Dauben, W.G.; Fonken, G.J. *J. Am. Chem. Soc.* **1959**, *81*, 4060. This was the first reported example of the conversion of a 1,3-diene to a cyclobutene.

A variation of this process is the *Bergmann cyclization*,⁴⁸⁷ where an ene-diyne cyclizes to a biradical (**103**) and then aromatizes as shown.

Simply heating the ene-diyne will usually lead to aromatization via this pathway.⁴⁸⁸ Quinones can be formed via Bergman cyclization⁴⁸⁹ and there are other synthetic applications.⁴⁹⁰ The role of vinyl substitution has been examined.⁴⁹¹ An aza-Bergman cyclization is known.⁴⁹²

The 1,3-diene-cyclobutene interconversion can even be applied to benzene rings. For example,⁴⁹³ photolysis of 1,2,4-tri-*tert*-butylbenzene (**104**) gives

⁴⁹³Unsubstituted Dewar benzene has been obtained, along with other photoproducts, by photolysis of benzene: Ward, H.R.; Wishnok, J.S. *J. Am. Chem. Soc.* **1968**, *90*, 1085; Bryce-Smith, D.; Gilbert, A.; Robinson, D.A. *Angew. Chem. Int. Ed.* **1971**, *10*, 745. For other examples, see Arnett, E.M.; Bollinger, J.M. *Tetrahedron Lett.* **1964**, 3803; Camaggi, G.; Gozzo, F.; Cevidalli, G. *Chem. Commun.* **1966**, 313; Haller, I. *J. Am. Chem. Soc.* **1966**, *88*, 2070; *J. Chem. Phys.* **1967**, *47*, 1117; Barlow, M.G.; Haszeldine, R.N.; Hubbard, R. *Chem. Commun.* **1969**, 202; Lemal, D.M.; Staros, J.V.; Austel, V. *J. Am. Chem. Soc.* **1969**, *91*, 3373.

1,2,5-tri-*tert*-butyl[2.2.0]hexadiene (**105**, a Dewar benzene).⁴⁹⁴ The reaction owes its success to the fact that once **105** is formed, it cannot, under the conditions used, revert to **104** by either a thermal or a photochemical route. The orbital-symmetry rules prohibit thermal conversion of **105** to **104** by a pericyclic mechanism, because thermal conversion of a cyclobutene to a 1,3-diene must be conrotatory, and conrotatory reaction of **105** would result in a 1,3,5-cyclohexatriene containing one *trans* double bond (**106**), which is of course too strained to exist. Compound **105** cannot revert to **104** by a photochemical pathway either, because light of the frequency used to excite **104** would not be absorbed by **105**. This is thus another example of a molecule that owes its stability to the orbital-symmetry rules (see p. 1232). Pyrolysis of **105** does give **104**, probably by a diradical mechanism.⁴⁹⁵ In the case of **107** and **108**, the Dewar benzene is actually more stable than the benzene. Compound **107** rearranges to **108** in 90% yield at 120°C.⁴⁹⁶ In this case, thermolysis of the benzene gives the Dewar benzene (rather than the reverse), because of the strain of four adjacent *tert*-butyl groups on the ring.

A number of electrocyclic reactions have been carried out with systems of other sizes, for example, conversion of the 1,3,5,7-octatetraene **109** to the cyclooctatriene **110**.⁴⁹⁷ The stereochemistry of these reactions can be predicted in a

⁴⁹⁴Wilzbach, K.E.; Kaplan, L. *J. Am. Chem. Soc.* **1965**, *87*, 4004; van Tamelen, E.E.; Pappas, S.P.; Kirk, K.L. *J. Am. Chem. Soc.* **1971**, *93*, 6092; van Tamelen, E.E. *Acc. Chem. Res.* **1972**, *5*, 186. As mentioned on p. \$\$\$ (Lemal, D.M.; Lokensgard, J.P. *J. Am. Chem. Soc.* **1966**, *88*, 5934; Schäfer, W.; Criegee, R.; Askani, R.; Grüner, H. *Angew. Chem. Int. Ed.* **1967**, *6*, 78), Dewar benzenes can be photolyzed further to give prismanes.

⁴⁹⁵See, for example, Oth, J.F.M. *Recl. Trav. Chim. Pays-Bas* **1968**, *87*, 1185; Adam, W.; Chang, J.C. *Int. J. Chem. similar manner. The results of such predictions can be summarized according to whether the number of electrons involved in the cyclic process is of the form $4n$ or $4n + 2$ (where n is any integer including zero).

	Thermal Reaction	Photochemical Reaction
$4n$	Conrotatory	Disrotatory
$4n + 2$	Disrotatory	Conrotatory

Although the orbital-symmetry rules predict the stereochemical results in almost all cases, it is necessary to recall (p. 1210) that they only say what is allowed and what is forbidden, but the fact that a reaction is allowed does not necessarily mean that the reaction takes place, and if an allowed reaction does take place, it does not *necessarily* follow that a concerted pathway is involved, since other pathways of lower energy may be available.⁴⁹⁸ Furthermore, a “forbidden” reaction might still be made to go, if a method of achieving its high activation energy can be found. This was, in fact, done for the cyclobutene butadiene interconversion (*cis*-3,4-dichlorocyclobutene gave the forbidden *cis*-, *cis*- and *trans*, *trans*-1,4-dichloro-1,3-butadienes, as well as the allowed *cis*, *trans* isomer) by the use of ir laser light.⁴⁹⁹ This is a thermal reaction. The laser light excites the molecule to a higher vibrational level (p. 330), but not to a higher electronic state.

As is the case for [2+2]-cycloaddition reactions (**15-63**), certain forbidden electrocyclic reactions can be made to take place by the use of metallic catalysts.⁵⁰⁰ An example is the silver ion-catalyzed conversion of tricyclo[4.2.0.0^{2,5}]octa-3,7-diene to cyclooctatetraene:⁵⁰¹

This conversion is very slow thermally (i.e., without the catalyst) because the reaction must take place by a disrotatory pathway, which is disallowed thermally.⁵⁰² In another example, the major thermal product from the barrelene anion is a

rearranged allyl anion that is formed by disrotatory cleavage of the cyclopropyl ring, a formally Woodward–Hoffmann-forbidden process.⁵⁰³

The ring opening of cyclopropyl cations (pp. 486, 1591) is an electrocyclic reaction and is governed by the orbital symmetry rules.⁵⁰⁴ For this case, we invoke the rule that the s bond opens in such a way that the resulting p orbitals have the symmetry of the highest occupied orbital of the product, in this case, an allylic cation. We may recall that an allylic system has three molecular orbitals (p. 42). For the cation, with only two electrons, the highest occupied orbital is the one of the lowest energy (A). Thus, the cyclopropyl cation must undergo a

disrotatory ring opening in order to maintain the symmetry. (Note that, in contrast, ring opening of the cyclopropyl *anion* must be conrotatory,⁵⁰⁵ since in this case it is the next orbital of the allylic system that is the highest occupied, and this has the opposite symmetry.⁵⁰⁶) However, it is very difficult to generate a free cyclopropyl cation (p. 487), and it is likely that in most cases, cleavage of the σ bond is concerted with departure of the leaving group in the original cyclopropyl substrate. This, of course, means that the σ bond provides anchimeric assistance to the removal of the leaving group (an S_N2 -type process), and we would expect that such assistance should come from the back side. This has an important effect on the direction of ring opening. The orbital-symmetry rules require that the ring opening be disrotatory, but as we have seen, there are two disrotatory pathways and the rules do not tell us which is preferred. But the fact that the s orbital provides assistance from the backside means that the two substituents that are trans to the leaving group must move *outward*, not inward.⁵⁰⁷ Thus, the disrotatory pathway that is followed is the one shown in B, not the one shown in C, because the former puts the electrons of the σ bond on the

Ed.* **1977**, *16*, 572.

⁵⁰⁷This was first proposed by DePuy, C.H.; Schnack, L.G.; Hausser, J.W.; Wiedemann, W. *J. Am. Chem. Soc.* **1965**, *87*, 4006.

side opposite that of the leaving group.⁵⁰⁸ Strong confirmation of this picture⁵⁰⁹ comes from acetolysis of *endo*- (**111**) and *exo*-bicyclo[3,1,0]hexyl-6-tosylate (**112**). The groups trans to the tosylate must move outward. For **111**, this means that the two hydrogens can go outside the framework of the six-membered ring, but for **112** they

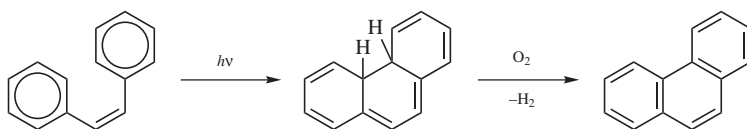

are forced to go inside. Consequently, it is not surprising that the rate ratio for solvolysis of **111/112** was found to be $>2.5 \times 10^6$ and that at 150°C **112** did not solvolyze at all.⁵¹⁰ This evidence is kinetic. Unlike the cases of the cyclobutene (1,3-diene and cyclohexadiene) 1,3,5-triene interconversions, the direct product here is a cation, which is not stable but reacts with a nucleophile and loses some of its steric integrity in the process, so that much of the evidence has been of the kinetic type rather than from studies of product stereochemistry. However, it has been shown by investigations in superacids, where it is possible to keep the cations intact and to study their structures by NMR, that in all cases studied the cation that is predicted by these rules is in fact formed.⁵¹¹

Pd-C,⁵¹³ or iodine.⁵¹⁴ The reaction is a photochemically allowed conrotatory⁵¹⁵ conversion of a 1,3,5-hexatriene to a cyclohexadiene, followed by removal of two hydrogen atoms by the oxidizing agent. The intermediate dihydrophenanthrene has been isolated.⁵¹⁶ The use of substrates containing heteroatoms (e.g., PhN=NPh) allows the formation of heterocyclic ring systems. The actual reacting species must be the *cis*-stilbene, but *trans*-stilbenes can often be used, because they are isomerized to the *cis* isomers under the reaction conditions. The reaction can be extended to the preparation of many fused aromatic systems, for example,⁵¹⁷

though not all such systems give reaction.⁵¹⁸

Isomerization of biphenylene to benzo[*a*]pentalene⁵¹⁹ is a well-known benzene ring contraction rearrangement,⁵²⁰ driven by relief of strain in the four-membered ring. Related to this process is the FVP of the alternant polycyclic aromatic hydrocarbon benzo[*b*]biphenylene at 1100°C, which gives fluoranthene, a nonalternant polycyclic aromatic hydrocarbon, as the major product at 1100°C in the gas phase.⁵²¹ The mechanism used explain that this isomerization involves equilibrating diradicals of 2-phenylnaphthalene, which rearrange by the net migration of a phenyl group to give equilibrating diradicals of 1-phenylnaphthalene, one isomer of which then cyclizes to fluoranthene.

Another transformation of one aromatic compound to another is the *Stone–Wales rearrangement* of pyracyclene (**113**),⁵²² which is a bond-switching reaction. The rearrangement of bifluorenylidene (**114**) to dibenzo[*g,p*]chrysene (**115**) occurs at temperatures as low as 400°C and is accelerated in the presence of decomposing iodomethane, a convenient source of methyl radicals.⁵²³ This result suggested a

radical rearrangement. This rearrangement is believed to occur by a radical-promoted mechanism consisting of a sequence of homoallyl–cyclopropylcarbinyl rearrangement steps.⁵²⁴

B. Sigmatropic Rearrangements

A sigmatropic rearrangement is defined⁵²⁵ as migration, in an uncatalyzed intramolecular process, of a σ bond, adjacent to one or more π systems, to a new position in a molecule, with the π systems becoming reorganized in the process. Examples are

The *order* of a sigmatropic rearrangement is expressed by two numbers set in brackets: $[i,j]$. These numbers can be determined by counting the atoms over which each end of the σ bond has moved. Each of the original termini is given the number 1. Thus in the first example above, each terminus of the σ bond has

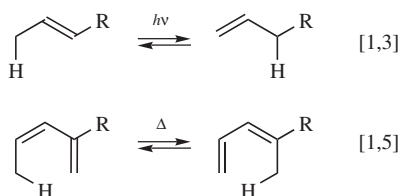

⁵²⁴Alder, R.W.; Harvey, J. N. *J. Am. Chem. Soc.* **2004**, *126*, 2490.

⁵²⁵Woodward, R.B.; Hoffmann, R. *The Conservation of Orbital Symmetry*, Academic Press, NY, **1970**, p. 114.

migrated from C-1 to C-3, so the order is [3,3]. In the second example, the carbon terminus has moved from C-1 to C-5, but the hydrogen terminus has not moved at all, so the order is [1,5].

18-29 [1,*j*]-Sigmatropic Migrations of Hydrogen

1/ → 3/Hydrogen-migration; 1/ → 5/Hydrogen-migration

Many examples of thermal or photochemical rearrangements in which a hydrogen atom migrates from one end of a system of π bonds to the other have been reported,⁵²⁶ although the reaction is subject to geometrical conditions. Isotope effects play a role in sigmatropic rearrangements, and there is evidence for a kinetic silicon isotope effect.⁵²⁷ Pericyclic mechanisms are involved,⁵²⁸ and the hydrogen must, in the transition state, be in contact with both ends of the chain at the same time. This means that for [1,5] and longer rearrangements, the molecule must be able to adopt the cisoid conformation. Furthermore, there are two geometrical pathways by which any sigmatropic rearrangement can take place, which we illustrate for the case of a [1,5]-sigmatropic rearrangement,⁵²⁹ starting with a substrate of the form **116**, where the migration origin is an asymmetric carbon atom and $U \neq V$. In one of the two pathways, the hydrogen moves along the top or bottom face of the π system. This is called *suprafacial migration*. In the other pathway, the hydrogen moves *across* the π system, from top to bottom, or vice versa. This is *antarafacial migration*. Altogether, a single isomer like **116** (different rotamers) can give four products. In a suprafacial migration, H can move across the top of the π system (as drawn above) to give the (*R,Z*) isomer, or it can rotate 180° and move across the bottom of the π system to give the (*S,E*) isomer.⁵³⁰ The antarafacial migration can similarly lead to two diastereomers, in

⁵²⁶For a monograph, see Gajewski, J.J. *Hydrocarbon Thermal Isomerizations*, Academic Press, NY, **1981**. For reviews, see Mironov, V.A.; Fedorovich, A.D.; Akhrem, A.A. *Russ. Chem. Rev.* **1981**, *50*, 666; Spangler, C.W. *Chem. ⁵²⁷Lin, Y.-L.; Turos, E. *J. Am. Chem. Soc.* **1999**, *121*, 856.

⁵²⁸For a discussion of catalysts that induce pericyclic rearrangements, see Moss, S.; King, B.T.; de Meijere, A.; Kozhushkov, S.I.; Eaton, P.E.; Michl, J. *Org. Lett.* **2001**, *3*, 2375.

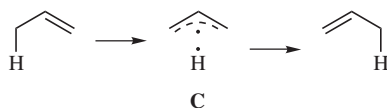

⁵²⁹Note that a [1,5]-sigmatropic rearrangement of hydrogen is also an internal ene synthesis (**15-20**).

⁵³⁰Since we are using the arbitrary designations U, V, Y, and Z, we have been arbitrary in which isomer to call (*R,Z*) and which to call (*S,E*).

this case the (*S,Z*) and (*R,E*) isomers.

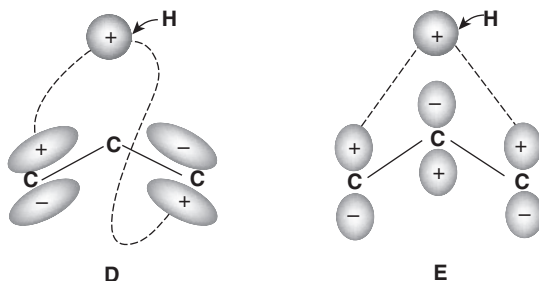

In any given sigmatropic rearrangement, only one of the two pathways is allowed by the orbital-symmetry rules; the other is forbidden. To analyze this situation, first we use a modified frontier orbital approach.⁵³¹ We will imagine that in the transition state **C**, the migrating H atom breaks away from the rest of the system, which we may treat as if it were a free radical.

Imaginary
transition state
for a [1,3]-
sigmatropic
rearrangement

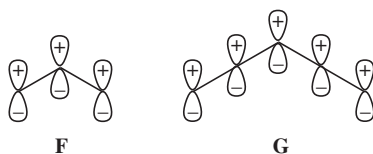

⁵³¹See Woodward, R.B.; Hoffmann, R. *The Conservation of Orbital Symmetry*, Academic Press, NY, 1970, pp. 114–140.

Note that this is not what actually takes place; we merely imagine it in order to be able to analyze the process. In a [1,3]-sigmatropic rearrangement, the imaginary transition state consists of a hydrogen atom and an allyl radical. The latter species (p. 42) has three π orbitals, but the only one that concerns us here is the HOMO which, in a thermal rearrangement is **D**. The electron of the hydrogen atom is of course in a $1s$ orbital, which has only one lobe. The rule governing sigmatropic migration of hydrogen is *the H must move from a plus to a plus or from a minus to a minus*

lobe, of the HOMO; it cannot move to a lobe of opposite sign.⁵³² Obviously, the only way this can happen in a thermal [1,3]-sigmatropic rearrangement is if the migration is antarafacial. Consequently, the rule predicts that antarafacial thermal [1,3]-sigmatropic rearrangements are allowed, but the suprafacial pathway is forbidden. However, in a photochemical reaction, promotion of an electron means that **E** is now the HOMO; the suprafacial pathway is now allowed and the antarafacial pathway forbidden.

A similar analysis of [1,5]-sigmatropic rearrangements shows that in this case the thermal reaction must be suprafacial and the photochemical process antarafacial. For the general case, with odd-numbered j , we can say that [1, j]-suprafacial migrations are allowed thermally when j is of the form $4n + 1$, and photochemically when j has the form $4n - 1$; the opposite is true for antarafacial migrations.

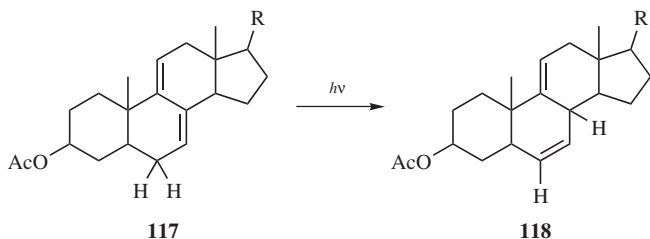

As expected, the Möbius–Hückel method leads to the same predictions. Here, we look at the basis set of orbitals shown in **F** and **G** for [1,3]- and [1,5]-rearrangements, respectively. A [1,3]-shift involves four electrons, so an allowed thermal pericyclic reaction must be a Möbius system (p. 1210) with one or an odd number

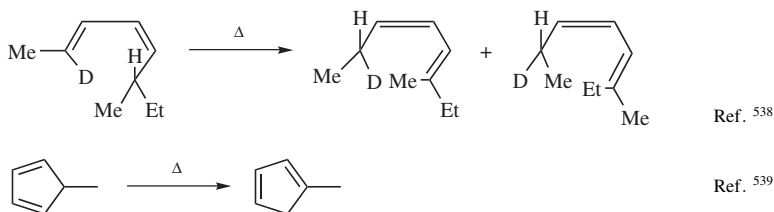

⁵³²This follows from the principle that bonds are formed only by overlap of orbitals of the same sign. Since this is a concerted reaction, the hydrogen orbital in the transition state must overlap simultaneously with one lobe from the migration origin and one from the terminus. It is obvious that both of these lobes must have the same sign.

of sign inversions. As can be seen in **F**, only an antarafacial migration can achieve this. A [1,5]-shift, with six electrons, is allowed thermally only when it is a Hückel system with zero or an even number of sign inversions; hence it requires a suprafacial migration.⁵³³

The actual reported results bear out this analysis. Thus a thermal [1,3] migration is allowed to take place only antarafacially, but such a transition state would be extremely strained, and thermal [1,3]-sigmatropic migrations of hydrogen are unknown.⁵³⁴ On the other hand, the photochemical pathway allows suprafacial [1,3]-shifts, and a few such reactions are known, an example being the photochemical rearrangement of **117** to **118**.⁵³⁵ Substituents influence the efficacy of the [1,3]-hydrogen shift.⁵³⁶

The situation is reversed for [1,5]-hydrogen shifts. In this case the thermal rearrangements, being suprafacial, are quite common, while photochemical rearrangements are rare.⁵³⁷ Two examples of the thermal reaction are

⁵³³For a discussion of the origins for the preference for orbital-symmetry forbidden reactions and the stereochemistry of [1,5]-sigmatropic shifts, see Kless, A.; Nendel, M.; Wilsey, S.; Houk, K.N. *J. Am. Chem. Soc.* **1999**, *121*, 4524.

⁵³⁴A possible [1,3]-migration of hydrogen has been reported. See Yeh, M.; Linder, L.; Hoffman, D.K.; Barton, T.J. *J. Am. Chem. Soc.* **1986**, *108*, 7849. See also, Pasto, D.J.; Brophy, J.E. *J. Org. Chem.* **1991**, *56*, 4554.

⁵³⁹McLean, S.; Haynes, P. *Tetrahedron* **1965**, *21*, 2329. For a review of such rearrangements, see Klärner, F. *Top. Stereochem.* **1984**, *15*, 1. For a discussion of [1,5]-sigmatropic hydrogen shifts in cyclic 1,3-dienes, see Hess, Jr., B.A.; Baldwin, J.E. *J. Org. Chem.* **2002**, *67*, 6025.

Note that the first example bears out the stereochemical prediction made earlier. Only the two isomers shown were formed. In the second example, migration can continue around the ring. Migrations of this kind are called *circumambulatory rearrangements*.⁵⁴⁰ Such migrations are known for cyclopentadiene, pyrrole, and phosphole derivatives.⁵⁴¹ Geminal bond participation has been observed in penta-dienes,⁵⁴² the effects of phenyl substituents have been studied,⁵⁴³ and the kinetics and activation parameters of [1,5] hydrogen shifts have been examined.⁵⁴⁴ The [1,5] hydrogen shifts are also known with vinyl aziridines.⁵⁴⁵

The rare [1,4]-hydrogen transfer has been observed in radical cyclizations.⁵⁴⁶ With respect to [1,7]-hydrogen shifts, the rules predict the thermal reaction to be antarafacial.⁵⁴⁷ Unlike the case of [1,3]-shifts, the transition state is not too greatly strained, and an example of such rearrangements is the formation of **119** and **120**.⁵⁴⁸ Photochemical [1,7]-shifts are suprafacial and, not surprisingly, many of these have been observed.⁵⁴⁹

The orbital symmetry rules also help us to explain, as on pp. 1232 and 1642, the unexpected stability of certain compounds. Thus, **120** could, by a thermal [1,3]-sigmatropic rearrangement, easily convert to toluene, which of course is far more stable because it has an aromatic sextet. Yet, **120** has been prepared and is stable at dry ice temperature and in dilute solutions.⁵⁵⁰

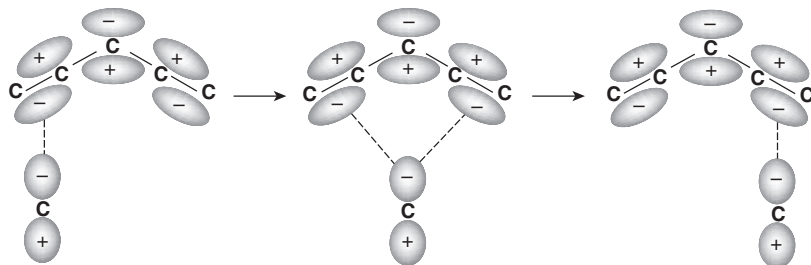

Fig. 18.5. Hypothetical orbital movement for a thermal [1,5]-sigmatropic migration of carbon. To move from one negative lobe, the migrating carbon uses only its own negative lobe, retaining its configuration.

Sigmatropic migrations of alkyl or aryl groups⁵⁵⁶ are less common than the corresponding hydrogen migrations.⁵⁵⁷ When they do take place, there is an important difference. Unlike a hydrogen atom, whose electron is in a $1s$ orbital with only one lobe, a carbon free radical has its odd electron in a p orbital that has *two lobes of opposite sign*. Therefore, if we draw the imaginary transition states for this case (see p. 1650), we see that in a thermal suprafacial [1,5] process (Fig. 18.5), symmetry can be conserved only if the migrating carbon moves in such a way that the lobe which was originally attached to the π system remains attached to the π system.

This can happen only if configuration is *retained within the migrating group*. On the other hand, thermal suprafacial [1,3] migration (Fig. 18.6) *can* take place if the migrating carbon switches lobes. If the migrating carbon was originally bonded by its minus lobe, it must now use its plus lobe to form the new C–C bond. Thus, configuration in the migrating group will be *inverted*. From these considerations we predict that suprafacial [1, j]-sigmatropic rearrangements in which carbon is the migrating group are always allowed, both thermally and photochemically, but that thermal [1,3] migrations will proceed with inversion and thermal [1,5]

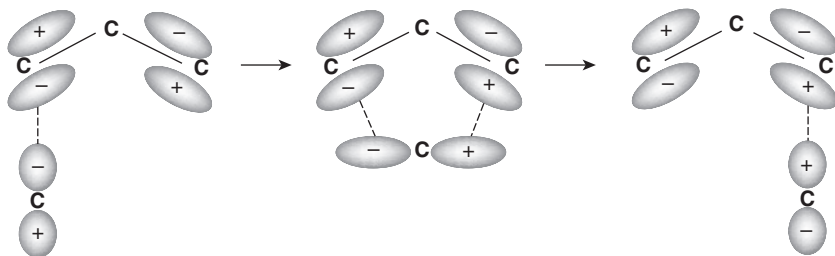

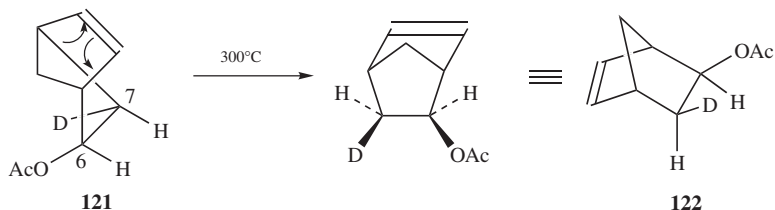

Fig. 18.6. Hypothetical orbital movement for a thermal [1,3]-sigmatropic migration of carbon. The migrating carbon moves a negative to a positive lobe, requiring it to switch its own bonding lobe from negative to positive, inverting its configuration.

⁵⁵⁶For reviews, see Mironov, V.A.; Fedorovich, A.D.; Akhrem, A.A. *Russ. Chem. Rev.* **1981**, *50*, 666; Spangler, C.W. *Chem. Rev.* **1976**, *76*, 187

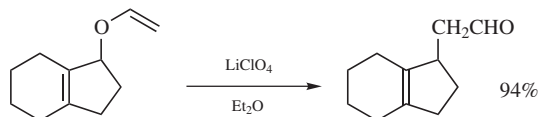

⁵⁵⁷It has been shown that methyl and phenyl have lower migratory aptitudes than hydrogen in thermal sigmatropic rearrangements: Shen, K.; McEwen, W.E.; Wolf, A.P. *Tetrahedron Lett.* **1969**, 827; Miller, L.L.; Greisinger, R.; Boyer, R.F. *J. Am. Chem. Soc.* **1969**, *91*, 1578.

migrations with retention of configuration within the migrating group. More generally, we can say that suprafacial $[1_j]$ migrations of carbon in systems where $j = 4n - 1$ proceed with inversion thermally and retention photochemically, while systems where $j = 4n + 1$ show the opposite behavior. Where antarafacial migrations take place, all these predictions are of course reversed.

The first laboratory test of these predictions was the pyrolysis of deuterated *endo*-bicyclo[3.2.0]hept-2-en-6-yl acetate (**121**), which gave the *exo*-deuterio-*exo*-norbonyl acetate **122**.⁵⁵⁸ Thus, as predicted by the orbital symmetry rules, this thermal suprafacial [1,3]-sigmatropic reaction took place with complete inversion at C-7. Similar results have been obtained in a number of other cases.⁵⁵⁹ However, similar studies of the pyrolysis of the parent hydrocarbon of **121**, labeled with D at C-6 and C-7, showed that while most of the product was formed with inversion at C-7, a significant fraction (11–29%) was formed with retention.⁵⁶⁰ Other cases of lack of complete inversion are also known.⁵⁶¹ A diradical mechanism has been invoked to explain such cases.⁵⁶² There is strong evidence for a radical mechanism for some [1,3]-sigmatropic rearrangements.⁵⁶³ Photochemical suprafacial [1,3] migrations of carbon have been shown to proceed with retention, as predicted.⁵⁶⁴

Although allylic vinylic ethers generally undergo [3,3]-sigmatropic rearrangements (**18-33**), they can be made to give the [1,3] kind, to give aldehydes, for example,

by treatment with LiClO_4 in diethyl ether.⁵⁶⁵ In this case, the C–O bond undergoes a 1,3 migration from the O to the end vinylic carbon. When the vinylic ether is of the type $\text{ROCR}'=\text{CH}_2$, ketones $\text{RCH}_2\text{COR}'$ are formed. There is evidence that this [1,3]-sigmatropic rearrangement is not concerted, but involves dissociation of the substrate into ions.⁵⁶⁵

Thermal suprafacial [1,5] migrations of carbon have been found to take place with retention,⁵⁶⁶ but also with inversion.⁵⁶⁷ A diradical mechanism has been suggested for the latter case.⁵⁶⁷

Simple nucleophilic, electrophilic, and free-radical 1,2-shifts can also be regarded as sigmatropic rearrangements (in this case, [1,2]-rearrangements). We have already (p. \$\$\$) applied similar principles to such rearrangements to show that nucleophilic 1,2-shifts are allowed, but the other two types are forbidden unless the migrating group has some means of delocalizing the extra electron or electron pair. The mechanism of the forbidden [3s,5s]-sigmatropic shift has been examined.⁵⁶⁸

18-31 Conversion of Vinylcyclopropanes to Cyclopentenes

The thermal expansion of a vinylcyclopropane to a cyclopentene ring⁵⁶⁹ is a special case of a [1,3]-sigmatropic migration of carbon, although it can also be considered an internal $[\pi 2 + \sigma 2]$ -cycloaddition reaction (see **15-63**). It is known as a *vinylcyclopropane rearrangement*.⁵⁷⁰ The reaction has been carried out on many vinylcyclopropanes bearing various substituents in the ring⁵⁷¹ or

on the vinyl group and has been extended to 1,1-dicyclopropylethene⁵⁷²

and (both thermally⁵⁷³ and photochemically⁵⁷⁴) to vinylcyclopropenes. This rearrangement can be catalyzed by rhodium and silver compounds, and has been used to form rings.⁵⁷⁵ Another variation converts α -trimethylsilylcyclopropyl ketones to ring-expanded ketones, such as **123**, via FVP at 550°C.⁵⁷⁶ Flash vacuum pyrolysis of the trimethylsilyl ether of cyclopropylcarbinyl alcohols gives similar results.⁵⁷⁷ A variation uses flash vacuum pyrolysis at 600°C to convert α -trimethylsilyloxy- α -vinyl cyclic ketones to ring expanded ketones.⁵⁷⁸

Various heterocyclic analogs⁵⁷⁹ are also known, as in the rearrangement of aziridinyl amides (**124**).⁵⁸⁰ Cyclopropyl ketones can be treated with tosylamine and a zirconium catalyst, which converts the imine formed *in situ* to a pyrroline.⁵⁸¹

Two competing reactions are the homodienyl [1,5]-shift (if a suitable H is available, see **18-29**), and simple cleavage of the cyclopropane ring, leading in this case to a diene (see **18-3**).

Vinylcyclobutanes can be similarly converted to cyclohexenes,⁵⁸² but larger ring compounds do not generally give the reaction.⁵⁸³ Bicyclo[2.1.0]pentane derivatives undergo this reaction, and tricyclo[4.1.0.0^{2,5}]heptanes rearrange to give non-conjugated cycloheptadienes.⁵⁸⁴ Though high temperatures (as high as 500°C) are normally required for the thermal reaction, the lithium salts of 2-vinylcyclopropanols rearrange to the lithium salt of cyclopent-3-enols at 25°C.⁵⁸⁵ Salts of 2-vinylcyclobutanols behave analogously.⁵⁸⁶

The reaction rate has also been greatly increased by the addition of a one-electron oxidant tris-(4-bromophenyl)aminium hexafluoroantimonate Ar₃N⁺SbF₆⁻ (Ar = *p*-bromophenyl).⁵⁸⁷ This reagent converts the substrate to a cation radical, which undergoes ring expansion much faster.⁵⁸⁸

The mechanisms of these ring expansions are not certain. Both concerted⁵⁸⁹ and diradical⁵⁹⁰ pathways have been proposed,⁵⁹¹ and it is possible that both pathways operate, in different systems.

For the conversion of a vinylcyclopropane to a cyclopentene in a different way, see OS **68**, 220.

A "continuous diradical transition state" has also been proposed: Roth, W.R.; Lennartz, H.; Doering, W. von E.; Birladeanu, L.; Guyton, C.A.; Kitagawa, T. *J. Am. Chem. Soc.* **1990**, *112*, 1722, and references cited therein.

⁵⁹¹For a discussion concerning whether or not this [1,3]-shift is a concerted reaction, see Gajewski, J.J.; Olson, L.P.; Willcott III, M.R. *J. Am. Chem. Soc.* **1996**, *118*, 299. For a discussion of the mechanism of this reaction, see Su, M.-D. *Tetrahedron* **1995**, *51*, 5871.

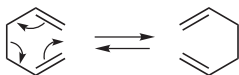

N-Cyclopropylimines undergo rearrangement to cyclic imines (pyrrolines) under photochemical conditions.⁵⁹² P-Vinyl phosphiranes (the P analog of cyclopropanes with P in the ring) under a similar rearrangement, and the mechanism has been studied.⁵⁹³

18-32 The Cope Rearrangement

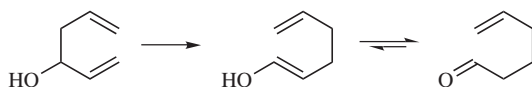

(3/4) → (1/6)-*sigma*-Migration

When 1,5-dienes are heated, a [3,3] sigmatropic rearrangement known as the *Cope rearrangement* (not to be confused with the Cope elimination reaction, **17-9**) occurs to generate an isomeric 1,5-diene.⁵⁹⁴ When the diene is symmetrical about the 3,4 bond, we have the unusual situation where a reaction gives a product identical with the starting material:⁵⁹⁵

Therefore, a Cope rearrangement can be detected only when the diene is not symmetrical about this bond. Any 1,5-diene gives the rearrangement; for example, 3-methyl-1,5-hexadiene heated to 300°C gives 1,5-heptadiene.⁵⁹⁶ However, the reaction takes place more easily (lower temperature required) when there is a group on the 3- or 4-carbon which leads to the new double bond being substituted. The reaction is obviously reversible⁵⁹⁷ and produces an equilibrium mixture of the two 1,5-dienes, which is richer in the thermodynamically more stable isomer. However, the equilibrium can be shifted to the right for 3-hydroxy-1,5-dienes,⁵⁹⁸ because the product tautomerizes to the ketone or aldehyde:

The reaction of 3-hydroxy-1,5-dienes is called the *oxy-Cope rearrangement*,⁵⁹⁹ and has proved highly useful in synthesis.⁶⁰⁰ The oxy-Cope rearrangement is greatly accelerated (by factors of 10^{10} – 10^{17}) if the alkoxide is used rather than the alcohol (the *anionic oxy-Cope rearrangement*),⁶⁰¹ where the direct product is the enolate ion, which is hydrolyzed to the ketone. A metal free reaction using a phosphazene base has been reported.⁶⁰² The silyloxy-Cope rearrangement has proven to be quite useful.⁶⁰³ An antibody-catalyzed oxy-Cope reaction is known,⁶⁰⁴ and the mechanism and origins of catalysis for this reaction have been studied.⁶⁰⁵ Sulfur substitution also leads to rate enhancement of the oxy-Cope rearrangement.⁶⁰⁶ Note that 2-oxonia Cope rearrangements have been implicated in Prins cyclization reactions (**16-54**).⁶⁰⁷

aza-Cope rearrangements are also known.⁶⁰⁸ In amino-Cope rearrangements, the solvent plays a role in the regioselectivity of the reaction.⁶⁰⁹ It has been suggested that this latter reaction does not proceed solely by a concerted [3.3]-sigmatropic rearrangement.⁶¹⁰

The 1,5-diene system may be inside a ring or part of an allenic system⁶¹¹ (this example illustrates both of these situations):⁶¹²

but the reaction does not take place when one of the double bonds is part of an aromatic system (e.g., 4-phenyl-1-butene).⁶¹³ When the two double bonds are in vinylic groups attached to adjacent ring positions, the product is a ring four carbons larger. This has been applied to divinylcyclopropanes and divinylcyclobutanes:⁶¹⁴

Indeed, *cis*-1,2-divinylcyclopropanes give this rearrangement so rapidly that they generally cannot be isolated at room temperature,⁶¹⁵ though exceptions are known.⁶¹⁶ When heated, 1,5-diynes are converted to 3,4-dimethylenecyclobutenes **125**.⁶¹⁷ A rate-determining Cope rearrangement is followed by a very rapid electrocyclic (**18-27**) reaction. The interconversion of 1,3,5-trienes and cyclohexadienes

Chem. Rep.* **1972**, *6*, 151.

(in **18-27**) is very similar to the Cope rearrangement, but in **18-27**, the 3,4 bond goes from a double bond to a single bond rather than from a single bond to no bond.

Like [2 + 2]-cycloadditions (p. 1220), Cope rearrangements of simple 1,5-dienes can be catalyzed by certain transition-metal compounds. For example, the addition of $\text{PdCl}_2(\text{PhCN})_2$ causes the reaction to take place at room temperature.⁶¹⁸ This can be quite useful synthetically, because of the high temperatures required in the uncatalyzed process.

As we have indicated with our arrows, the mechanism of the uncatalyzed Cope rearrangement is a simple six-centered pericyclic process.⁶¹⁹ Since the mechanism is so simple, it has been possible to study some rather subtle points, among them the question of whether the six-membered transition state is in the boat or the chair form.⁶²⁰ For the case of 3,4-dimethyl-1,5-hexadiene, it was demonstrated conclusively that the transition state is in the chair form. This was shown by the stereospecific nature of the reaction: The meso isomer gave the *cis*-*trans* product, while the (\pm) diastereomer gave the *trans*-*trans* diene.⁶²¹ If the transition state is in the chair form (taking the meso isomer, e.g.), one methyl must be "axial" and the other "equatorial" and the product must be the *cis*-*trans* alkene:

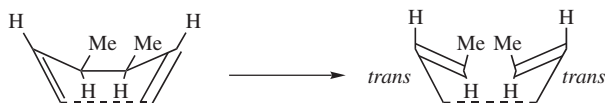

⁶¹⁸Overman, L.E.; Knoll, F.M. *J. Am. Chem. Soc.* **1980**, *102*, 865; Hamilton, R.; Mitchell, T.R.B.; Rooney, J.J. *J. Chem. Soc., Chem. Commun.* **1981**, 456. For a study of the mechanism, see Overman, L.E.; Renaldo, A.F. *J. Am. Chem. Soc.* **1990**, *112*, 3945.

⁶¹⁹For a mechanistic discussion, see Poupko, R.; Zimmermann, H.; Müller, K.; Luz, Z. *J. Am. Chem. Soc.* **1996**, *118*, 7995.

⁶²⁰For a discussion showing a preference for the chair conformation, see Shea, K.J.; Stoddard, G.J.; England, W.P.; Haffner, C.D. *J. Am. Chem. Soc.* **1992**, *114*, 2635. See also, Tantillo, D.J.; Hoffmann, R. *J. Org. Chem.* **2002**, *67*, 1419.

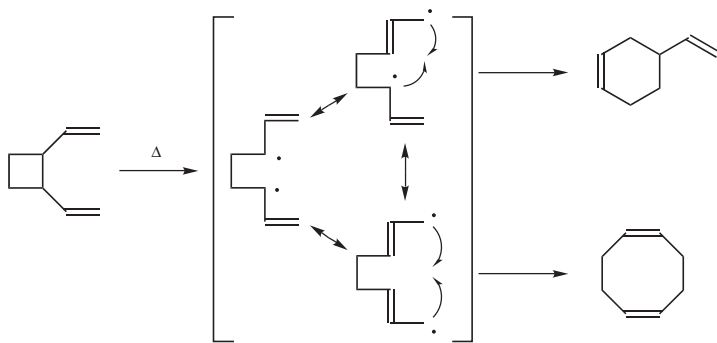

⁶²¹Doering, W. von E.; Roth, W.R. *Tetrahedron* **1962**, *18*, 67. See also, Hill, R.K.; Gilman, N.W. *Chem. Commun.* **1967**, 619; Goldstein, M.J.; DeCamp, M.R. *J. Am. Chem. Soc.* **1974**, *96*, 7356; Hansen, H.; Schmid, H. *Tetrahedron* **1974**, *30*, 1959; Gajewski, J.J.; Benner, C.W.; Hawkins, C.M. *J. Org. Chem.* **1987**, *52*, 5198; Paquette, L.A.; DeRussy, D.T.; Cottrell, C.E. *J. Am. Chem. Soc.* **1988**, *110*, 890.

There are two possible boat forms for the transition state of the meso isomer. One leads to a trans–trans product;

the other to a cis–cis alkene. For the (\pm) pair the predictions are just the opposite: There is just one boat form, and it leads to the cis–trans alkene, while one chair form (“diaxial” methyls) leads to the cis–cis product and the other (“diequatorial” methyls) predicts the trans–trans product. Thus the nature of the products obtained demonstrates that the transition state is a chair and not a boat.⁶²² While 3,4-dimethyl-1,5-hexadiene is free to assume either the chair or boat (it prefers the chair), other compounds are not so free. Thus 1,2-divinylcyclopropane (p. 1661) can react *only* in the boat form, demonstrating that such reactions are not impossible.⁶²³

Because of the nature of the transition state⁶²⁴ in the pericyclic mechanism, optically active substrates with a stereogenic carbon at C-3 or C-4 transfer the chirality to the product (see p. 1673 for an example in the mechanistically similar Claisen rearrangement).⁶²⁵ There are many examples of asymmetric [3,3]-sigmatropic rearrangements.⁶²⁶

⁶²²Preference for the chair transition state is a consequence of orbital-symmetry relationships: Hoffmann, R.; Woodward, R.B. *J. Am. Chem. Soc.* **1965**, *87*, 4389; Fukui, K.; Fujimoto, H. *Tetrahedron Lett.* **1966**, 251.

⁶²⁵For a review of Cope and Claisen reactions as enantioselective syntheses, see Hill, R.K., in Morrison, J.D. *Asymmetric Synthesis*, Vol. 3, Academic Press, NY, **1984**, pp. 503–572, 503–545.

⁶²⁶For a review, see Nubbemeyer, U. *Synthesis* **2003**, 961.

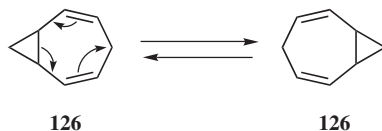

Not all Cope rearrangements proceed by the cyclic six-centered mechanism.⁶²⁷ Thus *cis*-1,2-divinylcyclobutane (p. 1661) rearranges smoothly to 1,5-cyclooctadiene, since the geometry is favorable. The *trans* isomer also gives this product, but the main product is 4-vinylcyclohexene (resulting from **18-31**). This reaction can be rationalized as proceeding by a diradical mechanism,⁶²⁸ although it is possible that at least part of the cyclooctadiene produced comes from a prior epimerization of the *trans*- to the *cis*-divinylcyclobutane followed by Cope rearrangement of the latter.⁶²⁹

It has been suggested that another type of diradical two-step mechanism may be preferred by some substrates.⁶³⁰ Indeed, a nonconcerted Cope rearrangement has been reported.⁶³¹ In this pathway,⁶³² the 1,6 bond is formed before the 3,4 bond breaks:

This is related to the *Bergman cyclization* that was introduced in **18-27**.

It was pointed out earlier that a Cope rearrangement of the symmetrical 1,5-hexadiene gives 1,5-hexadiene. This is a *degenerate Cope rearrangement* (p. 1563). Another molecule that undergoes it is bicyclo[5.1.0]octadiene

⁶²⁷The diradical character of the Cope rearrangement transition state has been studied. See Staroverov, V.B.; Davidson, E.R. *J. Am. Chem. Soc.* **2000**, *122*, 186; Navarro-Vázquez, A.; Prall, M.; Schreiner, P.R. *Org. Lett.* **2004**, *6*, 2981.

(**126**).⁶³³ At room temperature, the NMR spectrum of this compound is in accord with the structure shown on the left. At 180°C, it is converted by a Cope reaction to a compound equivalent to itself. The interesting thing is that at 180°C the NMR spectrum shows that what exists is an equilibrium mixture of the two structures. That is, at this temperature the molecule rapidly (faster than 10^3 times per second) changes back and forth between the two structures. This is called *valence tautomerism* and is quite distinct from resonance, even though only electrons shift.⁶³⁴ The positions of the nuclei are not the same in the two structures. Molecules like **126** that exhibit valence tautomerism (in this case, at 180°C) are said to have *fluxional* structures. It may be recalled that *cis*-1,2-divinylcyclopropane does not exist at room temperature because it rapidly rearranges to 1,4-cycloheptadiene (p. 1661), but in **126** the *cis*-divinylcyclopropane structure is frozen into the molecule in both structures. Several other compounds with this structural feature are also known. Of these, *bullvalene* (**127**) is especially interesting.

The Cope rearrangement shown changes the position of the cyclopropane ring from 4,5,10 to 1,7,8. But the molecule could also have undergone rearrangements to put this ring at 1,2,8 or 1,2,7. Any of these could then undergo several Cope rearrangements. In all, there are $\frac{10!}{3}$ or >1.2 million tautomeric forms, and the cyclopropane ring can be at any three carbons that are adjacent. Since each of these tautomers is equivalent to all the others, this has been called an infinitely degenerate Cope rearrangement. Bullvalene has been synthesized and its ^1H NMR spectrum determined.⁶³⁵ At -25°C , there are two peaks with an area ratio of 6:4. This is in accord with a single non-tautomeric structure. The six are the vinylic protons and the four are the allylic ones. But at 100°C the compound shows only one NMR peak, indicating that we have here a truly unusual situation where the compound rapidly interchanges its structure among 1.2 million equivalent forms.⁶³⁶ The ^{13}C NMR spectrum of bullvalene also shows

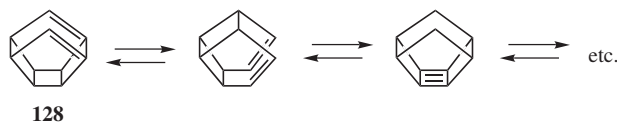

⁶³³Doering, W. von E.; Roth, W.R. *Tetrahedron* **1963**, *19*, 715.

⁶³⁴For reviews of valence tautomerizations, see Decock-Le Révérend, B.; Goudmand, P. *Bull. Soc. Chim. Fr.* **1973**, 389; Gajewski, J.J. *Mech. Mol. Migr.* **1971**, *4*, 1, see pp. 32–49; Paquette, L.A. *Angew. Chem. Int. Ed.* **1971**, *10*, 11; Domareva-Mandel'shtam, T.V.; D'yakonov, I.A. *Russ. Chem. Rev.* **1966**, *35*, 559, 568; Schröder, G.; Oth, J.F.M.; Merényi, R. *Angew. Chem. Int. Ed.* **1965**, *4*, 752.

⁶³⁶A number of azabullvalenes (**127** containing heterocyclic nitrogen) have been synthesized. They also have fluxional structures when heated, though with fewer tautomeric forms than bullvalene itself: Paquette, L.A.; Malpass, J.R.; Krow, G.R.; Barton, T.J. *J. Am. Chem. Soc.* **1969**, *91*, 5296.

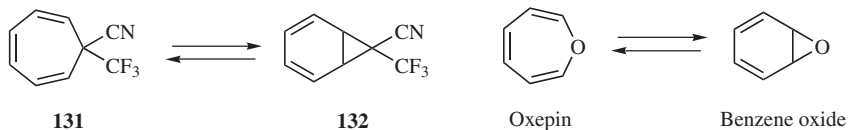

only one peak at 100°C.⁶³⁷

Another compound for which degenerate Cope rearrangements result in equivalence for all the carbons is *hypostrophene* (**128**).⁶³⁸ In the case of the compound *barbaralane* (**129**)⁶³⁹ (bullvalene in which one CH=CH has been replaced by a CH₂):

there are only 2 equivalent tautomers.⁶⁴⁰ However, NMR spectra indicate that even at room temperature a rapid interchange of both tautomers is present, although by about -100°C this has slowed to the point where the spectrum is in accord with a single structure. In the case of *semibullvalene* (**130**) (barbaralane in which the CH₂ has been removed), not only is there a rapid interchange at room temperature, but even at -110°C.⁶⁴¹ Compound **130** has the lowest energy barrier of any known compound capable of undergoing the Cope rearrangement.⁶⁴²

Soc.* **1974**, *96*, 2887; Moskau, D.; Aydin, R.; Leber, W.; Günther, H.; Quast, H.; Martin, H.-D.; Hassenrück, K.; Miller, L.S.; Grohmann, K. *Chem. Ber.* **1989**, *122*, 925. For a discussion concerning whether or not semibullvalenes are homoaromatic, see Williams, R.V.; Gadgil, V.R.; Chauhan, K.; Jackman, L.M.; Fernandes, E. *J. Org. Chem.* **1998**, *63*, 3302.

The molecules taking part in a valence tautomerization need not be equivalent. Thus, NMR spectra indicate that a true valence tautomerization exists at room temperature between the cycloheptatriene **131** and the norcaradiene **132**.⁶⁴³ In this case, one isomer (**132**) has the *cis*-1,2-divinylcyclopropane structure, while the other does not. In an analogous interconversion, benzene oxide⁶⁴⁴ and oxepin exist in a tautomeric equilibrium at room temperature.⁶⁴⁵

Bullvalene and hypostrophene are members of a group of compounds all of whose formulas can be expressed by the symbol $(\text{CH})_{10}$.⁶⁴⁶ Many other members of this group are known. Similar groups of $(\text{CH})_n$ compounds exist for other even-numbered values of “*n*”.⁶⁴⁶ For example, there are 20 possible $(\text{CH})_8$ compounds,⁶⁴⁸ and five possible $(\text{CH})_6$ compounds,⁶⁴⁹ all of which are known: benzene, prismane (p. 220), Dewar benzene (p. 1641), bicyclopropenyl,⁶⁵⁰ and benzvalene.⁶⁵¹

An interesting example of a valence tautomerism is the case of 1,2,3-tri-*tert*-butylcyclobutadiene (p. 74). There are two isomers, both rectangular, and ¹³C NMR spectra show that they exist in a dynamic equilibrium, even at -185°C .⁶⁵²

18-33 The Claisen Rearrangement⁶⁵³

Allylic aryl ethers, when heated, rearrange to *o*-allylphenols in a reaction called the *Claisen rearrangement*.⁶⁵⁴ If both ortho positions are filled, the allylic group migrates to the para position (this is often called the *para-Claisen rearrangement*).⁶⁵⁵ There is no reaction when the para and both ortho positions are filled. Migration to the meta position has not been observed. In the ortho migration, the allylic group always undergoes an allylic shift. That is, as shown above, a substituent α to the oxygen is now γ to the ring (and vice versa). On the other hand, in the para migration there is never an allylic shift: The allylic group is found exactly as it was in the original ether. Compounds with propargylic groups (i.e., groups with a triple bond in the appropriate position) do not generally give the corresponding products.

The mechanism is a concerted pericyclic [3,3]-sigmatropic rearrangement⁶⁵⁶ and accounts for all these facts. For the ortho rearrangement:

Evidence is the lack of a catalyst, the fact that the reaction is first order in the ether, the absence of crossover products when mixtures are heated, and the presence of the allylic shift, which is required by this mechanism. A *retro-Claisen* rearrangement is known and its mechanism has been examined.⁶⁵⁷ The allylic

⁶⁵⁷Boeckman, Jr., R.K.; Shair, M.D.; Vargas, J.R.; Stolz, L.A. *J. Org. Chem.* **1993**, *58*, 1295.

shift for the ortho rearrangement (and the absence of one for the para) has been demonstrated by ^{14}C labeling, even when no substituents are present. Studies of the transition-state geometry have shown that, like the Cope rearrangement, the Claisen rearrangement usually prefers a chair-like transition state.⁶⁵⁸ When the ortho positions have no hydrogen, a second [3,3]-sigmatropic migration (a Cope reaction) follows:

and the migrating group is restored to its original structure. Intermediates of structure **133** have been trapped by means of a Diels–Alder reaction.⁶⁵⁹ The rearrangement of aryl allyl ethers is facilitated by Ag–KI in hot acetic acid,⁶⁶⁰ and by AlMe_3 in water.⁶⁶¹ A solid-phase reaction of polymer-bound substrate undergoes the Claisen rearrangement with microwave irradiation.⁶⁶²

Allylic ethers of enols (allylic vinylic ethers) also undergo the Claisen rearrangement,⁶⁶³ in fact, it was discovered with these compounds first.⁶⁶⁴

In these cases of course, the final tautomerization does not take place even when $\text{R}' = \text{H}$, since there is no aromaticity to restore, and ketones are more stable than enols.⁶⁶⁵ Catalytic Claisen rearrangements of allyl vinyl ethers are well known.⁶⁶⁶

⁶⁶⁴Claisen, L. *Berchte.* **1912**, *45*, 3157.

⁶⁶⁵However, it has proved possible to reverse the reaction, with a Lewis acid catalyst. See Boeckman Jr., R.K.; Flann, C.J.; Poss, K.M. *J. Am. Chem. Soc.* **1985**, *107*, 4359.

⁶⁶⁶For a review, see Hiersemann, M.; Abraham, L. *Eur. J. Org. Chem.* **2002**, 1461.

The use of water as solvent accelerates the reaction.⁶⁶⁷ A microwave induced reaction on silica gel is known⁶⁶⁸. The mechanism is similar to that with allylic aryl ethers.⁶⁶⁹ Allyl allene ethers undergo a Claisen rearrangement when heated in DMF to give the expected diene with a conjugated aldehyde unit.⁶⁷⁰ Butenolides with a β -allylic ether unit undergo Claisen rearrangement–Conia reaction⁶⁷¹ cascade to give an oxaspiro heptane with β -keto lactone comprising the five-membered ring.⁶⁷² Allylic esters of β -keto acids undergo a Claisen rearrangement in what is known as the *Carroll rearrangement*⁶⁷³ (also called the *Kimel–Cope rearrangement*⁶⁷⁴), and the reaction can be catalyzed by a ruthenium complex.⁶⁷⁵

It is possible to treat ketones with allyl alcohol and an acid catalyst to give γ,δ -unsaturated ketones directly, presumably by initial formation of the vinylic ethers, and then Claisen rearrangement.⁶⁷⁶ In an analogous procedure, the enolates (**134**) of allylic esters [formed by treatment of the esters with lithium isopropylcyclohexylamide (LICA)] rearrange to γ,δ -unsaturated acids.⁶⁷⁷ Allylic alcohols can be treated with a catalytic amount of mercuric acetate, and in the presence of an excess of allyl vinyl ethers give an alkene–aldehyde via a Claisen rearrangement.⁶⁷⁸

⁶⁷⁸Tokuyama, H.; Makido, T.; Ueda, T.; Fukuyama, T. *Synth. Commun.* **2002**, *32*, 869.

Alternatively, the silylketene acetal $R^3R^2C=C(OSiR_3)OCH_2CH=CHR^1$ is often used instead of **134**.^{677,679} This rearrangement also proceeds at room temperature. By either procedure, the reaction is called the *Ireland–Claisen rearrangement*.⁶⁸⁰ Note the presence of the negative charge in **134**. As with the oxy-Cope rearrangement (in **18-34**), negative charges generally accelerate the Claisen reaction,⁶⁸¹ although the extent of the acceleration can depend on the identity of the positive counterion.⁶⁸² The reaction proceeds with good syn selectivity in many cases.⁶⁸³ The Ireland–Claisen rearrangement has been made enantioselective by converting **134** to an enol borinate in which the boron is attached to a chiral group.⁶⁸⁴ The Ireland–Claisen rearrangement can be done with amide derivatives also.⁶⁸⁵

A number of expected analogs of the Claisen rearrangement are known, for example, rearrangement of $ArNHCH_2CH=CH_2$,⁶⁸⁶ of *N*-allylic enamines ($R_2C=CRNCR_2CR=CR_2$),⁶⁸⁷ of allylic imino esters, $RC(OCH_2CH=CH_2)=NR$ ⁶⁸⁸ (these have often been rearranged with transition-metal catalysts⁶⁸⁹), and of $RCH=NRCHRCH_2CH=CH_2$. These rearrangements of nitrogen-containing compounds can be called *aza-Claisen rearrangements*,⁶⁹⁰ but are often called

*aza-Cope rearrangements*⁶⁹¹ as described in **18-34**. However, a palladium catalyzed aza-Claisen has been reported.⁶⁹² A so-called amine-Claisen rearrangement was reported for *N*-allyl indoles, when heated in the presence of $\text{BF}_3 \cdot \text{OEt}_2$.⁶⁹³ An *azo-Cope* rearrangement: $\text{CH}_2=\text{CHCR}_2^1 \text{CR}_2^2 \text{N}=\text{NAr} \rightarrow \text{R}_2^1 \text{C}=\text{CHCH}_2\text{NArN}=\text{CR}_2^2$ has been reported.⁶⁹⁴ Propargylic vinylic compounds give allenic aldehydes, ketones, esters, or amides.⁶⁹⁵

The conversion of allylic aryl thioethers $\text{ArSCH}_2\text{CH}=\text{CH}_2$ to *o*-allylic thiophenols is not feasible, because the latter are not stable,⁶⁹⁶ but react to give bicyclic compounds.⁶⁹⁷ However, many allylic vinylic sulfides do give the rearrangement (the *thio-Claisen rearrangement*).⁶⁹⁸ Allylic vinylic sulfones, for example, $\text{H}_2\text{C}=\text{CRCH}_2\text{-SO}_2\text{-CH}=\text{CH}_2$, rearrange, when heated in the presence of ethanol and pyridine, to unsaturated sulfonate salts $\text{CH}_2=\text{CRCH}_2\text{CH}_2\text{CH}_2\text{SO}_3^-$, produced by reaction of the reagents with the unstable sulfene intermediates $\text{CH}_2=\text{CRCH}_2\text{CH}_2\text{CH}=\text{SO}_2$.⁶⁹⁹ Allylic vinylic sulfoxides rapidly rearrange at room temperature or below.⁷⁰⁰

As mentioned for the Ireland-Claisen rearrangement, asymmetric Claisen rearrangement reactions are well known.⁷⁰¹ Chiral Lewis acids have been designed for

this purpose.⁷⁰² In general, asymmetric [3,3]-sigmatropic rearrangements are well known.⁷⁰³

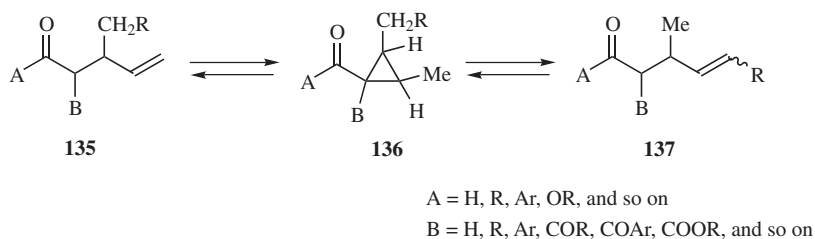

Ethers with an alkyl group in the γ position (ArO-C-C=C-R systems) sometimes give abnormal products, with the β carbon becoming attached to the ring:⁷⁰⁴

It has been established that these abnormal products do not arise directly from the starting ether, but are formed by a further rearrangement of the normal product:⁷⁰⁵

This rearrangement, which has been called an *enolene rearrangement*, a *homo-dienyl [1,5]-sigmatropic hydrogen shift* (see **18-29**), and a *[1,5]-homosigmatropic rearrangement*, involves a shift of three electron pairs over *seven* atoms. It has been found that this “abnormal” Claisen rearrangement is general and can interconvert the enol forms of systems of the types **135** and **136** through the cyclopropane intermediate **137**.⁷⁰⁶

Since the Claisen rearrangement mechanism does not involve ions, it should not be greatly dependent on the presence or absence of substituent groups on the ring.⁷⁰⁷ This is the case. Electron-donating groups increase the rate and electron-withdrawing groups decrease it, but the effect is small, with the *p*-amino compound reacting only ~10–20 times faster than the *p*-nitro compound.⁷⁰⁸ However, solvent effects⁷⁰⁹ are greater: Rates varied over a 300-fold range when the reaction was run in 17 different solvents.⁷¹⁰ An especially good solvent is trifluoroacetic acid, in which the reaction can be carried out at room temperature.⁷¹¹ Most Claisen rearrangements are performed without a catalyst, but AlCl₃ or BF₃ are sometimes used.⁷¹² In this case, it may become a Friedel–Crafts reaction, with the mechanism no longer cyclic,⁷¹³ and ortho, meta, and para products may be obtained.

metals have also been used. Microwave irradiation has been used to facilitate this reaction.⁷¹⁵ The reaction has been done using an AlCl_3 complex as an ionic liquid,⁷¹⁶ and solid-phase Fischer-indole syntheses are known.⁷¹⁷ Aniline derivatives react with α -diazoketones, in the presence of a rhodium catalyst, to give indoles as well.⁷¹⁸ Arylhydrazones are easily prepared by the treatment of aldehydes or ketones with phenylhydrazine (**16-2**) or by aliphatic diazonium coupling (**12-7**). However, it is not necessary to isolate the arylhydrazone. The aldehyde or ketone can be treated with a mixture of phenylhydrazine and the catalyst; this is now common practice. In order to obtain an indole, the aldehyde or ketone must be of the form $\text{RCOCH}_2\text{R}'$ ($\text{R} = \text{alkyl, aryl, or hydrogen}$). Vinyl ethers, such as dihydrofuran, serves as an aldehyde surrogate when treated with phenylhydrazine and a catalytic amount of aqueous sulfuric acid to give an 3-substituted indole.⁷¹⁹

At first glance, the reaction does not seem to be a rearrangement. However, the key step of the mechanism⁷²⁰ is a [3,3]-sigmatropic rearrangement:⁷²¹

There is much evidence for this mechanism, for example, (1) the isolation of **142**,⁷²² (2) the detection of **141** by ^{13}C and ^{15}N NMR,⁷²³ (3) the isolation of side products that could only have come from **140**,⁷²⁴ and (4) ^{15}N labeling experiments that showed

that it was the nitrogen farther from the ring that is eliminated as ammonia.⁷²⁵ The main function of the catalyst seems to be to speed the conversion of **138** to **139**. The reaction can be performed without a catalyst.

There are alternative methods to produce indoles. Acetophenone reacts with 2-chloro nitrobenzene derivatives in the presence of a phenol and a palladium catalyst to give an indole.⁷²⁶

18-35 [2,3]-Sigmatropic Rearrangements

(2/S-3/) → (1/5)-sigma-Migration

Sulfur ylids bearing an allylic group are converted on heating to unsaturated sulfides.⁷²⁷ This is a concerted [2,3]-sigmatropic rearrangement⁷²⁸ and has also been demonstrated for the analogous cases of nitrogen ylids⁷²⁹ and the conjugate bases of allylic ethers (in the last case it is called the [2,3]-Wittig rearrangement).⁷³⁰ It has been argued that the [2,3]-Wittig rearrangement demands severe deformation of the molecule in order to proceed.⁷³¹ The SmI₂ compound has been shown to induce

a [2,3]-Wittig rearrangement.⁷³² The reaction has been extended to certain other systems,⁷³³ even to an all-carbon system.⁷³⁴

Since the reactions involve migration of an allylic group from a sulfur, nitrogen, or oxygen atom to an adjacent negatively charged carbon atom, they are special cases of the Stevens or Wittig rearrangements (**18-21**, **18-22**). However, in this case the migrating group *must* be allylic (in **18-21** and **18-22** other groups can also migrate). Thus, when the migrating group is allylic, there are two possible pathways: (1) the radical-ion or ion-pair mechanisms (**18-21**, **18-22**) and (2) the concerted pericyclic [2,3]-sigmatropic rearrangement. These can easily be told apart, since the latter always involves an allylic shift (as in the Claisen rearrangement), while the former pathway does not.

Of these reactions, the [2,3]-Wittig rearrangement in particular has often been used as a means of transferring chirality. The product of this reaction has potential stereogenic centers at C-3 and C-4 (if $R^5 \neq R^6$), and if the starting ether is optically active because of a stereogenic center at C-1, the product may be optically active as well. Many examples are known in which an optically active ether was converted to a product that was optically active because of chirality at C-3, C-4, or both.⁷³⁵ If a

suitable stereogenic center is present in R^1 (or if a functional group in R^1 can be so converted), then stereocontrol over three contiguous stereogenic centers can be achieved. Stereocontrol of the new double bond (*E* or *Z*) has also been accomplished.

If an OR or SR group is attached to the negative carbon, the reaction becomes a method for the preparation of β,γ -unsaturated aldehydes, because the product is easily hydrolyzed.⁷³⁶

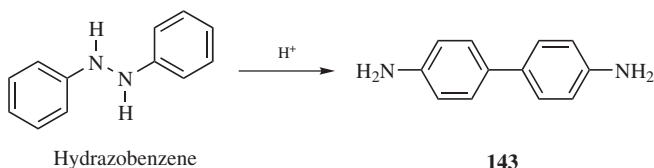

Another [2,3]-sigmatropic rearrangement converts allylic sulfoxides to allylically rearranged alcohols by treatment with a thiophilic reagent, such as trimethyl phosphite.⁷³⁷ This is often called the *Mislow–Evans rearrangement*. In this case, the migration is from sulfur to oxygen. [2,3]-Oxygen-to-sulfur migrations are also known.⁷³⁸ The Sommelet–Hauser rearrangement (**13-31**) is also a [2,3]-sigmatropic rearrangement.

When hydrazobenzene is treated with acids, it rearranges to give ~70% 4,4'-diaminobiphenyl (**143**, benzidine) and ~30% 2,4'-diaminobiphenyl. This reaction is called the *benzidine rearrangement* and is general for *N,N'*-diarylhydrazines.⁷³⁹ Usually, the major product is the 4,4'-diaminobiaryl, but four other products may also be produced. These are the 2,4'-diaminobiaryl, already referred to, the 2,2'-diaminobiaryl, and the *o*- and *p*-arylaminoanilines (called *semidines*). The 2,2'- and *p*-arylaminoaniline compounds are formed less often and in smaller amounts than the other two side products. Usually, the 4,4'-diaminobiaryl predominates, except when one or both para positions of the diarylhydrazine are occupied. However, the 4,4'-diamine may still be produced even if the para positions are occupied. If SO₃H, COOH, or Cl (but not R, Ar, or NR₂) is present in the para position, it may be ejected. With dinaphthylhydrazines, the major products are not the 4,4'-diaminobinaphthyls, but the 2,2' isomers. Another side reaction is disproportionation to ArNH₂ and ArN=NAr. For example, *p,p'*-PhC₆H₄NHNHC₆H₄Ph gives 88% disproportionation products at 25°C.⁷⁴⁰

The mechanism has been exhaustively studied and several mechanisms have been proposed.⁷⁴¹ At one time, it was believed that NHAr broke away from ArNHNHAr and became attached to the para position to give the semidine, which then went on to product. The fact that semidines could be isolated lent this argument support, as did the fact that this would be analogous to the rearrangements considered in Chapter 11 (**11-28–11-32**). However, this theory was killed when it was discovered that semidines could not be converted to benzidines under the reaction conditions. Cleavage into two independent pieces (either ions or radicals) has been ruled out by many types of crossover experiments, which always showed that the two rings of the starting material are in the product; that is, ArNHNHAr' gives no molecules (of any of the five products) containing two Ar groups or two Ar' groups, and mixtures of ArNHNHAr and Ar'NHNHAr' give no molecules containing both Ar and Ar'. An important discovery was the fact that, although the reaction is always first order in substrate, it can be either

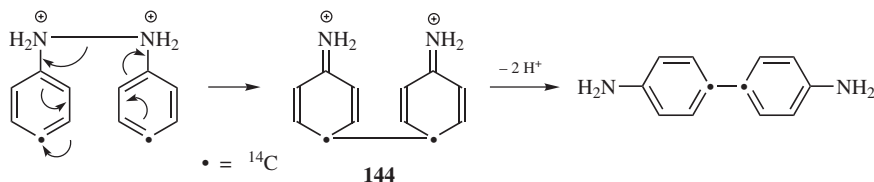

⁷³⁹For reviews, see, in Patai, S. *The Chemistry of the Hydrazo, Azo, and Azoxy Groups*, pt. 2, Wiley, NY, **1975**, the reviews by Cox, R.A.; Buncl, E. pp. 775–807; Koga, G.; Koga, N.; Anselme, J. pp. 914–921; Williams, D.L.H., in Bamford, C.H.; Tipper, C.F.H. *Comprehensive Chemical Kinetics*, Vol. 9, Elsevier, NY, **1973**, Vol. 13, 1972, pp. 437–448; Shine, H.J. *Mech. first⁷⁴² or second⁷⁴³ order in $[H^+]$. With some substrates the reaction is entirely first order in $[H^+]$, while with others it is entirely second order in $[H^+]$, regardless of the acidity. With still other substrates, the reaction is first order in $[H^+]$ at low acidities and second order at higher acidities. With the latter substrates fractional orders can often be observed,⁷⁴⁴ because at intermediate acidities, both processes take place simultaneously. These kinetic results seem to indicate that the actual reacting species can be either the monoprotonated substrate $ArNHNH_2Ar$ or the diprotonated $ArNH_2NH_2Ar$.

Most of the proposed mechanisms⁷⁴⁵ attempted to show how all five products could be produced by variations of a single process. An important breakthrough was the discovery that the two main products are formed in entirely different ways, as shown by isotope-effect studies.⁷⁴⁶ When the reaction was run with hydrazobenzene labeled with ^{15}N at both nitrogen atoms, the isotope effect was 1.022 for formation of **143**, but 1.063 for formation of 2,4'-diaminobiphenyl. This showed that the N–N bond is broken in the rate-determining step in both cases, but the steps themselves are obviously different. When the reaction was run with hydrazobenzene labeled with ^{14}C at a para position, there was an isotope effect of 1.028 for formation of **143**, but essentially no isotope effect (1.001) for formation of 2,4'-diaminobiphenyl. This can only mean that for **143** formation of the new C–C bond *and* breaking of the N–N bond both take place in the rate-determining step; in other words, the mechanism is concerted. The following [5.5]-sigmatropic rearrangement accounts for this:^{745,747}

⁷⁴²Banthorpe, D.V.; Hughes, E.D.; Ingold, C.K. *J. Chem. Soc.* **1962**, 2386, 2402, 2407, 2413, 2418, 2429; Shine, H.J.; Chamness, J.T. *J. Org. Chem.* **1963**, 28, 1232; Banthorpe, D.V.; O'Sullivan, M. *J. Chem. Soc. B* **1968**, 627.

⁷⁴⁵For example, see the "polar-transition-state mechanism:" Banthorpe, D.V.; Hughes, E.D.; Ingold, C.K. *J. Chem. Soc.* **1964**, 2864, and the " π -complex mechanism:" Dewar, M.J.S., in de Mayo, P. *Molecular Rearrangements*, Vol. 1, Wiley, NY, **1963**, pp. 323–344.

⁷⁴⁶Shine, H.J.; Zmuda, H.; Park, K.H.; Kwart, H.; Horgan, A.J.; Collins, C.; Maxwell, B.E. *J. Am. Chem. Soc.* **1981**, 103, 955; Shine, H.J.; Zmuda, H.; Park, K.H.; Kwart, H.; Horgan, A.J.; Brechbiel, M. *J. Am. Chem. Soc.* **1982**, 104, 2501.

⁷⁴⁷This step was also part of the "polar-transition-state mechanism".

The diion **144** was obtained as a stable species in super acid solution at -78°C by treatment of hydrazobenzene with $\text{FSO}_3\text{H}-\text{SO}_2$ (SO_2ClF).⁷⁴⁸ Though the results just given were obtained with hydrazobenzene, which reacts by the diprotonated pathway, monoprotonated substrates have been found to react by the same [5,5]-sigmatropic mechanism.⁷⁴⁹ Some of the other rearrangements in this section are also sigmatropic. Thus, formation of the *p*-semidine takes place by a [1,5]-sigmatropic rearrangement,⁷⁵⁰ and the conversion of 2,2'-hydrazonaphthalene to 2,2'-diamino-1,1'-binaphthyl by a [3,3]-sigmatropic rearrangement.⁷⁵¹

2,4'-Diaminobiphenyl is formed by a completely different mechanism, though the details are not known. There is rate-determining breaking of the N-N bond, but the C-C bond is not formed during this step.⁷⁵² The formation of the *o*-semidine also takes place by a nonconcerted pathway.⁷⁵³ Under certain conditions, benzidine rearrangements have been found to go through radical cations.⁷⁵⁴

C. Other Cyclic Rearrangements

18-37 Metathesis of Alkenes (Alkene or Olefin Metathesis)⁷⁵⁵

Alkene metathesis

When alkenes are treated with certain catalysts they are converted to other alkenes in a reaction in which the alkylidene groups ($\text{R}^1\text{R}^2\text{C}=\text{C}$) have become interchanged by a process schematically illustrated by the equation:

⁷⁵⁵For reviews, see Grubbs, R.H. *Tetrahedron* **2004**, *60*, 7117; Wakamatsu, H.; Blechert, S. *Angew. Chem. Int. Ed.* **2002**, *41*, 2403; Schrock, R.R.; Hoveyda, A.H. *Angew. Chem. Int. Ed.* **2003**, *42*, 4592.

The reaction is called *metathesis* of alkenes or *alkene metathesis* (*olefin metathesis*).⁷⁵⁶ In the example shown above, 2-pentene (either *cis*, *trans*, or a *cis*–*trans* mixture) is converted to a mixture of ~50% 2-pentene, 25% 2-butene, and 25% 3-hexene. The reaction is reversible⁷⁵⁷ and the alkene starting material and products exist in an equilibrium, so the same mixture can be obtained by starting with equimolar quantities of 2-butene and 3-hexene.⁷⁵⁸ In general, the reaction can be applied to a single unsymmetrical alkene, giving a mixture of itself and two other alkenes, or to a mixture of two alkenes, in which case the number of different molecules in the product depends on the symmetry of the reactants. As in the case above, a mixture of $R^1R^2C=CR^1R^2$ and $R^3R^4C=CR^3R^4$ gives rise to only one new alkene ($R^1R^2C=CR^3R^4$), while in the most general case, a mixture of $R^1R^2C=CR^3R^4$ and $R^5R^6C=CR^7R^8$ gives a mixture of 10 alkenes: the original 2 + 8 new ones. In early work, tungsten, molybdenum,⁷⁵⁹ or rhenium complexes were used, and with simple alkenes the proportions of products are generally statistical,⁷⁶⁰ which limited the synthetic utility of the reaction

since the yield of any one product is low. However, in some cases one alkene may be more or less thermodynamically stable than the rest, so that the proportions are not statistical. Furthermore, it may be possible to shift the equilibrium. For example, 2-methyl-1-butene gives rise to ethylene and 3,4-dimethyl-3-hexene. By allowing the gaseous ethylene to escape, the yield of 3,4-dimethyl-3-hexene can be raised to 95%.⁷⁶¹

The development of new catalysts have revolutionized this reaction, making it one of the most important methods available for synthesis. Tailoring the substrate to include two terminal alkenes leads to ethylene as a product, whose escape from the reaction drives the equilibrium to product. Many catalysts, both homogeneous⁷⁶² and heterogeneous,⁷⁶³ have been used for this reaction. Although there are several examples of the former, ruthenium complexes are the most important,⁷⁶⁴ while among the latter are oxides of Mo, W, and Re deposited on alumina or silica gel.⁷⁶⁵ The major breakthrough in these catalysts was the development of catalysts that are relatively air stable. The three most used catalysts are carbene complexes **145**⁷⁶⁶ and **146**⁷⁶⁷ (Grubbs catalysts I and II, respectively), and **147** (the Shrock catalyst).⁷⁶⁸ Catalyst **146** can be generated *in situ* from air stable

can be accomplished with the modern metathesis catalysts. Monosubstituted alkenes react faster than disubstituted alkenes.⁷⁸³ A double metathesis reaction of a diene (also called domino metathesis⁷⁸⁴ or tandem metathesis⁷⁸⁵) with conjugated aldehydes has been reported,⁷⁸⁶ and a triple-metathesis was reported for a dihydropyran with two dihydropyran substituents.⁷⁸⁷ Cross-metathesis of a terminal alkyne and a terminal alkenes (en-yne)⁷⁸⁸ to give a diene has also been reported.⁷⁸⁹ Cross-metathesis of vinylcyclopropanes leads to an alkene with two cyclopropyl substituents.⁷⁹⁰ Vinylcyclopropane-alkyne metathesis reactions have been reported.⁷⁹¹ Cyclic alkenes can be opened, usually with polymerization using metathesis catalysts. Ring-opening metathesis generates dienes from cyclic alkenes.⁷⁹² Allenes undergo a metathesis reaction to give symmetrical Allenes.⁷⁹³ The Grubbs catalyst is compatible with forming cyclic alkenes by ring-closing metathesis followed by treatment with hydrogen to give the saturated cyclic compound.⁷⁹⁴ An interesting variation reacts an α,ω -diene with a cyclic alkene. The combination of ring-opening metathesis and ring-closing cross-metathesis leads to ring expansion to give a macrocyclic nonconjugated diene.⁷⁹⁵

Dienes can react intermolecularly or intramolecularly.⁷⁹⁶ Intramolecular reactions generate rings, usually alkenes or dienes. Alkene metathesis can be

used to form very large rings, including 21-membered lactone rings.⁷⁹⁷ Diynes can also react intramolecularly to give large-ring alkynes.⁷⁹⁸ Metathesis with vinyl-cyclopropyl-alkynes is also known, producing a ring expanded product (see **148**).⁷⁹⁹

The synthetic importance of ring-closing and ring-opening metathesis reactions has led to the development of several new catalysts.⁸⁰⁰ Catalysts have been developed that are compatible with both water and methanol.⁸⁰¹ The reaction is compatible with the presence of other functional groups,⁸⁰² such as other alkene units,⁸⁰³ carbonyl units,⁸⁰⁴ the alkene unit of conjugated esters,⁸⁰⁵ butenolides⁸⁰⁶ and other lactones,⁸⁰⁷ amines,⁸⁰⁸ amides,⁸⁰⁹ sulfones,⁸¹⁰ phosphine oxides,⁸¹¹ sulfonate esters,⁸¹² and sulfonamides⁸¹³

(see **149**).⁸¹⁴ Ether groups,⁸¹⁵ including vinyl ethers,⁸¹⁶ vinyl halides,⁸¹⁷ vinyl silanes,⁸¹⁸ vinyl sulfones,⁸¹⁹ allylic ethers,⁸²⁰ and thioethers⁸²¹ are also compatible. Asymmetric ring-closing metathesis reactions have been reported.⁸²² Asymmetric ring-opening metathesis has also been reported.⁸²³

Two cyclic alkenes react to give dimeric dienes,⁸²⁴ for example,

However, the products can then react with additional monomers and with each other, so that polymers are generally produced, and the cyclic dienes are obtained only in low yield. The reaction between a cyclic and a linear alkene can give an ring-opened diene:⁸²⁵

Alkenes containing functional groups⁸²⁶ do not give the reaction with most of the common catalysts, but some success has been reported with $\text{WCl}_6\text{-SnMe}_4$ ⁸²⁷ and with certain other catalysts.

The reaction has also been applied to internal triple bonds:⁸²⁸

but it has not been successful for terminal triple bonds,⁸²⁹ although as noted above, molecules with a terminal alkene and a terminal alkyne react quite well. Ring-closing metathesis of alkene-alkynes leads to a cyclic alkene with a pendant vinyl unit (a diene).⁸³⁰ Intramolecular reactions of a double bond with a triple bond are known⁸³¹ and a tetracyclic tetraene has been prepared from a poly-yne-diene.⁸³²

The generally accepted mechanism is a chain mechanism,⁸³³ involving the intervention of a metal-carbene complex (**150** and **151**)⁸³⁴ and a four-membered ring

containing a metal⁸³⁵ (**152–155**).⁸³⁶ In the cross-metathesis reaction shown as an example, $R_2C=CR_2$ reacts with $R^1_2C=CR^1_2$ in the presence of a metal catalyst, M. Initial reaction with the catalyst leads to the two expected metal carbenes, **150** and **151**. Metal carbene **151** can react with both alkenes to form metallocyclobutanes **152** and **153**. Each of these intermediates loses the metal to form the alkenes, the product of metathesis $R_2C=CR_2$ and the one of the original alkenes. In a likewise manner, **150** reacts with each alkene to form metallocyclobutanes **154** and **155**, which decomposes to $R_2C=CR_2$ and the metathesis product.

18-38 Metal-Ion-Catalyzed σ -Bond Rearrangements

Many highly strained cage molecules undergo rearrangement when treated with metallic ions, such as Ag^+ , Rh(I) , or Pd(II) .⁸³⁷ The bond rearrangements observed can be formally classified into two main types: (1) [2+2]-ring

openings of cyclobutanes and (2) conversion of a bicyclo[2.2.0] system to a bicyclopropyl system. The molecule cubane supplies an example of each type (see above). Treatment with Rh(I) complexes converts cubane to tricyclo[4.2.0.0^{2,5}]octa-3,7-diene (**156**),⁸³⁸ an example of type 1, while Ag^+ or Pd(II) causes the second type of reaction, producing cuneane.⁸³⁹ Other examples are

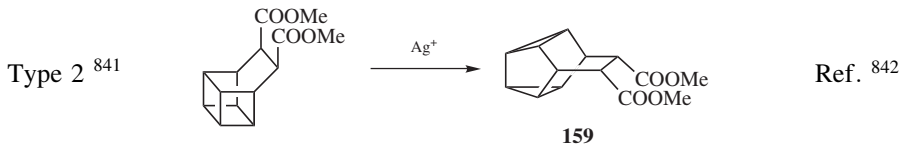

⁸³⁷For reviews, see Halpern, J., in Wender, I.; Pino, P. *Organic Syntheses via Metal Carbonyls*, Vol. 2, Wiley, NY, **1977**, pp. 705–721; Bishop III, K.C. *Chem. 159 is the 9,10-dicarbomethoxy derivative of *snoutane* (pentacyclo[3.3.2.0^{2,4}.0^{3,7}.0^{6,8}]decane).

The mechanisms of these reactions are not completely understood, although relief of strain undoubtedly supplies the driving force. The reactions are thermally forbidden by the orbital-symmetry rules, and the role of the catalyst is to provide low-energy pathways so that the reactions can take place. The type 1 reactions are the reverse of the catalyzed [2 + 2] ring closures discussed at **15-63**. The following mechanism, in which Ag^+ attacks one of the edge bonds, has been suggested for the conversion of **157** to **158**.⁸⁴³

Simpler bicyclobutanes can also be converted to dienes, but in this case the products usually result from cleavage of the central bond and one of the edge bonds.⁸⁴⁴ For example, treatment of **160** with AgBF_4 ,⁸⁴⁵

⁸⁴¹The starting compound here is a derivative of basketane, or 1,8-bishomocubane. For a review of homo-, bishomo-, and trishomocubanes, see Marchand, A.P. *Chem. Rev.* **1989**, 89, 1011.

⁸⁴²See, for example, Furstoss, R.; Lehn, J.M. *Bull. Soc. Chim. Fr.* **1966**, 2497; Dauben, W.G.; Kielbania Jr., A.J. *J. Am. Chem. Soc.* **1971**, 93, 7345; Paquette, L.A.; Beckley, R.S.; Farnham, W.B. *J. Am. Chem. Soc.* **1975**, 97, 1089.

⁸⁴⁴Compound **157** can also be cleaved in this manner, giving a 3-methylenecyclohexene. See, for example, Dauben, W.G.; Kielbania Jr., A.J. *J. Am. Chem. Soc.* **1972**, 94, 3669; Gassman, P.G.; Reitz, R.R. *J. Am. Chem. Soc.* **1973**, 95, 3057; Paquette, L.A.; Zon, G. *J. Am. Chem. Soc.* **1974**, 96, 203, 224.

⁸⁴⁵Paquette, L.A.; Henzel, R.P.; Wilson, S.E. *J. Am. Chem. Soc.* **1971**, 93, 2335.

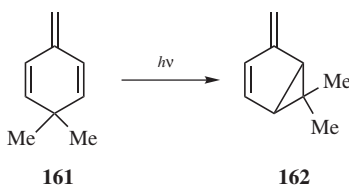

or $[(\pi\text{-allyl})\text{PdCl}]_2$ ⁸⁴⁶ gives a mixture of the two dienes shown, resulting from a formal cleavage of the C₁–C₃ and C₁–C₂ bonds (note that a hydride shift has taken place). Dienes can also be converted to bicyclobutanes under photochemical conditions.⁸⁴⁷

18-39 The Di- π -methane and Related Rearrangements

Di- π -methane rearrangement

1,4-Dienes carrying alkyl or aryl substituents on C-3⁸⁴⁸ can be photochemically rearranged to vinylcyclopropanes in a reaction called the *di- π -methane rearrangement*.⁸⁴⁹ An example is conversion of **161** to **162**.⁸⁵⁰ For most

1,4-dienes it is only the singlet excited states that give the reaction; triplet states generally take other pathways.⁸⁵¹ For unsymmetrical dienes, the reaction is regioselective. For example, **163** gave **164**, not **165**:⁸⁵²

⁸⁴⁶Gassman, P.G.; Meyer, R.G.; Williams, F.J. *Chem. Commun.* **1971**, 842.

⁸⁴⁷Garavelli, M.; Frabboni, B.; Fato, M.; Celani, P.; Bernardi, F.; Robb, M.A.; Olivucci, M. *J. Am. Chem. Soc.* **1999**, *121*, 1537.

⁸⁴⁹For reviews, see Zimmerman, H.E. *Org. Photochem.* **1991**, *11*, 1; Zimmerman, H.E., in de Mayo, P. *Rearrangements in Ground and Excited States*, Vol. 3, Academic Press, NY, **1980**, pp. 131–166; Hixson, S.S.; Mariano, P.S.; Zimmerman, H.E. *Chem. Rev.* **1973**, *73*, 531. See also: Roth, W.R.; Wildt, H.; Schlemenat, A. *Eur. J. Org. Chem.* **2001**, 4081.

⁸⁵⁰Zimmerman, H.E.; Hackett, P.; Juers, D.F.; McCall, J.M.; Schröder, B. *J. Am. Chem. Soc.* **1971**, *93*, 3653.

⁸⁵¹However, some substrates, generally rigid bicyclic molecules, (e.g., barrelene, p. 152, which is converted to semi-bullvalene) give the di- π -methane rearrangement only from triplet states.

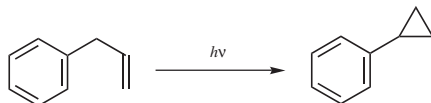

⁸⁵²Zimmerman, H.E.; Baum, A.A. *J. Am. Chem. Soc.* **1971**, *93*, 3646. See also, Zimmerman, H.E.; Welter, T.R. *J. Am. Chem. Soc.* **1978**, *100*, 4131; Alexander, D.W.; Pratt, A.C.; Rowley, D.H.; Tipping, A.E. *J. Chem. Soc., Chem. Commun.* **1978**, 101; Paquette, L.A.; Bay, E.; Ku, A.Y.; Rondan, N.G.; Houk, K.N. *J. Org. Chem.* **1982**, *47*, 422.

The mechanism can be described by the diradical pathway given⁸⁵³ (the C-3 substituents act to stabilize the radical), though the species shown are not necessarily intermediates, but may be transition states. It has been shown, for the case of certain substituted substrates, that configuration is retained at C-1 and C-5 and inverted at C-3.⁸⁵⁴

The reaction has been extended to allylic benzenes⁸⁵⁵ (in this case C-3 substituents are not required), to β,γ -unsaturated ketones⁸⁵⁶ (the latter reaction, which is called the *oxa-di- π -methane rearrangement*,⁸⁵⁷ generally occurs only from the triplet state), to β,γ -unsaturated imines,⁸⁵⁸ and to triple-bond systems.⁸⁵⁹

When photolyzed, 2,5-cyclohexadienones can undergo a number of different reactions, one of which is formally the same as the di- π -methane rearrangement.⁸⁶⁰ In this reaction, photolysis of the substrate **166** gives the bicyclo[3.1.0]hexenone (**171**). Although the reaction is formally the same (note the conversion of **161** to **162**

above), the mechanism is different from that of the di- π -methane rearrangement, because irradiation of a ketone can cause an $n \rightarrow \pi^*$ transition, which is of course not possible for a diene lacking a carbonyl group. The mechanism⁸⁶¹ in this case has been formulated as proceeding through the excited triplet states **168** and **169**. In step 1, the molecule undergoes an $n \rightarrow \pi^*$ excitation to the singlet species **167**, which cross to the triplet **168**. Step 3 is a rearrangement from one excited state to another. Step 4 is a $\pi^* \rightarrow n$ electron demotion (an intersystem crossing from $T_1 \rightarrow S_0$, see p. 339). The conversion of **170** to **171** consists of two 1,2 alkyl migrations (a one-step process would be a 1,3-migration of alkyl to a carbocation center, see p. \$\$\$): The old C_6-C_5 bond becomes the new C_6-C_4 bond and the old C_6-C_1 bond becomes the new C_6-C_5 bond.⁸⁶²

2,4-Cyclohexadienones also undergo photochemical rearrangements, but the products are different, generally involving ring opening.⁸⁶³

18-40 The Hofmann-Löffler and Related Reactions

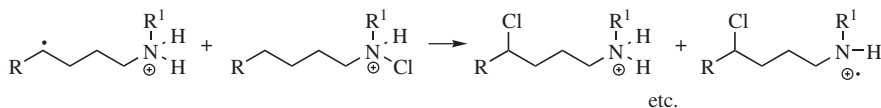

A common feature of the reactions in this section⁸⁶⁴ is that they serve to introduce functionality at a position remote from functional groups already present. As such, they have proved very useful in synthesizing many compounds, especially in the steroid field (see also, **19-2** and **19-17**). When *N*-haloamines in which one alkyl group has a hydrogen in the 4 or 5 position are heated with sulfuric acid, pyrrolidines, or piperidines are formed, in a reaction known as the *Hofmann-Löffler reaction* (also called the *Hofmann-Löffler-Freytag reaction*).⁸⁶⁵ The *R'* group is normally alkyl, but the reaction has been extended to *R'* = H by the use of concentrated sulfuric acid solution and ferrous salts.⁸⁶⁶ The first step of the reaction is a rearrangement, with the halogen migrating from the nitrogen to the 4 or 5 position of the alkyl group. It is possible to isolate the resulting haloamine salt, but usually this is not done, and the second step, the ring closure (**10-31**), takes place. Though the reaction is most often induced by heat, this is not necessary, and irradiation and chemical initiators (e.g., peroxides) have been used instead. The mechanism is of a free-radical type, with the main step involving an internal hydrogen abstraction.⁸⁶⁷

Initiation

Propagation

A similar reaction has been carried out on *N*-halo amides, which give γ -lactones:⁸⁶⁸

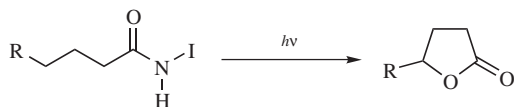

⁸⁶⁴For a review of the reactions in this section, see Carruthers, W. *Some Modern Methods of Organic Synthesis* 3rd ed.; Cambridge University Press: Cambridge, **1986**, pp. 263–279.

Am. Chem. Soc.* **1966**, *88*, 3051. For a review of *N*-halo amide rearrangements, see Neale, R.S. *Synthesis* **1971**, 1.

Another related reaction is the *Barton reaction*,⁸⁶⁹ by which a methyl group in the δ position to an OH group can be oxidized to a CHO group. The alcohol is first converted to the nitrite ester. Photolysis of the nitrite results in conversion of the nitrite group to the OH group and nitrosation of the methyl group. Hydrolysis of the oxime tautomer gives the aldehyde, for example,⁸⁷⁰

This reaction takes place only when the methyl group is in a favorable steric position.⁸⁷¹ The mechanism is similar to that of the Hofmann-Löffler reaction.⁸⁷²

⁸⁶⁹For reviews, see Hesse, R.H. *Adv. Free-Radical Chem.* **1969**, 3, 83; Barton, D.H.R. *Pure Appl. Chem.* **1968**, 16, 1.

This is one of the few known methods for effecting substitution at an angular methyl group. Not only CH_3 groups, but also alkyl groups of the form RCH_2 and R_2CH can give the Barton reaction if the geometry of the system is favorable. An RCH_2 group is converted to the oxime $\text{R}(\text{C}=\text{NOH})$ (which is hydrolyzable to a ketone) or to a nitroso dimer, while an R_2CH group gives a nitroso compound $\text{R}_2\text{C}(\text{NO})$. With very few exceptions, the only carbons that become nitrosated are those in the position δ to the original OH group, indicating that a six-membered transition state is necessary for the hydrogen abstraction.⁸⁷³

OS III, 159.

D. Noncyclic Rearrangements

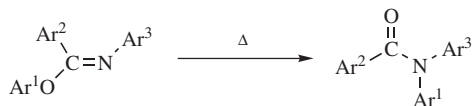

18-41 Hydride Shifts

The above is a typical example of a transannular hydride shift. The 1,2-diol is formed by a normal epoxide hydrolysis reaction (10-7). For a discussion of 1,3 and longer hydride shifts (see p. 1572).

18-42 The Chapman Rearrangement

1/O \rightarrow 3/N-Aryl-migration

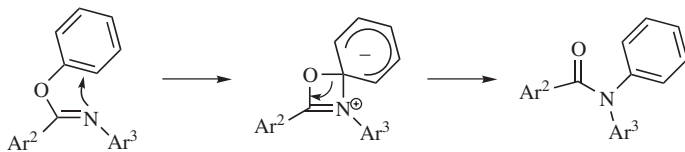

In the *Chapman rearrangement*, *N,N*-diaryl amides are formed when aryl imino esters are heated.⁸⁷⁴ Best yields are obtained in refluxing tetraethylene glycol dimethyl ether (tetraglyme),⁸⁷⁵ although the reaction can also be carried out without any solvent at all. Many groups may be present in the rings, for example, alkyl, halo, OR, CN, and COOR. Aryl migrates best when it contains electron-withdrawing groups. On the other hand, electron-withdrawing groups in Ar^2 or Ar^3 decrease the reactivity. The products can be hydrolyzed to diarylamines, and

⁸⁷⁵Wheeler, O.H.; Roman, F.; Santiago, M.V.; Quiles, F. *Can. J. Chem.* **1969**, *47*, 503.

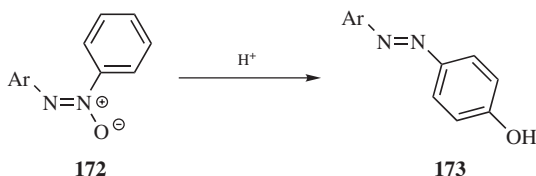

this is a method for preparing these compounds. The mechanism probably involves an intramolecular⁸⁷⁶ aromatic nucleophilic substitution, resulting in a 1,3 oxygen-to-nitrogen shift. Aryl imino esters can be prepared from *N*-aryl amides by reaction with PCl_5 , followed by treatment of the resulting imino chloride with an aroxide ion.⁸⁷⁷

Imino esters with any or all of the three groups being alkyl also rearrange, but they require catalysis by H_2SO_4 or a trace of methyl iodide or methyl sulfate.⁸⁷⁸ The mechanism is different, involving an intermolecular process.⁸⁷⁹ This is also true for derivatives for formamide ($\text{Ar}^2 = \text{H}$).

18-43 The Wallach Rearrangement

The conversion of azoxy compounds, on acid treatment, to *p*-hydroxy azo compounds (or sometimes the *o*-hydroxy isomers⁸⁸⁰) is called the *Wallach rearrangement*.⁸⁸¹ When both para positions are occupied, the *o*-hydroxy product may be

⁸⁷⁶For evidence for the intramolecular character of the reaction, see Wiberg, K.B.; Rowland, B.I. *J. Am. Chem. Soc.* **1955**, *77*, 2205; Wheeler, O.H.; Roman, F.; Rosado, O. *J. Org. Chem.* **1969**, *34*, 966; Kimura, M. *J. Chem. Soc. Perkin Trans. 2* **1987**, 205.

obtained, but ipso substitution at one of the para positions is also possible.⁸⁸² Although the mechanism⁸⁸³ is not completely settled, the following facts are known: (1) The para rearrangement is intermolecular.⁸⁸⁴ (2) When the reaction was carried out with an azoxy compound in which the N–O nitrogen was labeled with ¹⁵N, both nitrogens of the product carried the label equally,⁸⁸⁵ demonstrating that the oxygen did not have a preference for migration to either the near or the far ring. This shows that there is a symmetrical intermediate. (3) Kinetic studies show that two protons are normally required for the reaction.⁸⁸⁶ The following mechanism,⁸⁸⁷ involving the symmetrical intermediate **175**, has been proposed to explain the facts.⁸⁸⁸

It has proved possible to obtain **174** and **175** as stable species in super acid solutions.⁷⁴⁸ Another mechanism, involving an intermediate with only one positive charge, has been proposed for certain substrates at low acidities.⁸⁸⁹

A photochemical Wallach rearrangement⁸⁹⁰ is also known: The product is the *o*-hydroxy azo compound, the OH group is found in the farther ring, and the rearrangement is intramolecular.⁸⁹¹

(α -hydroxybenzyl)trialkylsilanes (**176**) in the presence of a catalytic amount of base.⁸⁹⁸ Formation of a Si–O bond rather than the Si–C bond drives the rearrangement, which is believed to proceed via formation of **177**, and does proceed with inversion of configuration at carbon and retention of configuration at silicon.⁸⁹⁹ A reverse Brook rearrangement is also known.⁹⁰⁰ The reaction has been extended to other systems. A homo-Brook rearrangement has also been reported.⁹⁰¹ Another variation is the aza-Brook rearrangement of α -silylallyl)amines.⁹⁰² The Brook rearrangement has been used in synthesis involving silyl dithianes.⁹⁰³ A Brook rearrangement mediated [6 + 2]-annulation has been used for the construction of eight-membered carbocycles.⁹⁰⁴

The Brook rearrangement has been used in two important synthetic applications, a multicomponent coupling protocol initiated by a Brook rearrangement involving silyl dithianes as mentioned, and anion relay chemistry (ARC) involving a Brook rearrangement. An example of the former is the conversion of the 2-silyl dithiane **178** to the anion with *tert*-butyllithium followed by ring opening of an epoxide to give **179**.⁹⁰⁵ Treatment with HMPA triggers a solvent-controlled Brook rearrangement that gives a new dithiane anion (**180**), which then reacts with a different epoxide to give the final product, **181**. An example of the anion relay chemistry treats dithiane (**182**) with *n*-butyllithium, and then **183** to give **184**.⁹⁰⁶ Subsequent treatment with a variety of electrophiles, such as allyl bromide, in HMPA, leads to **185** via a Brook rearrangement, and then alkylation of the resultant dithian anion. This reaction can be initiated by nucleophiles other

than dithiane anion. Organocuprates can be used, and the anion stabilizing group can be a nitrile.⁹⁰⁷

⁹⁰⁷Private communication, Professor Amos B. Smith III, University Pennsylvania.

Oxidations and Reductions

First, we must examine what we mean when we speak of oxidation and reduction. Inorganic chemists define oxidation in two ways: loss of electrons and increase in oxidation number. In organic chemistry, these definitions, while still technically correct, are not easy to apply. While electrons are directly transferred in some organic oxidations and reductions, the mechanisms of most of these reactions do not involve a direct electron transfer. As for oxidation number, while this is easy to apply in some cases, (e.g., the oxidation number of carbon in CH_4 is -4), in most cases attempts to apply the concept lead to fractional values or to apparent absurdities. Thus carbon in propane has an oxidation number of -2.67 and in butane of -2.5 , although organic chemists seldom think of these two compounds as being in different oxidation states. An improvement could be made by assigning different oxidation states to different carbon atoms in a molecule, depending on what is bonded to them (e.g., the two carbons in acetic acid are obviously in different oxidation states), but for this a whole set of arbitrary assumptions would be required, since the oxidation number of an atom in a molecule is assigned on the basis of the oxidation numbers of the atoms attached to it. There would seem little to be gained by such a procedure. The practice in organic chemistry has been to set up a series of functional groups, in a qualitative way, arranged in order of increasing oxidation state, and then to define oxidation as *the conversion of a functional group in a molecule from one category to a higher one*. Reduction is the opposite. For the simple functional groups this series is shown in Table 19.1.¹ Note that this classification applies only to a single carbon atom or to two adjacent carbon atoms. Thus 1,3-dichloropropane is in the same oxidation state as chloromethane, but 1,2-dichloropropane is in a higher one. Obviously, such distinctions are somewhat arbitrary, and if we attempt to carry them too far, we will find ourselves painted into a corner. Nevertheless, the basic idea has served organic chemistry well. Note that

¹For more extensive tables, with subclassifications, see Soloveichik, S.; Krakauer, H. *J. Chem. Educ.* **1966**, *43*, 532.

TABLE 19.1. Categories of Simple Functional Groups Arranged According to Oxidation State^a

	RNH ₂			
	and so on			
			and so on	
		and so on		
	Approximate Oxidation Number			
-4	-2	0	+2	+4

^aOxidation is the conversion of a functional group in a molecule to a higher category; reduction is conversion to a lower one. Conversions within a category are neither oxidations nor reductions. The numbers given at the bottom are only approximations.

conversion of any compound to another in the same category is not an oxidation or a reduction. Most oxidations in organic chemistry involve a gain of oxygen and/or a loss of hydrogen (Lavoisier's original definition of oxidation). The reverse is true for reductions.

Of course, there is no oxidation without a concurrent reduction. However, we classify reactions as oxidations or reductions depending on whether the *organic compound* is oxidized or reduced. In some cases, both the oxidant and reductant are organic; those reactions are treated separately at the end of the chapter.

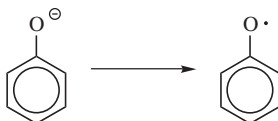

MECHANISMS

Noted that our definition of oxidation has nothing to do with mechanism. Thus the conversion of bromomethane to methanol with KOH (**10-1**) and to methane with LiAlH₄ (**19-53**) have the same S_N2 mechanisms, but one is a reduction (according to our definition) and the other is not. It is impractical to consider the mechanisms

of oxidation and reduction reactions in broad categories in this chapter as we have done for the reactions considered in Chapters 10–18.² The main reason is that the mechanisms are too diverse, and this in turn is because the bond changes are too different. For example, in Chapter 15, most reactions involved the bond change $C=C \rightarrow W-C-C-Y$ yet a relatively few mechanisms covered those reactions. But for oxidations and reductions the bond changes are far more diverse. Another reason is that the mechanism of a given oxidation or reduction reaction can vary greatly with the oxidizing or reducing agent employed. Very often the mechanism has been studied intensively for only one or a few of many possible agents.

Although we do not cover oxidation and reduction mechanisms in the same way as we have covered other mechanisms, it is still possible to list a few broad mechanistic categories. In doing this, we follow the scheme of Wiberg.³

1. *Direct Electron Transfer.*⁴ We have already met some reactions in which the reduction is a direct gain of electrons or the oxidation a direct loss of them. An example is the Birch reduction (15-13), where sodium directly transfers an electron to an aromatic ring. An example from this chapter is found in the bimolecular reduction of ketones (19-76), where again it is a metal that supplies the electrons. This kind of mechanism is found largely in three types of reaction:⁵ (a) the oxidation or reduction of a free radical (oxidation to a positive or reduction to a negative ion), (b) the oxidation of a negative ion or the reduction of a positive ion to a comparatively stable free radical, and (c) electrolytic oxidations or reductions (an example is the Kolbe reaction, 14-29). An important example of (b) is oxidation of amines and phenolate ions:

Chem.* 1982, 18, 79. For a review of multistage electron-transfer mechanisms, see Deuchert, K.; Hünig, S. *Angew. Chem. Int. Ed.* 1978, 17, 875.

⁵Littler, J.S.; Sayce, I.G. *J. Chem. Soc.* 1964, 2545.

These reactions occur easily because of the relative stability of the radicals involved.⁶ The single electron-transfer mechanism (SET), which we have met several times (e.g., p. 264) is an important case.

2. *Hydride Transfer.*⁷ In some reactions, a hydride ion is transferred to or from the substrate. The reduction of epoxides with LiAlH_4 is an example (**19-35**). Another is the Cannizzaro reaction (**19-81**). Reactions in which a carbocation abstracts a hydride ion belong in this category:⁸

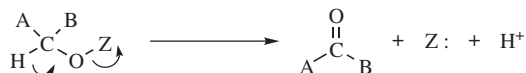

3. *Hydrogen-Atom Transfer.* Many oxidation and reduction reactions are free-radical substitutions and involve the transfer of a hydrogen atom. For example, one of the two main propagation steps of **14-1** involves abstraction of hydrogen:

This is the case for many of the reactions of Chapter 14.

4. *Formation of Ester Intermediates.* A number of oxidations involve the formation of an ester intermediate (usually of an inorganic acid), and then the cleavage of this intermediate:

Z is usually CrO_3H , MnO_3 , or a similar inorganic acid moiety. One example of this mechanism will be seen in **19-23**, where A was an alkyl or aryl group, B was OH, and Z was CrO_3H . Another is the oxidation of a secondary alcohol to a ketone (**19-3**), where A and B are alkyl or aryl groups and Z is also CrO_3H . In the lead tetraacetate oxidation of glycols (**19-7**) the mechanism also follows this pattern, but the positive leaving group is carbon instead of hydrogen. Note that the cleavage shown is an example of an E2 elimination.

5. *Displacement Mechanisms.* In these reactions, the organic substrate uses its electrons to cause displacement on an electrophilic oxidizing agent. One example is the addition of bromine to an alkene (**15-39**).

⁶For a review of the oxidation of phenols, see Mihailović, M.Lj.; Čeković, Z., in Patai, S. *The Chemistry of the Hydroxyl Group*, pt. 1, Wiley, NY, **1971**, pp. 505–592.

⁷For a review, see Watt, C.I.F. *Adv. Phys. Org. Chem.* **1988**, *24*, 57.

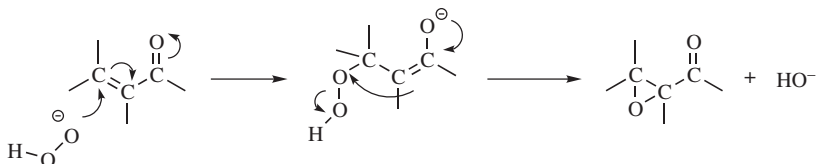

⁸For a review of these reactions, see Nenitzescu, C.D., in Olah, G.A.; Schleyer, P.V.R. *Carbonium Ions*, Vol. 2, Wiley, NY, **1970**, pp. 463–520.

An example from this chapter is found in **19-29**:

- 6. Addition–Elimination Mechanisms.** In the reaction between α,β -unsaturated ketones and alkaline peroxide (**15-50**), the oxidizing agent adds to the substrate and then part of it is lost:

In this case, the oxygen of the oxidizing agent is in oxidation state -1 and the hydroxide ion departs with its oxygen in the -2 state, so it is reduced and the substrate oxidized. There are several reactions that follow this pattern of addition of an oxidizing agent and the loss of part of the agent, usually in a different oxidation state. Another example is the oxidation of ketones with SeO_2 (**19-17**). This reaction is also an example of category 4, since it involves formation and E2 cleavage of an ester. This example shows that these six categories are not mutually exclusive.

REACTIONS

In this chapter, the reactions are classified by the type of bond change occurring to the organic substrate, in conformity with our practice in the other chapters.⁹ This means that there is no discussion in any one place of the use of a particular oxidizing or reducing agent, for example, acid dichromate or LiAlH_4 (except for a discussion of selectivity of reducing agents, p. 1787). Some oxidizing or reducing agents are fairly specific in their action, attacking only one or a few types of substrate.

⁹For a table of oxidation and reduction reactions, and the oxidizing and reducing agents for each, see Hudlický, M. *J. Chem. Educ.* **1977**, *54*, 100.

Others, like acid dichromate, permanganate, LiAlH_4 , and catalytic hydrogenation, are much more versatile.^{10,9,11}

OXIDATIONS^{11,2}

In some cases, oxidations have been placed in another chapter. The oxidation of an alkene to a diol (**15-48**), and aromatic compound to a diol (**15-49**), or oxidation to an epoxide (**15-50**) are placed in Chapter 15, for consistency with the concept of addition to a π -bond. Diamination of an alkene (**15-53**) and formation of aziridines (**15-54**) are in Chapter 15 for the same reason. Most other oxidations have been placed here. The reactions in this section are classified into groups depending on

the type of bond change involved. These groups are (A) eliminations of hydrogen, (B) oxidations involving cleavage of carbon-carbon bonds, (C) reactions involving replacement of hydrogen by oxygen, (D) reactions in which oxygen is added to the substrate, and (E) oxidative coupling.

A. Eliminations of Hydrogen

19-1 Aromatization of Six-Membered Rings

Hexahydro-terelimination

Six-membered alicyclic rings can be aromatized in a number of ways.¹² Aromatization is accomplished most easily if there are already one or two double bonds in the ring or if the ring is fused to an aromatic ring. The reaction can also be applied to heterocyclic five- and six-membered rings. Many groups may be present on the ring without interference, and even *gem*-dialkyl substitution does not always prevent the reaction: In such cases, one alkyl group often migrates or is eliminated. However, more drastic conditions are usually required for this. In some cases OH and COOH groups are lost from the ring. Cyclic ketones are converted to phenols. Seven-membered and larger rings are often isomerized to six-membered aromatic rings, although this is not the case for partially hydrogenated azulene systems (which are frequently found in Nature); these are converted to azulenes.

There are three types of reagents most frequently used to effect aromatization.

1. Hydrogenation catalysts,¹³ such as platinum, palladium,¹⁴ and nickel. In this case, the reaction is the reverse of double-bond hydrogenation (**15-11** and **15-15**), and presumably the mechanism is also the reverse, although not much is known.¹⁵ Cyclohexene has been detected as an intermediate in the conversion of cyclohexane to benzene, using Pt.¹⁶ The substrate is heated with the catalyst at $\sim 300\text{--}350^\circ\text{C}$. The reactions can often be carried out under milder

conditions if a hydrogen acceptor, such as maleic acid, cyclohexene, or benzene, is present to remove hydrogen as it is formed. The acceptor is reduced to the saturated compound. Other transition metals can be used, including $\text{TiCl}_4\text{-NEt}_3$.¹⁷ It has been reported that dehydrogenation of 1-methylcyclohexene-1-¹³C over an alumina catalyst gave toluene with the label partially scrambled throughout the aromatic ring.¹⁸ For polycyclic systems, heating with oxygen on activated carbon generates the aromatic compound, as in the conversion of dihydroanthracene to anthracene.¹⁹

2. The elements sulfur and selenium, which combine with the hydrogen evolved to give, respectively, H_2S and H_2Se . Little is known about this mechanism either.²⁰
3. Quinones,²¹ which become reduced to the corresponding hydroquinones. Two important quinones often used for aromatizations are chloranil (2,3,5,6-tetrachloro-1,4-benzoquinone) and DDQ (2,3-dichloro-5,6-dicyano-1,4-benzoquinone).²² The latter is more reactive and can be used in cases where the substrate is difficult to dehydrogenate. It is likely that the mechanism involves a transfer of hydride to the quinone oxygen, followed by the transfer of a proton to the phenolate ion:^{23,21}

Among other reagents²⁴ that have been used for aromatization of six-membered rings are atmospheric oxygen, MnO_2 ,²⁵ $\text{KMnO}_4\text{-Al}_2\text{O}_3$,²⁶ SeO_2 , various strong bases,²⁷

chromic acid,²⁸ H₂SO₄ and a ruthenium catalyst,²⁹ and SeO₂ on P₂O₅/Me₃SiOSiMe₃.³⁰ The last-mentioned reagent also dehydrogenates cyclopentanes to cyclopentadienes. In some instances, the hydrogen is not released as H₂ or transferred to an external oxidizing agent, but instead serves to reduce another molecule of substrate. This is a disproportionation reaction and can be illustrated by the conversion of cyclohexene to cyclohexane and benzene. Quinones react with allylic silanes and a Bi(OTf)₃ catalyst to give 2-allyl hydroquinone.³¹ Similar reaction with acetic anhydride rather than an allylic silane leads to a 2-acetoxy hydroquinone.³²

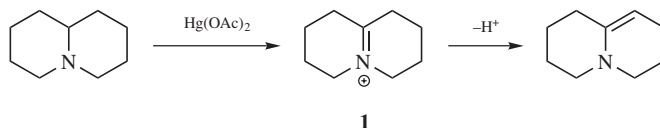

Heteroatom rings, as found in quinoline derivatives, for example, can be generated from amino-ketones with [hydroxy(tosyloxy)iodo]benzene and perchloric acid³³ or with NaHSO₄–Na₂Cr₂O₇ on wet silica.³⁴ Dihydropyridines are converted to pyridines with NaNO₂–oxalic acid and wet silica³⁵ BaMnO₄,³⁶ FeCl₃–acetic acid,³⁷ Mg(HSO₄)₂–NaNO₂,³⁸ NO⁺-18-crown-6-H(NO₃)₂⁻,³⁹ or with nicotinium dichromate.⁴⁰ Cyclic imines are converted to pyridine derivatives with NCS, and then excess sodium methoxide.⁴¹

Note that hydrogenolysis of cyclohexane leads to *n*-hexane with hydrogen and an iridium catalyst.⁴²

Dehydrogenation of an aliphatic compound to give a double bond in a specific location is not usually a feasible process, although industrially mixtures of alkenes are obtained in this way from mixtures of alkanes (generally by heating with chromia–alumina catalysts). There are, however, some notable exceptions. Heating cyclooctane with an iridium catalyst leads to cyclooctene.⁴³ Treating alkenes that have an allylic hydrogen with CrCl_2 converts them to allenes.⁴⁴ It is not surprising, however, that most of the exceptions generally involve cases where the new double bond can be in conjugation with a double bond or with an unshared pair of electrons already present.⁴⁵ One example is the synthesis developed by Leonard and co-workers,⁴⁶ in which tertiary amines give enamines (**10-69**) when treated with mercuric acetate⁴⁷ (see the example above). In this case the initial product is the iminium ion **1** which loses a proton to give the enamine. In another example, the oxidizing agent SeO_2 can in certain cases convert a carbonyl compound to an α,β -unsaturated carbonyl compound by removing H_2 ⁴⁸ (though this reagent more often gives **19-17**). This reaction has been most often applied in the steroid series, an example being formation of **2** from **3**.⁴⁹ In a similar manner, Hünig's base, diisopropylethylamine, was converted to the enamine *N,N*-diisopropyl-*N*-vinylamine by heating with an iridium catalyst.⁵⁰

Similarly, SeO_2 has been used to dehydrogenate 1,4-diketones⁵¹ ($\text{RCOCH}_2\text{CH}_2\text{COR} \rightarrow \text{RCOCH}=\text{CHCOR}$) and 1,2-diaryllkanes ($\text{ArCH}_2\text{CH}_2\text{Ar} \rightarrow \text{ArCH}=\text{CHAr}$). These conversions can also be carried out by certain quinones, most notably DDQ (see **19-1**).²² Ketones have been converted to conjugated ketones with

Ph(S=O)OMe and KH,⁵² and also with (pyridyl)S(=O)OMe/KH, and then CuSO₄.⁵³ Silyl enol ethers also give the conjugated ketone upon treatment with ceric ammonium nitrate in DMF⁵⁴ or with Pd(OAc)₂/NaOAc/O₂.⁵⁵ Simple aldehydes and ketones have been dehydrogenated (e.g., cyclopentanone → cyclopentenone) by PdCl₂,⁵⁶ by FeCl₃,⁵⁷ and by benzeneseleninic anhydride⁵⁸ (this reagent also dehydrogenates lactones in a similar manner), among other reagents.

In an indirect method of achieving this conversion, the silyl enol ether of a simple ketone is treated with DDQ⁵⁹ or with triphenylmethyl cation⁶⁰ (for another indirect method, see 17-12). Simple linear alkanes have been converted to alkenes by treatment with certain transition-metal compounds.⁶¹

An entirely different approach to specific dehydrogenation has been reported by R. Breslow⁶² and by J.E. Baldwin.⁶³ By means of this approach it was possible, for example, to convert 3 α -cholestanol (**4**) to 5 α -cholest-14-en-3 α -ol (**5**), thus introducing a double bond at a specific site remote from any functional group.⁶⁴ This was

accomplished by conversion of **4** to the ester **6**, followed by irradiation of **6**, which gave 55% **8**, which was then

hydrolyzed to **5**. The radiation excites the benzophenone portion of **6** (p. \$\$\$), which then abstracts hydrogen from the 14 position to give the diradical **7**, which undergoes another internal abstraction to give **8**. In other cases, diradicals like **7** can close to a macrocyclic lactone (**19-17**). In an alternate approach,⁶⁵ a 9(11) double bond was introduced into a steroid nucleus by reaction of the *m*-iodo ester **9** with $PhICl_2$ and uv light, which results in hydrogen being abstracted regioselectively from the 9 position, resulting in chlorination at that position. Dehydrohalogenation of **10** gives the 9(11)-unsaturated steroid **11**. In contrast, use of the para isomer of **7** results in chlorination at the 14 position and loss of HCl gives the 14-unsaturated steroid. These reactions are among the very few ways to introduce functionality at a specific site remote from any functional group (see also, **19-17**).

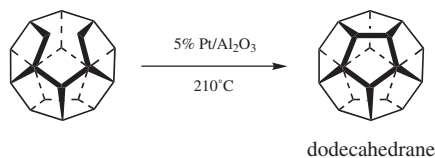

Certain 1,2-diarylalkenes $ArCH=CHAr'$ have been converted to the corresponding alkynes $ArC\equiv CAr'$ by treatment with *t*-BuOK in DMF.⁶⁶ Dihydroindoles are converted to indoles with *N,N,N'*-trichloro-1,3,5-triazin-2,4,6-trione and DBU.⁶⁷

For a lengthy list of reagents, with references, see Larock, R.C. *Comprehensive Organic Transformations*, 2nd ed., Wiley-VCH, NY, **1999**, pp. 1234–1250.

⁷⁰For thorough discussions, see Lee, D.G., in Augustine, R.L.; Trecker, D.J. *Oxidation*, Vol. 2, Marcel Dekker, NY, **1971**, pp. 56–81; and (with respect to chromium and manganese reagents) House, H.O. *Modern Synthetic Reactions*, 2nd ed., W.A. Benjamin, NY, **1972**, pp. 257–273.

⁷¹Various forms of H₂CrO₄ and of CrO₃ are used for this reaction. For a review, see Cainelli, G.; Cardillo, G. *Chromium Oxidations in Organic Chemistry*, Open Court Publishers Co., La Salle, IL, **1981**, pp. 118–216. For discussions, see Fieser, L.F.; Fieser, M. *Reagents for Organic Synthesis*, Vol. 1, Wiley, NY, **1967**, pp. 142–147, 1059–1064, and subsequent volumes in this series.

other strong oxidizing agents (KMnO_4 ,⁷² ruthenium tetroxide,⁷³ etc.) have also been employed. A solution of chromic acid and sulfuric acid in water is known as the *Jones reagent*.⁷⁴ When secondary alcohols are dissolved in acetone, titration with the Jones reagent oxidizes them to ketones rapidly and in high yield without disturbing any double or triple bonds that may be present (see **19-10**) and without epimerizing an adjacent stereogenic center.⁷⁵ The Jones reagent can also oxidize primary allylic alcohols to the corresponding aldehydes,⁷⁶ although overoxidation to the carboxylic acid is a problem. Oxidative cleavage of primary alcohols has been observed in the presence of molecular sieve 3 Å.⁷⁷ Indeed, for the oxidation of allylic alcohols three other Cr(VI) reagents are commonly used,⁷⁸ dipyridine Cr(VI) oxide (*Collins' reagent*),⁷⁹ pyridinium chlorochromate (PCC),⁸⁰ and pyridinium dichromate (PDC).⁸¹ The PCC is somewhat acidic, and acid-catalyzed rearrangements have been observed.⁸² A variety of amines and diamines have been converted to tetraalkylammonium halochromates or dichromates. Examples include *N*-benzyl 1,4-diazabicyclo[2.2.2]octane ammonium dichromate with microwave irradiation,⁸³ γ -picolinium chlorochromate,⁸⁴ and quinolinium

fluorochromate.⁸⁵ benzyltriphenylphosphonium chlorochromate has been used in a similar manner.⁸⁶ Ammonium dichromate with HIO_3 on wet silica gel⁸⁷ or ammonium chlorochromate on Montmorillonite K10⁸⁸ have also been used. The MnO_2 ⁸⁹ reagent is also a fairly specific reagent for oxidation of allylic and benzylic OH groups in preference to aliphatic substrates. For acid-sensitive compounds, CrO_3 in HMPA⁹⁰ or trimethylsilyl chromates⁹¹ can be used. Benzylic alcohols are oxidized to aldehydes with BaCr_2O_7 in acetonitrile.⁹² Both CrO_3 ⁹³ and MnO_2 ⁹⁴ have been used to oxidize primary and benzylic alcohols, respectively, under solvent-free conditions. A catalytic mixture of *N*-hydroxyphthalimide, $\text{Co}(\text{OAc})_2$ and mcpba oxidizes secondary alcohols to ketones.⁹⁵ Chromium trioxide with aqueous *tert*-butylhydroperoxide oxidizes benzylic alcohols with microwave irradiation.⁹⁶ Oxidizing agents have been supported on a polymer,⁹⁷ including chromic acid⁹⁸ and permanganate,⁹⁹ as well as poly[vinyl(pyridinium fluorochromate)].¹⁰⁰ Microwave induced oxidation of benzylic alcohols was reported using zeolite-supported ferric nitrate.¹⁰¹ Microwave irradiation of CrO_3 with various co-reagents oxidizes alcohols.¹⁰² Phase-transfer catalysis has also been used with permanganate,¹⁰³ chromic acid,¹⁰⁴ and

ruthenium tetroxide.¹⁰⁵ Phase-transfer catalysis is particularly useful because the oxidizing agents are insoluble in most organic solvents, while the substrates are generally insoluble in water (see p. 508). Ultrasound has been used for KMnO_4 oxidations.¹⁰⁶ A catalytic amount of $\text{Cr}(\text{acac})_3$ in conjunction with H_5IO_5 oxidizes benzylic alcohols to aldehydes.¹⁰⁷

Most of these oxidizing agents have also been used to convert primary alcohols to aldehydes, but precautions must be taken that the aldehyde is not further oxidized to the carboxylic acid (**19-22**).¹⁰⁸ When powerful oxidants, such as chromic acid, are used, one way to halt oxidation is by distillation of the aldehyde as it is formed. The following are among the oxidizing agents that have been used to convert at least some primary alcohols to aldehydes:¹⁰⁹ Collins' reagent, pyridinium chlorochromate and pyridinium dichromate, pyridinium dichromate, $\text{Na}_2\text{Cr}_2\text{O}_7$ in water,¹¹⁰ $\text{K}_2\text{Cr}_2\text{O}_7$ in DMF at 100°C ,¹¹¹ CrO_3 on silica gel,¹¹² wet CrO_3 on alumina with microwave irradiation,¹¹³ MeReO_3 ,¹¹⁴ HNO_3 with a $\text{Yb}(\text{OTf})_3$ catalyst,¹¹⁵ $\text{FeBr}_3\text{-H}_2\text{O}_2$,¹¹⁶ a catalytic amount of AuSiO_2 ,¹¹⁷ cerium (IV) immobilized on silica with NaBrO_3 ,¹¹⁸ a bismuth catalyst,¹¹⁹ O_2 with transition metal

¹⁰⁸Though ketones are much less susceptible to further oxidation than aldehydes, such oxidation is possible (**19-8**), and care must be taken to avoid it, usually by controlling the temperature and/or the oxidizing agent.

catalysts,¹²⁰ RuO₂ with a zeolite catalyst,¹²¹ and CuCl–phenanthroline.¹²²

Tetrapropylammonium perruthenate (Pr₄N⁺ RuO₄⁻; also called TPAP; the *Ley reagent*)¹²³ has become an important oxidizing agent. This reagent has been bound to a polymer.¹²⁴ In the presence of molecular oxygen, it is catalytic in TPAP.¹²⁵ A polymer-bound morpholine *N*-oxide has been used in conjunction with a catalytic amount of TPAP.¹²⁶ Propargylic alcohols are oxidized to propargylic aldehydes with TiCl₄/NEt₃.¹²⁷ Methods have been developed for recovery of the catalyst and reuse of TPAP.¹²⁸

Most of these reagents also oxidize secondary alcohols to ketones. Reagents that can be used specifically to oxidize a secondary OH group in the presence of a primary OH group¹²⁹ are H₂O₂–ammonium molybdate,¹³⁰ NaBrO₃–CAN,¹³¹ and NaOCl in HOAc,¹³² while RuCl₂(PPh₃)₃–benzene,¹³³

osmium tetroxide,¹³⁴ and $\text{Br}_2\text{Ni}(\text{OBz})_2$ ¹³⁵ oxidize primary OH groups in the presence of a secondary OH group.¹³⁶ Benzylic and allylic alcohols have been selectively oxidized to the aldehydes in the presence of saturated alcohols by the use of potassium manganate KMnO_4 under phase-transfer conditions.¹³⁷ On the other hand, Fremy's salt (see **19-4**) selectively oxidizes benzylic alcohols and not allylic or saturated ones.¹³⁸ Certain zirconocene complexes can selectively oxidize only one OH group of a diol, even if both are primary.¹³⁹ α -Hydroxy ketones are oxidized to 1,2-diketones with $\text{Bi}(\text{NO}_3)_3$ and a $\text{Cu}(\text{OAc})_2$ catalyst,¹⁴⁰ ferric chloride (solid state),¹⁴¹ or O_2 and a vanadium catalyst.¹⁴² Tetrabutylammonium periodate oxidizes primary alcohols to aldehydes,¹⁴³ as does benzyltriphenylphosphonium periodate.¹⁴⁴ α -Hydroxyl phosphonate esters are oxidized to the α -keto phosphonate ester with zinc dichromate, without solvent¹⁴⁵ or with CrO_3 on alumina with microwave irradiation.¹⁴⁶

O-Trimethylsilyl ethers of benzylic alcohols are oxidized to the corresponding aldehyde with CrO_3 on wet alumina.¹⁴⁷ Treatment with $\text{MnO}_2/\text{AlCl}_3$ leads to similar oxidation,¹⁴⁸ as does NaBrO_3 in aq. MeCN¹⁴⁹ or K_2FeO_4 on clay.¹⁵⁰ Oxidation of trimethylsilyl ethers with O_2 , a catalytic amount of *N*-hydroxyphthalimide and a cobalt catalyst give an aldehyde.¹⁵¹ Microwave irradiation with BiCl_3 oxidizes benzylic TMS ethers to the aldehyde.¹⁵² Microwave irradiation on zeolite supported ferric nitrate has been used.¹⁵³ *O*-Tetrahydropyranyl ethers (*O*-THP) have been oxidized to the aldehyde with ferric nitrate on zeolites.¹⁵⁴

2. *The Oppenauer Oxidation.* When a ketone in the presence of an aluminum alkoxide is used as the oxidizing agent (it is reduced to a secondary alcohol), the reaction is known as the *Oppenauer oxidation*.¹⁵⁵ This is the reverse of the Meerwein–Ponndorf–Verley reaction (19-36) and the mechanism is also the reverse. The ketones most commonly used are acetone, butanone, and cyclohexanone. The most common base is aluminum *tert*-butoxide. The chief advantage of the method is its high selectivity. Although the method is most often used for the preparation of ketones, it has also been used for aldehydes. An iridium catalyst¹⁵⁶ has been developed for the Oppenauer oxidation, and also a water-soluble iridium catalyst¹⁵⁷ An uncatalyzed reaction under supercritical conditions was reported.¹⁵⁸
3. *With DMSO-Based Reagents.* An alcohol is treated with DMSO, DCC,¹⁵⁹ and anhydrous phosphoric acid¹⁶⁰ in what is called *Moffatt oxidation*. In this way, a primary alcohol can be converted to the aldehyde with no carboxylic acid being produced. The strong acid conditions are sometimes a problem, and complete removal of the dicyclohexylurea by-product can be difficult. The use of oxalyl chloride and DMSO at low temperature, the Swern oxidation,¹⁶¹ is generally more practical and widely used. Maintaining the low reaction temperature is essential in this reaction however, since the reagent generated *in situ* decomposes at temperatures significantly below ambient.

Similar oxidation of alcohols has been carried out with DMSO and other reagents¹⁶² in place of DCC: acetic anhydride,¹⁶³ SO₃–pyridine–triethylamine,¹⁶⁴ trifluoroacetic anhydride,¹⁶⁵ tosyl chloride,¹⁶⁶ Ph₃P⁺Br⁻,¹⁶⁷

¹⁵⁵For a review, see Djerassi, C. *Org. React.* **1951**, 6, 207. For the use of new catalysts see Akamanchi, K.G.; Chaudhari, B.A. *Tetrahedron Lett.* **1997**, 38, 6925; Ooi, T.; Miura, T.; Itagaki, Y.; Ichikawa, H.; Maruoka, K. *Synthesis* **2002**, 279.

The reagent has an indefinite shelf-life in a sealed container, but hydrolysis occurs upon long-term exposure to atmospheric moisture. A note of CAUTION! The Dess–Martin reagent can be shock sensitive under some conditions and explode $>200^{\circ}\text{C}$.²⁰² Other hypervalent iodine oxidizing reagents are known,²⁰³ including $\text{PhI}(\text{OAc})_2/\text{TEMPO}$,²⁰⁴ $\text{PhI}(\text{OAc})_2$ –chromium salen,²⁰⁵ stabilized iodoxybenzoic acid,²⁰⁶ and $\text{PhI}(\text{OAc})_2$ supported on alumina with microwave irradiation.²⁰⁷ Microwave irradiation of benzylic alcohols with $\text{PhI}(\text{OH})\text{OTs}$ gave the corresponding aldehyde.²⁰⁸ Hypervalent iodine compounds have been used in ionic liquids.²⁰⁹ Heating benzylic alcohols with *o*-iodoxybenzoic acid under solvent-free conditions gave the aldehyde.²¹⁰ Cyclopropylcarbinyl alcohols are oxidized to the corresponding cyclopropyl ketone or aldehyde with PhIO and a chromium–salen catalyst.²¹¹ The Dess–Martin reagent oxidized aryl aldoximes to aryl aldehydes.²¹²

6. *By Catalytic Dehydrogenation.* For the conversion of primary alcohols to aldehydes, dehydrogenation catalysts have the advantage over strong oxidizing agents that further oxidation to the carboxylic acid is prevented. Copper chromite is the agent most often used, but other catalysts (e.g., silver and copper) have also been employed. Many ketones were prepared in this manner. Catalytic dehydrogenation is more often used industrially than as a laboratory method. However, procedures using copper oxide,²¹³ copper(II) complexes,²¹⁴ rhodium complexes,²¹⁵ ruthenium complexes,²¹⁶ Raney nickel,²¹⁷ and palladium complexes²¹⁸ (under phase-transfer conditions)²¹⁹

chiral ketone oxidizes 1,2-diols to α -hydroxy ketones enantioselectively.²³⁷ Potassium monoperoxysulfate also oxidizes secondary alcohols in the presence of O₂.²³⁸ Air in the presence of a zeolite oxidizes benzylic alcohols.²³⁹ The reagent Br⁺(collidine)₂PF₆ oxidizes benzylic alcohols to the corresponding aldehyde.²⁴⁰ Sodium hypochlorite in acetic acid is useful for oxidizing larger amounts of secondary alcohols.²⁴¹ Calcium hypochlorite on moist alumina with microwave irradiation has been used to oxidize benzylic alcohols.²⁴² Chlorosulfines, Ar(Cl)S=N-t-Bu, oxidize primary alcohols to aldehydes.²⁴³ This latter reagent is generated from ArS-NH-t-Bu and NCS.²⁴⁴ Benzylic alcohols are converted to aldehydes with DBU (p. \$\$\$) and Ar₃BCl₂.²⁴⁵ Microwave irradiation of benzylic alcohols with Co(CO₃)₂ on silica gel generates the aryl aldehyde.²⁴⁶

Primary and secondary alcohols can also be oxidized, indirectly, through their esters (see **19-21**). In some cases, isolation of the ester is not required and the alcohol can then be oxidized to the aldehyde or ketone in one step.

The mechanism of oxidation with acid dichromate has been intensely studied.²⁴⁷ The currently accepted mechanism is essentially that proposed by Westheimer.²⁴⁸ The first two steps constitute an example of category 4 (p. 1706).

The base in the second step may be water, although it is also possible²⁴⁹ that in some cases no external base is involved and that the proton is transferred directly to one of the CrO₃H oxygens in which case the Cr(IV) species

produced would be H₂CrO₃. Part of the evidence for this mechanism was the isotope effect of ~ 6 found on use of MeCDOHMe, showing that the hydrogen is removed in the rate-determining step.²⁵⁰ Note that, as in **19-23** the substrate is oxidized by three different oxidation states of chromium.²⁵¹

With other oxidizing agents, mechanisms are less clear.²⁵² It seems certain that some oxidizing agents operate by a hydride-shift mechanism,²⁵³ for example,

19-4 Oxidation of Phenols and Aromatic Amines to Quinones

1/0,6/0-Dihydro-elimination

Ortho and para diols are easily oxidized to ortho- and para-quinones, respectively.²⁵⁸ Either or both OH groups can be replaced by NH_2 groups to give the same products, although for the preparation of ortho-quinones only OH groups are normally satisfactory. The reaction has been successfully carried out with other groups para to OH or NH_2 ; halogen, OR, Me, *t*-Bu, and even H, although with the last yields are poor. Many oxidizing agents have been used: acid dichromate,²⁵⁹ silver oxide, silver carbonate, lead tetraacetate, HIO_4 , NBS— H_2O — H_2SO_4 ,²⁶⁰ MnO_2 on Bentonite with microwave irradiation,²⁶¹ dimethyl dioxirane,²⁶² and atmospheric oxygen,²⁶³ to name a few. Substituted phenols, such as 4-($CH_2CH_2CH_2COOH$) phenol, are oxidized with a polymer-bound hypervalent iodine reagent to give a quinone with a spirocyclic lactone unit at C-4.²⁶⁴ Oxidation

has been done photochemically with O_2 and tetraphenylporphine.²⁶⁵ A particularly effective reagent for rings with only one OH or NH_2 group is $(KSO_3)_2N-O\cdot$ (dipotassium nitrosodisulfonate; *Fremy's salt*), which is a stable free radical.²⁶⁶ Phenols, even some whose para positions are unoccupied, can be oxidized to ortho-quinones with diphenylseleninic anhydride.²⁶⁷ Quinoid coupling products are obtained from substituted phenol treated with O_2 , a dicopper complex, and mushroom tyrosinase.²⁶⁸

Less is known about the mechanism than is the case for **19-3**, but, as in that case, it seems to vary with the oxidizing agent. For oxidation of catechol with $NaIO_4$, it was found that the reaction conducted in $H_2^{18}O$ gave unlabeled quinone,²⁶⁹ so the following mechanism²⁷⁰ was proposed:

When catechol was oxidized with MnO_4^- under aprotic conditions, a semiquinone radical ion intermediate was involved.²⁷¹ For autoxidations²⁷² (i.e., with atmospheric oxygen) a free-radical mechanism is known to operate.²⁷³

²⁷⁵Yamazaki, S. *Synth. Commun.* **1997**, 27, 3559; Juršić, B. *J. Chem. Res. (S)* **1988**, 168.

$\text{K}_2\text{S}_2\text{O}_8/\text{NiSO}_4$,²⁷⁶ $\text{Me}_3\text{N/O/OsO}_4$,²⁷⁷ $\text{Ru/Al}_2\text{O}_3/\text{O}_2$,²⁷⁸ and $\text{CuCl/O}_2/\text{pyridine}$.²⁷⁹ Several methods have been reported for the dehydrogenation of secondary amines to imines.²⁸⁰ Among them²⁸¹ are treatment with (1) iodosylbenzene (PhIO) alone or in the presence of a ruthenium complex,²⁸² (2) DMSO and oxalyl chloride,²⁸³ and (3) *t*-BuOOH and a ruthenium catalyst.²⁸⁴ *N*-Tosyl aziridines are converted to *N*-tosyl imines when heated with a palladium catalyst.²⁸⁵ An interesting variation treats pyrrolidine with iodobenzene and a rhodium catalyst to give 2-phenylpyrroline.²⁸⁶

A reaction that involves dehydrogenation to an imine that then reacts further is the reaction of primary or secondary amines²⁸⁷ with palladium black.²⁸⁸ The imine initially formed by the dehydrogenation reacts with another molecule of the same or a different amine to give an aminal, which loses NH_3 or RNH_2 to give a secondary or tertiary amine. An example is the reaction between *N*-methylbenzylamine and butylmethylamine, which produces 95% *N*-methyl-*N*-butylbenzylamine.

19-6 Oxidation of Hydrazines, Hydrazones, and Hydroxylamines

1/*N*,2/*N*-Dihydro-elimination

N,N'-Diarylhydrazines (hydrazo compounds) are oxidized to azo compounds by several oxidizing agents, including NaOBr, HgO ,²⁸⁹ $\text{K}_3\text{Fe}(\text{CN})_6$ under phase-transfer

conditions²⁹⁰ or with galvinoxyl,²⁹¹ FeCl₃,²⁹² MnO₂ (this reagent yields cis-azo-benzenes),²⁹³ CuCl₂, and air and NaOH.²⁹⁴ The reaction is also applicable to *N,N'*-dialkyl- and *N,N'*-diacylhydrazines. Hydrazines (both alkyl and aryl) substituted on only one side also give azo compounds,²⁹⁵ but these are unstable and decompose to nitrogen and the hydrocarbon:

Aniline derivatives are converted to azo compounds by heating with cetyltrimethylammonium dichromate in chloroform.²⁹⁶ When hydrazones are oxidized with HgO, Ag₂O, MnO₂, lead tetraacetate, or certain other oxidizing agents, diazo compounds are obtained:²⁹⁷

Hydrazones of the form ArCH=NNH₂ react with HgO in solvents, such as diglyme or ethanol, to give nitriles ArCN.²⁹⁸ It is possible to oxidize dimethylhydrazones (R-C=N-NMe₂) to the corresponding nitrile (R-C≡N) with MeReO₃/H₂O₂,²⁹⁹ magnesium monoperoxyphthalate (MMPP),³⁰⁰ or with dimethyl dioxirane.³⁰¹ Oxone[®] on wet alumina also converts hydrazones to nitriles with microwave irradiation.³⁰²

In a related reaction, primary aromatic amines have been oxidized to azo compounds by a variety of oxidizing agents, among them MnO₂, lead tetraacetate, O₂ and a base, barium permanganate,³⁰³ and sodium perborate in acetic acid. *tert*-Butyl hydroperoxide has been used to oxidize certain primary amines to azoxy compounds.³⁰⁴ Aromatic hydroxylamines (Ar-NH-OH) are easily oxidized to nitroso compounds (Ar-N=O), most commonly by acid dichromate.³⁰⁵ Oximes of

B. Oxidations Involving Cleavage of Carbon–Carbon Bonds³¹⁰

19-7 Oxidative Cleavage of Glycols and Related Compounds

2/O-De-hydrogen-uncoupling

1,2-Glycols are easily cleaved under mild conditions and in good yield with periodic acid or lead tetraacetate.³¹¹ The products are 2 equivalents of aldehyde, or 2 equivalents of ketone, or 1 equivalent of each, depending on the groups attached to the two carbons. The yields are so good that alkenes are often converted to glycols (**15-48**), and then cleaved with HIO_4 or Pb(OAc)_4 rather than being cleaved directly with ozone (**19-9**) or dichromate or permanganate (**19-10**). The diol can be generated and cleaved *in situ* from an alkene to give the carbonyl compounds.³¹²

³¹²Yu, W.; Mei, Y.; Kang, Y.; Hua, Z.; Jin, Z. *Org. Lett.* **2004**, *6*, 3217.

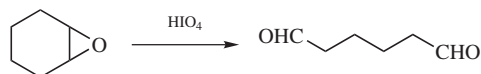

A number of other oxidizing agents also give the same products, among them³¹³ activated MnO_2 ,³¹⁴ O_2 and a ruthenium catalyst,³¹⁵ $\text{PPh}_3\text{-DEAD}$,³¹⁶ and pyridinium chlorochromate.³¹⁷ Permanganate, dichromate, and several other oxidizing agents³¹⁸ also cleave glycols, giving carboxylic acids rather than aldehydes, but these reagents are seldom used synthetically. Electrochemical oxidation is an efficient method, and is useful not only for diols, but also for their mono- and dimethoxy derivatives.³¹⁹

The two reagents (periodic acid and lead tetraacetate) are complementary, since periodic acid is best used in water and lead tetraacetate in organic solvents. Chiral lead carboxylates have been prepared for the oxidative cleavage of 1,2-diols.³²⁰ When three or more OH groups are located on adjacent carbons, the middle one (or ones) is converted to formic acid.

Other compounds that contain oxygens or nitrogens on adjacent carbons undergo similar cleavage:

Cyclic 1,2-diamines are cleaved to diketones with dimethyl dioxirane.³²¹ α-Diketones and α-hydroxy ketones are also cleaved by alkaline H_2O_2 .³²² The HIO_4 has been used to cleave epoxides to aldehydes,³²³ for example,

α-Hydroxy acids and α-keto acids are not cleaved by HIO_4 , but are cleaved by NaIO_4 in methanol in the presence of a crown ether,³²⁴ $\text{Pb}(\text{OAc})_4$, alkaline H_2O_2 ,

and other reagents. These are oxidative decarboxylations. α -Hydroxy acids give aldehydes or ketones, and α -keto acids give carboxylic acids. Also see, **19-12** and **19-13**.

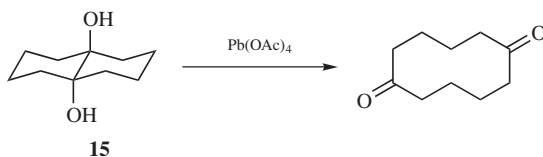

The mechanism of glycol oxidation with $\text{Pb}(\text{OAc})_4$ was proposed by Criegee.³²⁵

This mechanism is supported by these facts: (1) the kinetics are second order (first order in each reactant); (2) added acetic acid retards the reaction (drives the equilibrium to the left); and (3) *cis*-glycols react much more rapidly than *trans*-glycols.³²⁶ For periodic acid, the mechanism is similar, with the intermediate³²⁷

However, the cyclic-intermediate mechanism cannot account for all glycol oxidations, since some glycols that cannot form such an ester (e.g., **15**) are nevertheless cleaved by lead tetraacetate

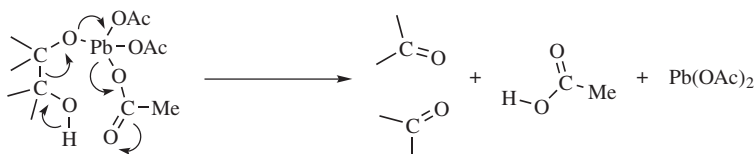

³²⁵Criegee, R.; Kraft, L.; Rank, B. *Liebigs Ann. Chem.* **1933**, 507, 159. For reviews, see Waters, W.A. *Mechanisms of Oxidation of Organic Compounds*, Wiley, NY, **1964**, pp. 72–81; Stewart, R. *Oxidation Mechanisms*, W.A. Benjamin, NY, **1964**, pp. 97–106.

(though other glycols that cannot form cyclic esters are *not* cleaved, by either reagent³²⁸). To account for cases like **15**, a cyclic transition state has been proposed:³²⁶

OS IV, 124; VII, 185; VIII, 396.

19-8 Oxidative Cleavage of Ketones, Aldehydes, and Alcohols

Cycloalkanone oxidative ring opening

Oxidative cleavage of open-chain ketones or alcohols³²⁹ is seldom a useful preparative procedure, not because these compounds do not undergo oxidation (they do, except for diaryl ketones), but because the result is generally a hopeless mixture. Aryl methyl ketones, such as acetophenone, however, are readily oxidized to aryl carboxylic acids with Re_2O_7 and 70% aqueous *tert*-butyl hydroperoxide.³³⁰ Oxygen with a mixture of manganese and cobalt catalysts give similar oxidative cleavage,³³¹ and do hypervalent iodine compounds.³³² 1,3-Diketones, such as 1,3-diphenyl-1,3-propanedione, are oxidatively cleaved with aqueous Oxone[®] to give benzoic acid.³³³ Noted that in the presence of benzaldehyde, aliphatic ketones are cleaved to give aliphatic carboxylic acids by treatment with $\text{BF}_3(\text{g})$ in refluxing hexane.³³⁴ Aldehydes, such as PhCH_2CHO , are cleaved to benzaldehyde with phosphonium dichromate in refluxing acetonitrile.³³⁵

Despite problems with acyclic ketones, the reaction is quite useful for cyclic ketones and the corresponding secondary alcohols, the dicarboxylic acid being prepared in good yield. The formation of adipic acid from cyclohexanone (shown above) is an important industrial procedure. Acid dichromate and permanganate are the most common oxidizing agents, although autoxidation (oxidation with

atmospheric oxygen) in alkaline solution³³⁶ and potassium superoxide under phase-transfer conditions³³⁷ have also been used. Other reagents include LiOCl/Chlorox³³⁸ and MeOCO₂Me at 195°C.³³⁹ Silyl-ketones have been cleaved to esters using electrolysis in alcohol solvents.³⁴⁰ Cyclic 1,3-diketones are converted to α,ω-diester with an excess of KHSO₅ in methanol.³⁴¹ Cyclic α-chloro ketones are cleaved to give an α,ω-functionalized compound (acetal-ester) when treated with cerium (IV) sulfate tetrahydrate and O₂.³⁴²

Cyclic ketones can also be cleaved by treatment with NOCl and an alcohol in liquid SO₂ to give an ω-oximinocarboxylic ester, for example,³⁴³

Cyclic 1,3-diketones, which exist mainly in the mono-enolic form, can be cleaved with sodium periodate with loss of one carbon, for example,³⁴⁴

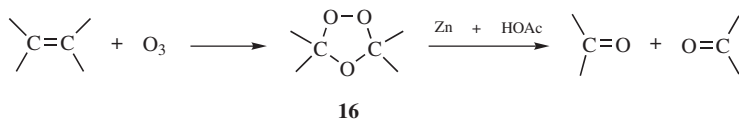

The species actually undergoing the cleavage is the triketone, so this is an example of **19-7**.

When compounds containing double bonds are treated with ozone, usually at low temperatures, they are converted to compounds called *ozonides* (**16**) that can be isolated but, because some of them are explosive, are more often decomposed with zinc and acetic acid, or catalytic hydrogenation to give 2 equivalents of aldehyde, or 2 equivalents of ketone, or 1 equivalent of each, depending on the groups attached to the alkene.³⁴⁵ The decomposition of **16** has also been carried out with triethylamine³⁴⁶ and with reducing agents, among them trimethyl phosphite,³⁴⁷ thiourea,³⁴⁸ and dimethyl sulfide.³⁴⁹ However, ozonides can also be *oxidized* with oxygen, peroxycids, or H₂O₂ to give ketones and/or carboxylic acids or *reduced* with LiAlH₄, NaBH₄, BH₃, or catalytic hydrogenation with excess H₂ to give 2 equivalents alcohol.³⁵⁰ Ozonides can also be treated with ammonia, hydrogen, and a catalyst to give the corresponding amines,³⁵¹ or with an alcohol and anhydrous HCl to give the corresponding carboxylic esters.³⁵² Ozonolysis is therefore an important synthetic reaction.

A wide variety of alkenes undergo ozonolysis, including cyclic ones, where cleavage gives rise to one bifunctional product. Alkenes in which the double bond is connected to electron-donating groups react many times faster than those in which it is connected to electron-withdrawing groups.³⁵³ The reaction has often been carried out on compounds containing more than one double bond; generally all the bonds are cleaved. In some cases, especially when bulky groups are present, conversion of the substrate to an epoxide (**15-50**) becomes an important side reaction and can be the main reaction.³⁵⁴ Rearrangement is possible in some cases.³⁵⁵ Ozonolysis of triple bonds³⁵⁶ is less common and the reaction proceeds less easily,

since ozone is an electrophilic agent³⁵⁷ and prefers double to triple bonds (p. 1017). Compounds that contain triple bonds generally give carboxylic acids, although sometimes ozone oxidizes them to α -diketones (**19-26**). Aromatic compounds are also attacked less readily than alkenes, but have often been cleaved. Aromatic compounds behave as if the double bonds in the Kekulé structures were really there. Thus benzene gives three equivalents of glyoxal (HCOCHO), and *o*-xylene gives a glyoxal/MeCOCHO/MeCOCOME ratio of 3:2:1, which shows that in this case cleavage is statistical. With polycyclic aromatic compounds the site of attack depends on the structure of the molecule and on the solvent.³⁵⁸

Although a large amount of work has been done on the mechanism of ozonization (formation of **16**), not all the details are known. The basic mechanism was formulated by Criegee.³⁵⁹ The first step of the Criegee mechanism³⁶⁰ is a 1,3-dipolar addition (**15-58**) of ozone to the substrate to give the “initial” or “primary” ozonide, the structure of which has been shown to be the 1,2,3-trioxolane, **17**, by microwave and other spectral methods.³⁶¹ A primary ozonide has been trapped.³⁶² However, **17** is highly unstable and cleaves to an aldehyde or ketone (**18**) and an intermediate,³⁶³ which Criegee showed as a zwitterion (**19**), but which may be a diradical (**20**). This compound is usually referred to as a carbonyl oxide.³⁶⁴ The carbonyl oxide (which we will represent as **19**) can then undergo various reactions, three of which lead to normal products. One is a recombination with **18**, the second

³⁶³A Criegee intermediate has been detected for the ozonolysis of 2-butene; see Fajgar, R.; Vítek, J.; Haas, Y.; Pola, J. *Tetrahedron Lett.* **1996**, *37*, 3391.

³⁶⁴For reviews of carbonyl oxides, see Sander, W. *Angew. Chem. Int. Ed.* **1990**, *29*, 344; Brunelle, W.H. *Chem. Rev.* **1991**, *91*, 335.

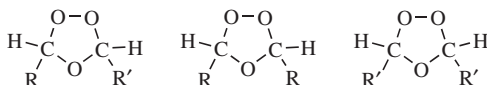

a dimerization to the bis(peroxide) **21**, and the third a kind of dimerization to **22**.³⁶⁵ If the first path is taken (this is normally

possible only if **15** is an aldehyde; most ketones do not do this³⁶⁶) the product is an ozonide (a 1,2,4-trioxolane),³⁶⁷ and hydrolysis of the ozonide gives the normal products. If **21** is formed, hydrolysis of it gives one of the products, and, of course, **18**, which then does not undergo further reaction, is the other. Intermediate **22**, if formed, can decompose directly, as shown, to give the normal products and oxygen. In protic solvents, **19** is converted to a hydroperoxide, and these have been isolated, for example,

from $\text{Me}_2\text{C}=\text{CMe}_2$ in methanol. Further evidence for the mechanism is that **21** can be isolated in some cases, for example, from $\text{Me}_2\text{C}=\text{CMe}_2$. But perhaps the most impressive evidence comes from the detection of cross-products. In the Criegee mechanism, the two parts of the original alkene break apart and then recombine to form the ozonide. In the case of an unsymmetrical alkene, $\text{RCH}=\text{CHR}'$, there should be three ozonides:

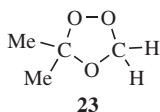

³⁶⁵Fliszár, S.; Chylińska, J.B. *Can. J. Chem.* **1967**, *45*, 29; **1968**, *46*, 783.

³⁶⁶It follows that tetrasubstituted alkenes do not normally give ozonides. However, they do give the normal cleavage products (ketones) by the other pathways. For the preparation of ozonides from tetrasubstituted alkenes by ozonolysis on polyethylene, see Griesbaum, K.; Volpp, W.; Greinert, R.; Greunig, H.; Schmid, J.; Henke, H. *J. Org. Chem.* **1989**, *54*, 383.

³⁶⁷Kamata, M.; Komatsu, K.I.; Akaba, R. *Tetrahedron Lett.* **2001**, *42*, 9203. For a report of an isolable ozonide, see dos Santos, C.; de Rosso, C.R.S.; Imamura, P.M. *Synth. Commun.* **1999**, *29*, 1903.

since there are two different aldehydes **18** and two different species **19**, and these can recombine in the three ways shown. Actually *six* ozonides, corresponding to the *cis* and *trans* forms of these three, were isolated and characterized for methyl oleate.³⁶⁸ Similar results have been reported for smaller alkenes, for example, 2-pentene, 4-nonene, and even 2-methyl-2-pentene.³⁶⁹ The last-mentioned case is especially interesting, since it is quite plausible that this compound would cleave in only one way, so that only one ozonide (in *cis* and *trans* versions) would be found; but this is not so, and three were found for this case too. However, terminal alkenes give little or no cross-ozonide formation.³⁷⁰ In general, the less alkylated end of the alkene tends to go to **18** and the other to **19**. Still other evidence³⁷¹ for the Criegee mechanism is (1) When $\text{Me}_2\text{C}=\text{CMe}_2$ was ozonized in the presence of

HCHO , the ozonide **23** could be isolated;³⁷² (2) **19** prepared in an entirely different manner (photooxidation of diazo compounds), reacted with aldehydes to give ozonides;³⁷³ and (3) *cis*- and *trans*-alkenes generally give the same ozonide, which would be expected if they cleave first.³⁷⁴ However, this was not true for $\text{Me}_3\text{CCH}=\text{CHCMe}_3$, where the *cis*-alkene gave the *cis*-ozonide (chiefly), and the *trans* gave the *trans*.³⁷⁵ The latter result is not compatible with the Criegee mechanism. Also incompatible with the Criegee mechanism was the finding that the *cis*/*trans* ratios of symmetrical (cross) ozonides obtained from *cis*- and *trans*-4-methyl-2-pentene were not the same.³⁷⁶

³⁶⁸Riezebos, G.; Grimmelikhuisen, J.C.; van Dorp, D.A. *Recl. Trav. Chim. Pays-Bas* **1963**, *82*, 1234; Privett, O.S.; Nickell, E.C. *J. Am. Oil Chem. Soc.* **1964**, *41*, 72.

³⁷²Even ketones can react with **19** to form ozonides, provided they are present in large excess: Criegee, R.; Korber, H. *Chem. Ber.* **1971**, *104*, 1812.

³⁷³Murray, R.W.; Suzui, A. *J. Am. Chem. Soc.* **1973**, *95*, 3343; Higley, D.P.; Murray, R.W. *J. Am. Chem. Soc.* **1974**, *96*, 3330.

³⁷⁴See, for example, Murray, R.W.; Williams, G.J. *J. Org. Chem.* **1969**, *34*, 1896.

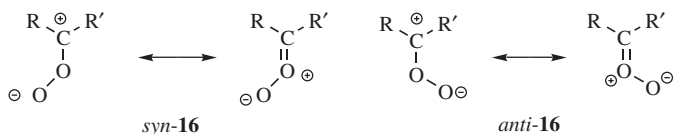

³⁷⁵Schröder, G. *Chem. Ber.* **1962**, *95*, 733; Kolsaker, P. *Acta Chem. Scand. Ser. B* **1978**, *32*, 557.

³⁷⁶Murray, R.W.; Youssefyeh, R.D.; Story, P.R. *J. Am. Chem. Soc.* **1966**, *88*, 3143, 3655; Story, P.R.; Murray, R.W.; Youssefyeh, R.D. *J. Am. Chem. Soc.* **1966**, *88*, 3144. Also see, Greenwood, F.L. *J. Am. Chem. Soc.* **1966**, *88*, 3146; Choe, J.; Srinivasan, M.; Kuczowski, R.L. *J. Am. Chem. Soc.* **1983**, *105*, 4703.

If the Criegee mechanism operated as shown above, the cis/trans ratio for each of the two cross-ozonides would have to be identical for the cis- and trans-alkenes, since in this mechanism they are completely cleaved.

The above stereochemical results have been explained³⁷⁷ on the basis of the Criegee mechanism with the following refinements: (1) The formation of **17** is stereospecific, as expected from a 1,3-dipolar cycloaddition. (2) Once they are formed, **19** and **18** remain attracted to each other, much like an ion pair. (3) Intermediate **19** exists in syn and anti forms, which are produced in different amounts and can hold their shapes, at least for a time. This is

plausible if we remember that a C=O canonical form contributes to the structure of **19**. (4) The combination of **19** and **18** is also a 1,3-dipolar cycloaddition, so configuration is retained in this step too.³⁷⁸

Evidence that the basic Criegee mechanism operates even in these cases comes from ¹⁸O labeling experiments, making use of the fact, mentioned above, that mixed ozonides (e.g., **23**) can be isolated when an external aldehyde is added. Both the normal and modified Criegee mechanisms predict that if ¹⁸O-labeled aldehyde is added to the ozonolysis mixture, the label will appear in the ether oxygen (see the reaction between **19** and **18**), and this is what is found.³⁷⁹ There is evidence that the *anti-19* couples much more readily than the *syn-19*.³⁸⁰

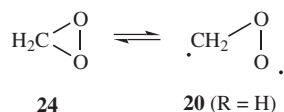

³⁷⁷Bauld, N.L.; Thompson, J.A.; Hudson, C.E.; Bailey, P.S. *J. Am. Chem. Soc.* **1968**, *90*, 1822; Bailey, P.S.; Ferrell, T.M. *J. Am. Chem. Soc.* **1978**, *100*, 899; Keul, H.; Kuczkowski, R.L. *J. Am. Chem. Soc.* **1985**, *50*, 3371.

³⁷⁸For isotope-effect evidence that this step is concerted in some cases, see Choe, J.; Painter, M.K.; Kuczkowski, R.L. *J. Am. Chem. Soc.* **1984**, *106*, 2891. However, there is evidence that it may not always be concerted: See, for example, Murray, R.W.; Su, J. *J. Org. Chem.* **1983**, *48*, 817.

Soc.* **1972**, *94*, 7609; Higley, D.P.; Murray, R.W. *J. Am. Chem. Soc.* **1976**, *98*, 4526; Mazur, U.; Kuczkowski, R.L. *J. Org. Chem.* **1979**, *44*, 3185.

³⁸⁰Mile, B.; Morris, G.M. *J. Chem. Soc. Chem. Commun.* **1978**, 263.

The ozonolysis of ethylene³⁸¹ in the liquid phase (without a solvent) was shown to take place by the Criegee mechanism.³⁸² This reaction has been used to study the structure of the intermediate **19** or **20**. The compound dioxirane (**24**) was identified in the reaction mixture³⁸³ at low temperatures and is probably in equilibrium with the biradical **20** (R = H). Dioxirane has been produced in solution, but it oxidatively cleaves dialkyl ethers (e.g., Et—O—Et) via a chain radical process,³⁸⁴ so the choice of solvent is important.

Ozonolysis in the gas phase is not generally carried out in the laboratory. However, the reaction is important because it takes place in the atmosphere and contributes to air pollution.³⁸⁵ There is much evidence that the Criegee mechanism operates in the gas phase too, although the products are more complex because of other reactions that also take place.³⁸⁶

products are generally 2 equivalents of ketone, 2 equivalents of carboxylic acid, or 1 equivalent of each, depending on what groups are attached to the alkene. With ordinary solutions of permanganate or dichromate yields are generally low, and the reaction is seldom a useful synthetic method; but high yields can be obtained by oxidizing with KMnO_4 dissolved in benzene containing the crown ether dicyclohexano-18-crown-6 (see p. 120).³⁸⁸ The crown ether coordinates with K^+ , permitting the KMnO_4 to dissolve in benzene. A mixture of aq. KMnO_4 and NaIO_4 on sand is also effective.³⁸⁹ Another reagent frequently used for synthetic purposes is the *Lemieux-von Rudloff reagent*: HIO_4 containing a trace of MnO_4^- .³⁹⁰ The MnO_4^- is the actual oxidizing agent, being reduced to the manganate stage, and the purpose of the HIO_4 is to reoxidize the manganate back to MnO_4^- . Another reagent that behaves similarly is NaIO_4 -ruthenium tetroxide.³⁹¹ Cyclic alkenes are cleaved to α,ω -diketones, keto-acids or dicarboxylic acids. Cyclic alkenes are cleaved to dialdehydes with $\text{KMnO}_4 \cdot \text{CuSO}_4$ in dichloromethane.³⁹² Hydrogen peroxide on supported heteropolyacid cleaves cyclic alkenes.³⁹³ A combination of $\text{RuCl}_3/\text{HIO}_5$ oxidatively cleaves cyclic alkenes to dicarboxylic acids.³⁹⁴

The *Barbier-Wieland procedure* for decreasing the length of a chain by one carbon involves oxidative cleavage by acid dichromate (NaIO_4 -ruthenium tetroxide has also been used), but this is cleavage of a 1,1-diphenyl alkene, which generally gives good yields:

Addition of a catalytic amount of OsO_4 to Jones reagent (**19-3**) leads to good yields of the carboxylic acid from simple alkenes.³⁹⁵ A combination of Oxone[®] and OsO_4 in DMF cleaves alkenes to carboxylic acids.³⁹⁶ With certain reagents, the oxidation of double bonds can be stopped at the aldehyde stage, and in these cases the products are the same as in the ozonolysis procedure. Among these reagents are

³⁸⁸Sam, D.J.; Simmons, H.E. *J. Am. Chem. Soc.* **1972**, *94*, 4024. See also, Lee, D.G.; Chang, V.S. *J. Org. Chem.* **1978**, *43*, 1532.

tert-butyl iodoxybenzene,³⁹⁷ KMnO_4 in $\text{THF-H}_2\text{O}$,³⁹⁸ and $\text{NaIO}_4\text{-OsO}_4$.³⁹⁹ Electrolysis with LiClO_4 in aqueous acetonitrile also cleaves alkenes to give the aldehyde.⁴⁰⁰ Enol ethers, RC(OR')=CH_2 , have been cleaved to carboxylic esters, RC(OR')=O , by atmospheric oxygen.⁴⁰¹

Cleavage of alkynes is generally rather difficult, but treatment of internal alkynes with an excess of Oxone[®] with a ruthenium catalyst leads to aliphatic carboxylic acids.⁴⁰²

The mechanism of oxidation probably involves in most cases the initial formation of a glycol (**15-29**) or cyclic ester,⁴⁰³ and then further oxidation as in **19-7**.⁴⁰⁴ In line with the electrophilic attack on the alkene, triple bonds are more resistant to oxidation than double bonds. Terminal triple-bond compounds can be cleaved to carboxylic acids ($\text{RC}\equiv\text{CH} \rightarrow \text{RCOOH}$) with thallium(III) nitrate⁴⁰⁵ or with [bis-(trifluoroacetoxy)iodo]pentafluorobenzene [i.e., $\text{C}_6\text{F}_5\text{I(OCOCF}_3)_2$],⁴⁰⁶ among other reagents.

Aromatic rings can be cleaved with strong enough oxidizing agents. An important laboratory reagent for this purpose is ruthenium tetroxide along with a co-oxidant, such as NaIO_4 or NaOCl (household bleach can be used).⁴⁰⁷ Examples⁴⁰⁸ are the oxidation of naphthalene to phthalic acid⁴⁰⁹ and, even more remarkably, of cyclohexylbenzene to cyclohexanecarboxylic acid⁴¹⁰ (note the contrast with **19-11**). The latter conversion was also accomplished with ozone.⁴¹¹ Another reagent that oxidizes aromatic rings is air catalyzed by V_2O_5 . The oxidations of naphthalene to phthalic anhydride and of benzene to maleic anhydride by this reagent are

19-11 Oxidation of Aromatic Side Chains

Oxo,hydroxy-de-dihydro,methyl-tersubstitution

Alkyl chains on aromatic rings can be oxidized to COOH groups by many oxidizing agents, including permanganate, nitric acid, and acid dichromate.⁴¹⁷ The method is most often applied to the methyl group, although longer side chains can also be cleaved. However, tertiary alkyl groups are resistant to oxidation, and when they *are* oxidized, ring cleavage usually occurs too.⁴¹⁸ It is usually difficult to oxidize an R group on a fused aromatic system without cleaving the ring or oxidizing it to a quinone (**19-19**). However, this has been done (e.g., 2-methylnaphthalene was converted to 2-naphthoic acid) with aqueous Na₂Cr₂O₇.⁴¹⁹ Aryl methyl groups are oxidized to aryl COOH with NaOCl in acetonitrile,⁴²⁰ or with NBS in aq. NaOH under photochemical conditions.⁴²¹ Functional groups can be present anywhere on the side chain and, if in the α position, greatly increase the ease of oxidation. An exception is an phenyl group. In such cases, the reaction stops at the diaryl ketone stage. Molecules containing aryl groups on different carbons cleave so that each

ring gets one carbon atom, as in the cleavage of the 9,10-bond of dihydrophenanthrenes **25** to **26**.

It is possible to oxidize only one alkyl group of a ring that contains more than one. The order of reactivity⁴²² toward most reagents is $\text{CH}_2\text{Ar} > \text{CHR}_2 > \text{CH}_2\text{R} > \text{CH}_3$.⁴²³ Groups on the ring susceptible to oxidation (OH, NHR, NH_2 , etc.) must be protected. The oxidation can be performed with oxygen, in which case it is auto-oxidation, and the mechanism is like that in **14-7**, with a hydroperoxide intermediate. With this procedure it is possible to isolate ketones from ArCH_2R , and this is often done.⁴²⁴

The mechanism has been studied for the closely related reaction: $\text{Ar}_2\text{CH}_2 + \text{CrO}_3 \rightarrow \text{Ar}_2\text{C=O}$.⁴²⁵ A deuterium isotope effect of 6.4 was found, indicating that the rate-determining step is either $\text{Ar}_2\text{CH}_2 \rightarrow \text{Ar}_2\text{CH}\cdot$ or $\text{Ar}_2\text{CH}_2 \rightarrow \text{Ar}_2\text{CH}^+$. Either way this explains why tertiary groups are not converted to COOH and why the reactivity order is $\text{CHR}_2 > \text{CH}_2\text{R} > \text{CH}_3$, as mentioned above. Both free radicals and carbocations exhibit this order of stability (Chapter 5). The two possibilities are examples of categories 2 and 3 (p. 1706). Just how the radical or the cation goes on to the product is not known.

When the alkyl group is one oxidizable to COOH (**19-11**), cupric salts are oxidizing agents, and the OH group is found in a position ortho to that occupied by the alkyl group.⁴²⁶ This reaction is used industrially to convert toluene to phenol.

In another kind of reaction, an aromatic aldehyde ArCHO or ketone ArCOR' is converted to a phenol ArOH on treatment with alkaline H_2O_2 ,⁴²⁷ but there must be an OH or NH_2 group in the ortho or para position. This is called the *Dakin reaction*.⁴²⁸ The mechanism may be similar to that of the Baeyer–Villiger reaction (**18-19**).⁴²⁹

⁴²²Oxidation with Co(III) is an exception. The methyl group is oxidized in preference to the other alkyl groups: Onopchenko, A.; Schulz, J.G.D.; Seekircher, R. *J. Org. Chem.* **1972**, *37*, 1414.

⁴²³For example, see Foster, G.; Hickinbottom, W.J. *J. Chem. Soc.* **1960**, 680; Ferguson, L.N.; Wims, A.I. *J. Org. Chem.* **1960**, *25*, 668.

⁴²⁸See Schubert, W.M.; Kintner, R.R., in Patai, S. *The Chemistry of the Carbonyl Group*, Vol. 1, Wiley, NY, **1966**, pp. 749–752.

⁴²⁹For a discussion, see Hocking, M.B.; Bhandari, K.; Shell, B.; Smyth, T.A. *J. Org. Chem.* **1982**, *47*, 4208.

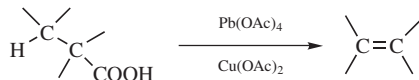

The intermediate **27** has been isolated.⁴³⁰ The reaction has been performed on aromatic aldehydes with an alkoxy group in the ring, and no OH or NH₂. In this case, acidic H₂O₂ was used.⁴³¹ The Dakin reaction has been done in ionic liquids.⁴³²

19-12 Oxidative Decarboxylation Acetoxy-de-carboxy-substitution

Hydro-carboxyl-elimination

Carboxylic acids can be decarboxylated⁴³³ with lead tetraacetate to give a variety of products, among them the ester ROAc (formed by replacement of COOH by an acetoxy group), the alkane RH (see **12-40**), and, if α, β hydrogen is present, the alkene formed by elimination of H and COOH, as well as numerous other products arising from rearrangements, internal cyclizations,⁴³⁴ and reactions with solvent molecules. When R is tertiary, the chief product is usually the alkene, which is often obtained in good yield. High yields of alkenes can also be obtained when R is primary or secondary, in this case by the use of Cu(OAc)₂ along with the Pb(OAc)₄.⁴³⁵ In the absence of Cu(OAc)₂, primary acids give mostly alkanes (though yields are

generally low) and secondary acids may give carboxylic esters or alkenes. Carboxylic esters have been obtained in good yields from some secondary acids, from β,γ -unsaturated acids, and from acids in which R is a benzylic group. Other oxidizing agents,⁴³⁶ including Co(III), Ag(II), Mn(III), and Ce(IV), have also been used to effect oxidative decarboxylation.⁴³⁷

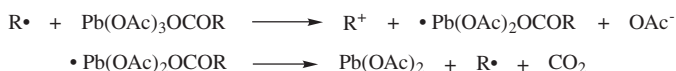

The mechanism with lead tetraacetate is generally accepted to be of the free-radical type.⁴³⁸ First, there is an interchange of ester groups:

There follows a free-radical chain mechanism (shown for **28** although **29** and other lead esters can behave similarly)

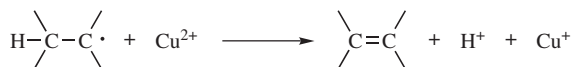

Initiation

Propagation

Products can then be formed either from $\text{R}\bullet$ or R^+ . Primary $\text{R}\bullet$ abstract H from solvent molecules to give RH. R^+ can lose H^+ to give an alkene, react with HOAc to give the carboxylic ester, react with solvent molecules or with another functional group in the same molecule, or rearrange, thus accounting for the large number of possible products. The $\text{R}\bullet$ group can also dimerize to give RR. The effect of Cu^{2+} ions⁴³⁹ is to oxidize the radicals to alkenes, thus producing good yields of alkenes from primary and secondary substrates. The Cu^{2+} ion has no effect on tertiary radicals, because these are efficiently oxidized to alkenes by lead tetraacetate.

In another type of oxidative decarboxylation, arylacetic acids can be oxidized to aldehydes with one less carbon ($\text{ArCH}_2\text{COOH} \rightarrow \text{ArCHO}$) by tetrabutylammonium periodate.⁴⁴⁰ Simple aliphatic carboxylic acids were converted to nitriles with one less carbon ($\text{RCH}_2\text{COOH} \rightarrow \text{RC}\equiv\text{N}$) by treatment with trifluoroacetic anhydride and NaNO_2 in F_3CCOOH .⁴⁴¹

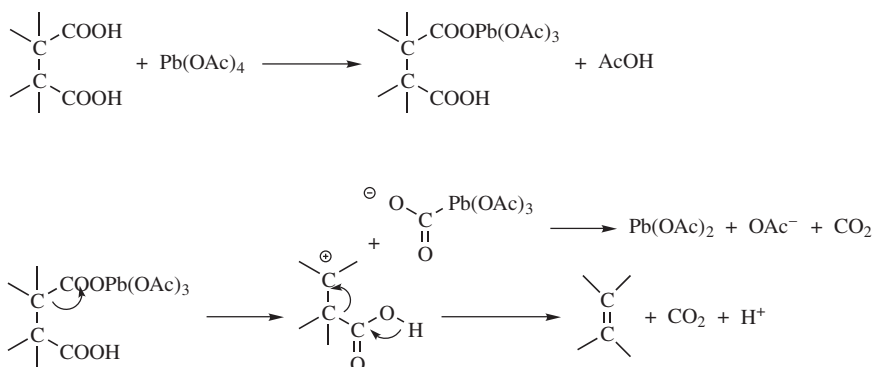

See also, 14-37.

19-13 Bisdecarboxylation

Dicarboxy-elimination

Compounds containing carboxyl groups on adjacent carbons (succinic acid derivatives) can be bisdecarboxylated with lead tetraacetate in the presence of O_2 .⁴³³ The reaction is of wide scope. The elimination is stereoselective, but not stereospecific (both *meso*- and *dl*-2,3-diphenylsuccinic acid gave *trans*-stilbene);⁴⁴² a concerted mechanism is thus unlikely. The following mechanism is not inconsistent with the data:

though a free-radical mechanism seems to hold in some cases. Bis(decarboxylation) of succinic acid derivatives to give alkenes⁴⁴³ has also been carried out by other methods, including treatment of the corresponding anhydrides with nickel, iron,

or rhodium complexes,⁴⁴⁴ by decomposition of the corresponding bis(peroxyesters),⁴⁴⁵ and electrolytically.⁴⁴⁶

Compounds containing geminal carboxyl groups (disubstituted malonic acid derivatives) can also be bisdecarboxylated with lead tetraacetate,⁴⁴⁷ *gem*-diacetates (acylals) being produced, which are easily hydrolyzable to ketones:⁴⁴⁸

A related reaction involves α -substituted aryl nitriles having a sufficiently acidic α hydrogen, which can be converted to ketones by oxidation with air under phase transfer conditions.⁴⁴⁹ The nitrile is added to NaOH in benzene or DMSO containing a catalytic amount of triethylbenzylammonium chloride (TEBA).⁴⁵⁰ This reaction could not be applied to aliphatic nitriles, but an indirect method for achieving this conversion is given in **19-60**. α -Dialkylamino nitriles can be converted to ketones, $\text{R}_2\text{C}(\text{NMe}_2)\text{CN} \rightarrow \text{R}_2\text{C}=\text{O}$, by hydrolysis with CuSO_4 in aqueous methanol⁴⁵¹ or by autoxidation in the presence of *t*-BuOK.⁴⁵²

C. Reactions Involving Replacement of Hydrogen by Heteroatoms

19-14 Hydroxylation at an Aliphatic Carbon

Hydroxylation or Hydroxy-de-hydrogenation

Compounds containing susceptible C—H bonds can be oxidized to alcohols.⁴⁵³ Nearly always, the C—H bond involved is tertiary, so the product is a tertiary alcohol. This is partly because tertiary C—H bonds are more susceptible to free-radical attack than primary and secondary bonds and partly because the reagents involved

would oxidize primary and secondary alcohols further. In the best method, the reagent is ozone and the substrate is absorbed on silica gel.⁴⁵⁴ Yields as high as 99% have been obtained by this method. Other reagents are chromic acid,⁴⁵⁵ potassium hydrogen persulfate (KHSO₅),⁴⁵⁶ ruthenium tetroxide (RuO₄),⁴⁵⁷ 2,6-dichloropyridine *N*-oxide with a ruthenium catalyst,⁴⁵⁸ thallium acetate,⁴⁵⁹ sodium chlorite (NaClO₂) with a metalloporphyrin catalyst,⁴⁶⁰ and certain peroxybenzoic acids.⁴⁶¹ Alkanes and cycloalkanes have been oxidized at secondary positions, to a mixture of alcohols and trifluoroacetates, by 30% aq. H₂O₂ in trifluoroacetic acid.⁴⁶² This reagent does not oxidize the alcohols further and ketones are not found. As in the case of chlorination with *N*-haloamines and sulfuric acid (see **14-1**), the ω - 1 position is the most favored. Another reagent⁴⁶³ that oxidizes secondary positions is iodosylbenzene, catalyzed by Fe^{III}-porphyrin catalysts.⁴⁶⁴ Use of an optically active Fe^{III}-porphyrin gave enantioselective hydroxylation, with moderate ee.⁴⁶⁵

When chromic acid is the reagent, the mechanism is probably as follows: a Cr⁶⁺ species abstracts a hydrogen to give R₃C•, which is held in a solvent cage near the resulting Cr⁵⁺ species. The two species then combine to give R₃COCr⁴⁺, which is hydrolyzed to the alcohol. This mechanism predicts retention of configuration; this is largely observed.⁴⁶⁶ The oxidation by permanganate also involves predominant retention of configuration, and a similar mechanism has been proposed.⁴⁶⁷

Treatment of double-bond compounds with selenium dioxide introduces an OH group into the allylic position (see also, **19-17**).⁴⁶⁸ This reaction also produces conjugated aldehydes in some cases.⁴⁶⁹ Allylic rearrangements are common. There is

evidence that the mechanism does not involve free radicals, but includes two pericyclic steps (A and B):⁴⁷⁰

The step marked A is similar to the ene synthesis (**15-23**). The step marked B is a [2,3]-sigmatropic rearrangement (see **18-35**). The reaction can also be accomplished with *tert*-butyl hydroperoxide, if SeO₂ is present in catalytic amounts (the *Sharpless method*).⁴⁷¹ The SeO₂ is the actual reagent; the peroxide reoxidizes the Se(OH)₂.⁴⁷² This method makes work-up easier, but gives significant amounts of side products when the double bond is in a ring.⁴⁷³ Alkynes generally give α,α' -dihydroxylation.⁴⁷⁴

Ketones and carboxylic esters can be α hydroxylated by treatment of their enolate forms (prepared by adding the ketone or ester to LDA) with a molybdenum peroxide reagent (MoO₅-pyridine-HMPA) in THF-hexane at -70°C.⁴⁷⁵ The reaction of ketones with Ti(O*i*Pr)₄, diethyl tartrate and *tert*-butylhydroperoxide gave the α -hydroxy ketone with good enantioselectivity, albeit in low yield.⁴⁷⁶ The enolate forms of amides and esters⁴⁷⁷ and the enamine derivatives of ketones⁴⁷⁸ can similarly be converted to their α hydroxy derivatives by reaction with molecular oxygen. The MoO₅ method can also be applied to certain nitriles.⁴⁷⁹ Ketones have also been α hydroxylated by treating the corresponding silyl enol ethers

19-15 Oxidation of Methylene to OH, O₂CR, or OR

Hydroxy (or alkoxy) -de-dihydro-bisubstitution

Methyl or methylene groups α to a carbonyl can be oxidized to give α -hydroxy ketones, aldehydes, or carboxylic acid derivatives. Ketones can be α hydroxylated in good yields, without conversion to the enolates, by treatment with the hypervalent iodine reagents⁴⁸³ *o*-iodosobenzoic acid⁴⁸⁴ or phenyliodoso acetate, $\text{PhI}(\text{OAc})_2$, in methanolic NaOH.⁴⁸⁵ The latter reagent has also been used on carboxylic esters.⁴⁸⁶ Dioxxygen (O₂) and a chiral phase-transfer catalyst gave enantioselective α -hydroxylation of ketones, if the α position was tertiary.⁴⁸⁷ Dimethyl dioxirane is quite effective for hydroxylation of 1,3-dicarbonyl compounds,⁴⁸⁸ and O₂ with a manganese catalyst also gives hydroxylation of such compounds.⁴⁸⁹ Oxygen with a cerium catalyst α -hydroxylates β -keto esters.⁴⁹⁰ Ceric ammonium nitrate has been used to hydroxylate C-2 of dibenzyl malonate.⁴⁹¹ Methyl ketones (RCOME) react with ammonium peroxydisulfate, $(\text{NH}_4)_2\text{S}_2\text{O}_8$, and a catalytic amount of diphenyl diselenide in MeOH to give α -keto acetals, $\text{RCOCH}(\text{OMe})_2$.⁴⁹²

α -Acetoxylation of ketones with concurrent α -arylation occurs when ketones react with $\text{Mn}(\text{OAc})_3$ in benzene.⁴⁹³ α -Acetoxylation of ketones can occur under similar conditions without arylation.⁴⁹⁴ α -Methyl ketones are converted to the α -acetoxy derivative under the same conditions.⁴⁹⁵ Thallium (III) triflate converts acetophenone to α -formyloxy acetophenone.⁴⁹⁶ α -Tosyloxy ketones are generated from acetophenone derivatives using $\text{PhI}(\text{OH})\text{OTs}$.⁴⁹⁷

A different method for the conversion of ketones to α -hydroxy ketones consists of treating the enolate anion with a 2-sulfonyloxaziridine (e.g., **30**).⁴⁹⁸ This is not a free-radical process; the following mechanism is likely:

The method is also successful for carboxylic esters^{351, 499} and N,N -disubstituted amides,⁵⁰⁰ and can be made enantioselective by the use of a chiral oxaziridine.⁵⁰¹ Dimethyldioxirane also oxidizes ketones (through their enolate forms) to α -hydroxy ketones.⁵⁰² Titanium enolates can be oxidized with *tert*-butyl hydroperoxide⁵⁰³ or with dimethyl dioxirane⁵⁰⁴ and hydrolyzed with aqueous ammonium fluoride to give the α -hydroxy ketone. Ketones are converted to the α -oxamino derivative ($\text{O}=\text{C}-\text{CH}_2-$ \rightarrow $\text{O}=\text{C}-\text{CHONHPh}$) with excellent enantioselectivity using

PhN=O and *L*-proline⁵⁰⁵ or (S)-proline.⁵⁰⁶ Aldehydes undergo a similar oxidation.⁵⁰⁷ α -Lithio sulfones have been hydroxylated with Me₃SiOO*t*-Bu.⁵⁰⁸

α -Hydroxyketones can be generated from silyl enol ethers with a catalytic amount of MeReO₃ and H₂O₂.⁵⁰⁹ Silyl ketene ethers are converted to α -hydroxy esters with H₂O₂ and methyl trioxorhenium.⁵¹⁰ The α' -position of α,β -unsaturated ketones can be selectively oxidized.⁵¹¹ *N*-Acyl amines are converted to the α -hydroxy derivative with PhIO and a manganese–salen catalyst.⁵¹² Note that homoallylic-type oxidation occurs when an α,α -dimethyl oxime ether is treated with PhI(OAc)₂ and a palladium catalyst in acetic acid–acetic anhydride, converting one of the methyl groups to an acetoxymethyl.⁵¹³

Simple alkanes can be converted to esters with dialkyloxiranes. Cyclic alkanes are oxidized to alcohols with dimethyl dioxirane.⁵¹⁴ Cyclohexane was converted to cyclohexyl trifluoroacetate with di(trifluoromethyl) dioxirane and trifluoroacetic anhydride⁵¹⁵ and also with RuCl₃/MeCO₃H/CF₃CO₂H.⁵¹⁶ Dimethyl dioxirane converts alkanes to alcohols in some cases.⁵¹⁷ Adamantane is converted to adamantyl alcohol with DDQ (p. 1710) and triflic acid.⁵¹⁸ The mechanism of oxygen insertion into alkanes has been examined.⁵¹⁹

Benzylic methylene groups are more readily oxidized to benzylic alcohols when compared to simple alkanes. Typical reagents include manganese–salen and PhIO⁵²⁰ or peroxides.⁵²¹ α -Hydroxy ethers are also generated by reaction of this reagents with ethers.⁵²² *N*-Benzyl phthalimide reacts with NBS, NaOAc, and acetic

modest enantioselectivity.⁵⁴² Cyclic amines react with *Pseudomonas oleovorans* GPoI to give hydroxy amines; *N*-benzylpyrrolidine is converted to 3-hydroxy *N*-benzylpyrrolidine.⁵⁴³ *Sphingomonas* sp. HXN-200 gives similar results.⁵⁴⁴ In a similar manner, lactams are converted to the corresponding 3-hydroxy lactam with *sphingomonas* sp. HXN-200.⁵⁴⁵ *N*-Benzyl piperidine is converted to the 4-hydroxy derivative under the same conditions.⁵⁴⁶ The reaction of tetradecanoic acid with the α -oxidase from *Pisum sativum*, in the presence of molecular oxygen, gives 2(*R*)-hydroxytetradecanoic acid with high asymmetric induction.⁵⁴⁷

19-16 Oxidation of Methylene to Heteroatom Functional Groups Other Than Oxygen or Carbonyl

Amino (or amido) -de-dihydro-bisubstitution

α -Amination or amidation of a CH unit is possible in some cases. Cyclic alkanes are converted to the *N*-alkyl *N*-tosylamine with $\text{PhI}=\text{NTs}$ and a copper complex.⁵⁴⁸ Benzylic CH, such as in ethylbenzene, is oxidized with $\text{PhI}(\text{OAc})_2$ in the presence of TsNH_2 and a fluorinated manganese porphyrin to give the corresponding *N*-tosylamine, $\text{PhCHMe}(\text{NHTs})$.⁵⁴⁹ Alkenes with an allylic CH react with $\text{PhI}=\text{NTs}$ and a ruthenium catalysts to give an allylic *N*-tosylamine.⁵⁵⁰ When an α -keto ester reacts with DEAD (diethyl azodicarboxylate) and a chiral copper complex, an α -carbamate is formed, $\text{RCH}(\text{NHCO}_2\text{Et})\text{C}(=\text{O})\text{CO}_2\text{Et}$, with modest enantioselectivity.⁵⁵¹

Similar reactions are possible, in some cases, to produce sulfur containing compounds.

Sulfo-de-dihydro-bisubstitution

Cyclic alkanes are converted to the corresponding alkylsulfonic acid with SO_2/O_2 and a vanadium catalyst.⁵⁵²

19-17 Oxidation of Methylene to Carbonyl

Oxo-de-dihydro-bisubstitution

Methyl or methylene groups α to a carbonyl can be oxidized with selenium dioxide to give, respectively, α -keto aldehydes (see **19-18**) and α -diketones.⁵⁵³ The reaction can also be carried out to an aromatic ring or to a double bond, although in the latter case, hydroxylation (see **19-14**) is the more common result. Selenium dioxide, SeO_2 , is the reagent most often used, but the reaction has also been carried out with N_2O_3 and other oxidizing agents,⁵⁵⁴ including hypervalent iodine compounds.⁵⁵⁵ Sodium nitrite/HCl oxidizes cyclic ketones to the diketone.⁵⁵⁶ Substrates most easily oxidized contain two aryl groups on CH_2 , and these substrates can be oxidized with many oxidizing agents (see **19-11**). The benzylic position of arenes have been oxidized to alkyl aryl ketones with several oxidizing agents, including CrO_3 -acetic acid,⁵⁵⁷ the Jones reagent,⁵⁵⁸ CrO_3 on silica,⁵⁵⁹ pyridinium chlorochromate,⁵⁶⁰ DDQ,⁵⁶¹ CrO_2Cl_2 with ultrasound,⁵⁶² KMnO_4 supported on MnO_2 ,⁵⁶³ KMnO_4 on alumina with microwave irradiation⁵⁶⁴ or on Montmorillonite K10 with either ultrasound or microwave irradiation,⁵⁶⁵ $\text{KMnO}_4/\text{CuSO}_4$ neat⁵⁶⁶ or with ultrasound,⁵⁶⁷ $\text{NaBrO}_3/\text{CeO}_2$,⁵⁶⁸ manganese-salen/PhIO,⁵⁶⁹ *tert*-butylhydroperoxide and a ruthenium catalyst,⁵⁷⁰ $\text{Ru}(\text{OH})_x\text{-Al}_2\text{O}_3$ and O_2 ,⁵⁷¹ hydrogen peroxide with a copper catalyst,⁵⁷² as well as with SeO_2 . The combination of O_2 and

mcpha oxidizes benzylic arenes to aryl ketones.⁵⁷³ Note that benzyl methyl ether is oxidized to methyl benzoate with KMnO_4 in the presence of benzyltriethylammonium chloride.⁵⁷⁴

Alkenes of the form $\text{C}=\text{C}-\text{CH}_2$ (an allylic position) have been oxidized to α,β -unsaturated ketones⁵⁷⁵ by sodium dichromate in $\text{HOAc}-\text{Ac}_2\text{O}$, by $t\text{-BuOOH}$ and chromium compounds,⁵⁷⁶ $t\text{-BuOOH}$ and a palladium catalyst,⁵⁷⁷ or a rhodium catalyst,⁵⁷⁸ as well as electrolytically.⁵⁷⁹ Oxygen, MeSO_3H a palladium catalysts and a molybdoanadophosphate catalyst convert cyclic alkenes to saturated cyclic ketones.⁵⁸⁰ Thallium(III) nitrate in aqueous acetic acid converts allylic alkenes to the corresponding saturated ketone, even in the presence of a primary alcohol elsewhere in the molecule.⁵⁸¹ The propargylic position of internal alkynes are oxidized to give propargylic ketones with an iron catalyst,⁵⁸² or with $\text{O}_2/t\text{-BuOOH}$ in the presence of $\text{CuCl}_2\cdot\text{H}_2\text{O}$.⁵⁸³

Cyclic amines are oxidized to lactams using a mixture of RuCl_3 and NaIO_4 .⁵⁸⁴ Lactams are also formed using KMnO_4 with benzyltriethylammonium chloride.⁵⁸⁵ Tertiary amines are converted to amides⁵⁸⁶ and cyclic tertiary amines can be converted to lactams by oxidation with $\text{Hg}^{\text{II}}\text{-EDTA}$ complex in basic solution.⁵⁸⁷ Lactams, which need not be *N*-substituted, can be converted to cyclic imides by oxidation with a hydroperoxide or peroxyacid and an Mn(II) or Mn(III) salt.⁵⁸⁸ Lactams are oxidized to cyclic imides with oxygen and $\text{Co}(\text{OAc})_2$ in the presence *N*-hydroxysuccinimide.⁵⁸⁹

Ethers in which at least one group is primary alkyl can be oxidized to the corresponding carboxylic esters in high yields with ruthenium tetroxide.⁵⁹⁰ Molecular

oxygen with a binuclear copperII complex⁵⁹¹ or PdCl₂/CuCl₂/CO⁵⁹² also converts ethers to esters. In a variation, benzyl *tert*-butyl ethers are oxidized to benzaldehyde derivatives with NO and *N*-hydroxysuccinimide.⁵⁹³ Cyclic ethers are oxidized to lactones.⁵⁹⁴ Cyclic ethers are oxidized to lactones with CrO₃/Me₃SiONO₂.⁵⁹⁵ Lactones are also formed from cyclic ethers with NaBrO₃-KHSO₄ in water.⁵⁹⁶ The reaction has also been accomplished with CrO₃ in sulfuric acid,⁵⁹⁷ and with benzyl-triethylammonium permanganate.⁵⁹⁸

Two mechanisms have been suggested for the reaction with SeO₂. One of these involves a selenate ester of the enol:⁵⁹⁹

In the other proposed mechanism,⁶⁰⁰ the principal intermediate is α β -ketoseleninic acid

and a selenate ester is not involved.

It has proved possible to convert CH₂ to C=O groups, even if they are not near any functional groups, indirectly, by the remote oxidation method of Breslow⁶² (see 19-2). In a typical example, the keto ester **31** was irradiated to give the hydroxy lactone **32**, which was dehydrated to **33**. Ozonolysis of **33** gave the diketone ester

34, in which the C-14 CH_2 group of **31** has been oxidized to a $\text{C}=\text{O}$ group.⁶⁰¹ The reaction was not completely regioselective: **34** comprised $\sim 60\%$ of the product, with the remainder consisting of other compounds in which the keto group was located at C-12, C-15, and other positions along the carbon chain. Greater regioselectivity was achieved when the aromatic portion was connected to the chain at two positions.⁶⁰² In the method so far described, the reaction takes place because one portion of a molecule (the benzophenone moiety) abstracts hydrogen from another portion of the same molecule, that is, the two portions are connected by a series of covalent bonds. However, the reaction can also be carried out where the two reacting centers are actually in different molecules, providing the two molecules are held together by hydrogen bonding. For example, one of the CH_2 groups of *n*-hexadecanol monosuccinate, $\text{CH}_3(\text{CH}_2)_{14}\text{CH}_2\text{OCOCH}_2\text{CH}_2\text{COOH}$, was oxidized to a $\text{C}=\text{O}$ group by applying the above procedure to a mixture of it and benzophenone-4-carboxylic acid *p*- $\text{PhCOC}_6\text{H}_4\text{COOH}$ in CCl_4 .⁶⁰³

Other remote oxidations⁶⁰⁴ have also been reported. Among these are conversion of aryl ketones $\text{ArCO}(\text{CH}_2)_3\text{R}$ to 1,4-diketones $\text{ArCO}(\text{CH}_2)_2\text{COR}$ by photoirradiation in the presence of such oxidizing agents as $\text{K}_2\text{Cr}_2\text{O}_7$ or KMnO_4 ,⁶⁰⁵ and conversion of alkyl ketones, $\text{RCO}(\text{CH}_2)_3\text{R}'$, to 1,3- and 1,4-diketones with $\text{Na}_2\text{S}_2\text{O}_8$ and FeSO_4 .⁶⁰⁶ 2-Octanol was oxidized to give 2-propyl-5-methyl γ -butyrolactone with lead tetraacetate in a CO atmosphere.⁶⁰⁷

It is possible to perform the conversion $\text{CH}_2 \rightarrow \text{C}=\text{O}$ on an alkane, with no functional groups at all, although the most success has been achieved with substrates in which all CH_2 groups are equivalent, such as unsubstituted cycloalkanes. One method uses H_2O_2 and bis(picolinato)iron(II). Hydrogen peroxide and trifluoroacetic acid has also been used for oxidation of alkanes.⁶⁰⁸ With this method, cyclohexane was converted with 72% efficiency to give 95% cyclohexanone and 5% cyclohexanol.⁶⁰⁹ This was also accomplished with $\text{BaRu}(\text{O})_2(\text{OH})_3$.⁶¹⁰ The same type of conversion, with lower yields (20–30%), has been achieved with the *Gif system*.⁶¹¹ There are several variations. One consists of pyridine–acetic acid, with H_2O_2 as oxidizing agent and tris(picolinato)iron(III) as catalyst.⁶¹² Other *Gif* systems use O_2 as oxidizing agent and zinc as a reductant.⁶¹³ The selectivity of the *Gif* systems toward alkyl carbons is $\text{CH}_2 > \text{CH} \geq \text{CH}_3$, which is unusual, and shows that a simple free-radical mechanism (see p. 942) is not involved.⁶¹⁴ Another reagent that can oxidize the CH_2 of an alkane is methyl(trifluoromethyl)dioxirane, but this produces $\text{CH}-\text{OH}$ more often than $\text{C}=\text{O}$ (see **19-14**; **19-15**).⁶¹⁵ Simple unfunctionalized alkanes are oxidized to esters when treated with $\text{CBr}_4/2 \text{AlBr}_3$ and CO , but in very low yield.⁶¹⁶ Cyclic alkanes are oxidized to a mixture of the alcohol and the ketone with $\text{PhI}(\text{OAc})_2$ and a manganese complex in an ionic liquid.⁶¹⁷ Oxidation of cyclic alkanes to cyclic ketones was accomplished using a ruthenium catalyst.⁶¹⁸

19-18 Oxidation of Arylmethanes to Aldehydes

Oxo-de-dihydro-bisubstitution

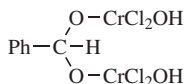

Methyl groups on an aromatic ring can be oxidized to the aldehyde stage by several oxidizing agents. The reaction is a special case of **19-17**. When the reagent is chromyl chloride (CrO_2Cl_2), the reaction is called the *Étard reaction*⁶¹⁹ and the yields are high.⁶²⁰ Another oxidizing agent is a mixture of CrO_3 and Ac_2O . In this case, the reaction stops at the aldehyde stage because the initial product is $\text{ArCH}(\text{OAc})_2$ (an acylal), which is resistant to further oxidation. Hydrolysis of the acylal gives the aldehyde.

Among other oxidizing agents⁶²¹ that have been used to accomplish the conversion of ArCH_3 to ArCHO are ceric ammonium nitrate,⁶²² ceric trifluoroacetate,⁶²³ hypervalent iodoso compounds (see **19-3**),⁶²⁴ urea- H_2O_2 with microwave irradiation,⁶²⁵ and silver(II) oxide.⁶²⁶ Oxidation of ArCH_3 to carboxylic acids is considered at **19-11**.

Conversion of ArCH_3 to ArCHO can also be achieved indirectly by bromination to give ArCHBr_2 (**14-1**), followed by hydrolysis (**10-2**).

The mechanism of the *Étard reaction* is not completely known.⁶²⁷ An insoluble complex is formed on addition of the reagents, which is hydrolyzed to the aldehyde. The complex is probably a kind of acylal, but the identity of the structure is not fully settled, although many proposals have been made as to its structure and as to how it is hydrolyzed.

35

It is known that ArCH_2Cl is not an intermediate (see **19-20**), since it reacts only very slowly with chromyl chloride. Magnetic susceptibility measurements⁶²⁸

⁶¹⁹The name *Étard reaction* is often applied to any oxidation with chromyl chloride, for example, oxidation of glycols (**19-7**), alkenes (**19-10**), and so on.

indicate that the complex from toluene is **35**, a structure first proposed by Étard. According to this proposal, the reaction stops after only two hydrogens have been replaced because of the insolubility of **35**. There is a disagreement on how **35** is formed, assuming that the complex has this structure. Both an ionic⁶²⁹ and a free-radical⁶³⁰ process have been proposed. An entirely different structure for the complex was proposed by Nenitzescu and co-workers.⁶³¹ On the basis of esr studies, they proposed that the complex is $\text{PhCH}_2\text{OCrCl}_2\text{OCrOCl}_2\text{OH}$, which is isomeric with **35**. However, this view has been challenged by Wiberg and Eisenthal,³³⁶ who interpret the esr result as being in accord with **35**. Still another proposal is that the complex is composed of benzaldehyde coordinated with reduced chromyl chloride.⁶³²

OS II, 441; III, 641; IV, 31, 713.

19-19 Oxidation of Aromatic Hydrocarbons to Quinones

Arene-quinone transformation

Condensed aromatic systems (including naphthalenes) can be directly oxidized to quinones by various oxidizing agents.^{258,633} Yields are generally not high, although good yields have been reported with ceric ammonium sulfate.⁶³⁴ Benzene cannot be so oxidized by strong oxidizing agents, but can be electrolytically oxidized to benzoquinone.⁶³⁵ Naphthalene derivatives, however, are oxidized to naphthoquinones with H_5IO_6 and CrO_3 .⁶³⁶ 1,4-Dimethoxy aromatic compounds are oxidized to para-quinones with an excess of CoF_3 in water-dioxane.⁶³⁷

19-20 Oxidation of Primary Halides and Esters of Primary Alcohols to Aldehydes⁶³⁸

Oxo-de-hydro, halo-bisubstitution

Primary alkyl halides (chlorides, bromides, and iodides) can be oxidized to aldehydes easily and in good yields with dimethyl sulfoxide,⁶³⁹ in what has been called the *Kornblum reaction*. In Kornblum's original work, the reaction of α -halo ketones with DMSO at elevated temperatures gave good yields of the corresponding glyoxal (an α -keto-aldehyde).⁶⁴⁰ If the glyoxal could be removed from the reaction medium by distillation as it was formed, the reaction was very efficient. In many cases, it was difficult to isolate high boiling glyoxals from DMSO. Primary and secondary⁶⁴¹ alkyl iodides or tosylates⁶⁴² can be converted to aldehydes or ketones, although they are much less reactive than α -halo ketones. Epoxides⁶⁴³ have been used to give α -hydroxy ketones or aldehydes.⁶⁴⁴ The reaction with tosyl esters is an indirect way of oxidizing primary alcohols to aldehydes (**19-3**). Primary chlorides with DMSO, NaBr, and ZnO give the corresponding aldehyde when heated to 140°C.⁶⁴⁵ Primary allylic bromides with a cyano group on the C=C unit are converted to conjugated α -cyano aldehydes with DMSO and NaHCO₃ at room temperature.⁶⁴⁶

⁶⁴⁶Ravichandran, S. *Synth. Commun.* **2001**, 31, 2185.

The mechanism of these DMSO oxidations is probably as follows:⁶⁴⁷

although in some cases the base abstracts a proton directly from the carbon being oxidized, in which case the ylid **37** is not an intermediate. Alkoxysulfonium salts (**36**) have been isolated.⁶⁴⁸ This mechanism predicts that secondary compounds should be oxidizable to ketones, and this is the case. In a related procedure for the oxidation of alcohols, the intermediate **36**⁶⁴⁹ is formed without the use of DMSO by treating the substrate with a complex generated from chlorine or NCS and dimethyl sulfide.⁶⁵⁰

Another way to oxidize primary alkyl halides to aldehydes is by the use of hexamethylenetetramine followed by water. However, this reaction, called the *Sommelet reaction*,⁶⁵¹ is limited to benzylic halides. The reaction is seldom useful when the R in RCH₂Cl is alkyl. The first part of the reaction is conversion to the amine ArCH₂NH₂, which can be isolated. Reaction of the amine with excess hexamethylenetetramine gives the aldehyde. It is this last step that is the actual Sommelet reaction, although the entire process can be conducted without isolation of intermediates. Once the amine is formed, it is converted to an imine (ArCH₂N=CH₂) with formaldehyde liberated from the reagent. The key step then follows: transfer of hydrogen from another mole of the arylamine to the imine. This last imine is then hydrolyzed by water to the aldehyde. Alternatively, the benzylamine may transfer hydrogen directly to hexamethylenetetramine. Another method that converts secondary bromides to ketones heads the bromide with NaIO₄ in DMF.⁶⁵²

Another reagent that convert benzylic halides to aldehydes is pyridine followed by *p*-nitrosodimethylaniline and then water, called the *Kröhnke reaction*. Primary halides and tosylates have been oxidized to aldehydes by trimethylamine *N*-oxide,⁶⁵³ and by pyridine *N*-oxide with microwave irradiation.⁶⁵⁴

19-21 Oxidation of Amines or Nitro Compounds to Aldehydes, Ketones, or Dihalides

Oxo-de-hydro, amino-bisubstitution (overall transformation)

Primary aliphatic amines can be oxidized to aldehydes or ketones.⁶⁵⁶ Other reagents used⁶⁵⁷ have been *N*-bromoacetamide⁶⁵⁸ (for benzylic amines), 3,5-di-*tert*-butyl-1,2-benzoquinone,⁶⁵⁹ and aqueous NaOCl with phase-transfer catalysts.⁶⁶⁰ Benzylic amine salts PhCHRNR'₂ H⁺ Cl⁻ (R, R' = H or alkyl) give benzaldehydes or aryl ketones when heated in DMSO.⁶⁶¹ Several indirect methods for achieving the conversion RR'CHNH₂ → RR'C=O (R' = alkyl, aryl, or H) have been reported.⁶⁶²

Primary, secondary, and tertiary aliphatic amines have been cleaved to give aldehydes, ketones, or carboxylic acids with aqueous bromine⁶⁶³ and with neutral permanganate.⁶⁶⁴ The other product of this reaction is the amine with one less alkyl group. In a different type of procedure, primary alkyl primary amines can be converted to *gem*-dihalides [RCH₂NH₂ → RCHX₂ (X = Br or Cl)] by treatment with an alkyl nitrite and the anhydrous copper(I) halide.⁶⁶⁵

Primary and secondary aliphatic nitro compounds have been oxidized to aldehydes and ketones, respectively (RR'CHNO₂ → RR'C=O) with sodium chlorite

under phase transfer conditions,⁶⁶⁶ tetrapropylammonium perruthenate (TPAP),⁶⁶⁷ Oxone[®],⁶⁶⁸ as well as with other reagents.⁶⁶⁹ Vinyl nitro compounds were converted to α -alkylated ketones, with good enantioselectivity, using R_2Zn , a chiral copper catalyst followed by hydrolysis with 20% aqueous sulfuric acid.⁶⁷⁰

19-22 Oxidation of Primary Alcohols to Carboxylic Acids or Carboxylic Esters

Oxo-de-dihydro-bisubstitution

Primary alcohols can be oxidized to carboxylic acids by many strong oxidizing agents including chromic acid, permanganate,⁶⁷¹ and nitric acid.⁶⁷² Other reagents include H_5IO_6/CrO_3 .⁶⁷³ The reaction can be looked on as a combination of **19-3** and **19-23**. When acidic conditions are used, a considerable amount of carboxylic ester $RCOOCH_2R$ is often isolated, although this is probably not formed by a combination of the acid with unreacted alcohol, but by a combination of intermediate aldehyde with unreacted alcohol to give an acetal or hemiacetal, which is oxidized to the ester.⁶⁷⁴ Aliphatic primary alcohols are converted to the carboxylic acid with 30% aq. H_2O_2 , tetrabutylammonium hydrogen sulfate and a tungsten catalyst with microwave irradiation.⁶⁷⁵ Oxone[®] in DMF also converts aliphatic aldehydes to the corresponding carboxylic acid.⁶⁷⁶ Benzylic alcohols are oxidized to benzoic acid derivatives by treatment first with TEMPO⁶⁷⁷ (p. 274), and then $NaClO_2$.⁶⁷⁸ A combination of $NaClO_2$ and NaH_2PO_4 in aq. DMSO oxidizes aldehydes to acids even in the presence of a disulfide

elsewhere in the molecule.⁶⁷⁹ Similar oxidation to the acid occurred with $\text{NaIO}_4/\text{RuCl}_3$ in aqueous acetonitrile,⁶⁸⁰ 30% aq. H_2O_2 , and a cobalt–salen catalyst,⁶⁸¹ or oxygen on alumina with microwave irradiation.⁶⁸² Aliphatic alcohols are converted to a symmetrical ester ($\text{RCH}_2\text{OH} \rightarrow \text{RCOOCH}_2\text{R}$) by oxidation with PCC on aluminum without solvent.⁶⁸³ Oxone in aqueous methanol also converts aryl aldehydes to the corresponding ester.⁶⁸⁴ Allylic alcohols are converted to conjugated esters with MnO_2 , NaCN in methanol–acetic acid.⁶⁸⁵ Primary alcohols are oxidized to the methyl ester with trichloroisocyanuric acid in methanol.⁶⁸⁶ This reagent also converts diols to lactones.

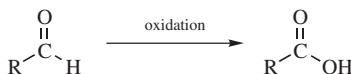

Primary alcohols RCH_2OH can be directly oxidized to acyl fluorides RCOF with cesium fluoroxysulfate.⁶⁸⁷ Lactones can be prepared by oxidizing diols in which at least one OH is primary,⁶⁸⁸ and addition of a chiral additive, such as sparteine, leads to lactones with high asymmetric induction.⁶⁸⁹ 2-(3-Hydroxypropyl)aniline was oxidized to an acyl derivative that cyclized to give a lactam when heated with a rhodium catalyst.⁶⁹⁰

Primary alkyl ethers can be selectively cleaved to carboxylic acids by aq. Br_2 ($\text{RCH}_2\text{OR}' \rightarrow \text{RCOOH}$).⁶⁹¹ Secondary allylic alcohols are converted to ketones with 70% *tert*-butylhydroperoxide with a CrO_3 catalyst.⁶⁹²

Oxidation of aldehydes-to-carboxylic acids is quite common⁶⁹³ and has been carried out with many oxidizing agents, the most popular of which is permanganate in acid, basic, or neutral solution.⁶⁹⁴ Chromic acid,⁶⁹⁵ bromine, and Oxone[®],⁶⁹⁶ are other reagents frequently employed. Bromate exchange resin in refluxing acetone oxidizes aryl aldehydes-to aryl-carboxylic acids.⁶⁹⁷ Silver oxide is a fairly specific oxidizing agent for aldehydes and does not readily attack other groups. Benedict's and Fehling's solutions oxidize aldehydes,⁶⁹⁸ and there is a test for aldehydes that depends on this reaction, but the method is seldom used for preparative purposes. In any case, it gives very poor results with aromatic aldehydes. α,β -Unsaturated aldehydes can be oxidized by sodium chlorite without disturbing the double bond.⁶⁹⁹ Aldehydes are also oxidized to carboxylic acids by atmospheric oxygen, but the actual direct oxidation product in this case is the peroxy acid RCO_3H ,⁷⁰⁰ which with another molecule of aldehyde, disproportionates to give two molecules of acid (see **14-7**).⁷⁰¹ Aryl aldehydes are converted to the corresponding aryl carboxylic ester with hydrogen peroxide and a V_2O_5 catalyst⁷⁰² or a titanosilicate⁷⁰³ in an alcohol solvent. Heating an α -bromoaldehyde with an alcohol and a triazolium carbene leads to the corresponding ester.⁷⁰⁴ *N*-Bromophthalimide and mercuric

acetate oxidizes aryl aldehydes to aryl carboxylic acids in chloroform at room temperature.⁷⁰⁵ An aldehyde can be converted to the carboxylic acid by treatment with 30% hydrogen peroxide and methyl(trioctyl)ammonium hydrogen sulfate at 90°C.⁷⁰⁶ Aryl aldehydes are similarly oxidized by a mixture of hydrogen peroxide and selenium dioxide (SeO₂).⁷⁰⁷ Aldehydes (RCHO) can be directly converted to carboxylic esters (RCOOR') by treatment with Br₂ in the presence of an alcohol.⁷⁰⁸ Polymer-bound hypervalent iodine + TEMPO oxidizes aldehydes to acids.⁷⁰⁹

Mechanisms of aldehyde oxidation⁷¹⁰ are not firmly established, but there seem to be at least two main types: a free-radical mechanism and an ionic one. In the free-radical process, the aldehydic hydrogen is abstracted to leave an acyl radical, which obtains OH from the oxidizing agent. In the ionic process, the first step is addition of a species ⁻OZ to the carbonyl bond to give **38** in alkaline solution and **39** in acid or neutral solution. The aldehydic hydrogen of **38** or **39** is then lost as a proton to a base, while Z leaves with its electron pair.

For oxidation with acid dichromate the picture seems to be quite complex, with several processes of both types going on:⁷¹¹

⁷¹¹Wiberg, K.B.; Szeimies, G. *J. Am. Chem. Soc.* **1974**, 96, 1889. See also, Roček, J.; Ng, C. *J. Am. Chem. Soc.* **1974**, 96, 1522, 2840; Sen Gupta, S.; Dey, S.; Sen Gupta, K.K. *Tetrahedron* **1990**, 46, 2431.

Steps 1 and 2 constitute an oxidation by the ionic pathway by Cr(VI), and steps 6 and 7 a similar oxidation by Cr(V), which is produced by an electron-transfer process. Either Cr(VI) (step 3) or Cr(IV) (step 4) [Cr(IV) is produced in step 2] may abstract a hydrogen and the resulting acyl radical is converted to carboxylic acid in step 5. Thus, chromium in three oxidation states is instrumental in oxidizing aldehydes. Still another possible process has been proposed in which the chromic acid ester decomposes as follows:⁷¹²

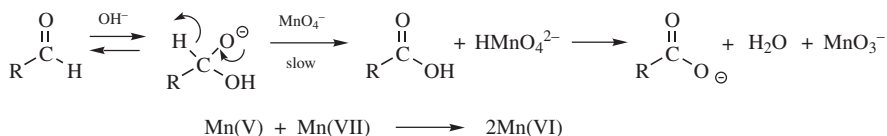

The mechanism with permanganate is less well known, but an ionic mechanism has been proposed⁷¹³ for neutral and acid permanganate, similar to steps 1 and 2 for dichromate:

⁷¹²See Roček, J.; Ng, C. *J. Org. Chem.* **1973**, *38*, 3348.

⁷¹³See, for example, Freeman, F.; Lin, D.K.; Moore, G.R. *J. Org. Chem.* **1982**, *47*, 56; Jain, A.L.; Banerji, K.K. *J. Chem. Res. (S)* **1983**, 60.

For alkaline permanganate, the following mechanism has been proposed:⁷¹⁴

OS I, 166; II, 302, 315, 538; III, 745; IV, 302, 493, 499, 919, 972, 974.

The conversion of thioketones to sulfines ($\text{R}_2\text{C}=\text{S}=\text{O}$) is difficult to categorize into the sections available, and it placed after oxidation of ketones and aldehydes. The reaction of a thioketone with hydrogen peroxide and a catalytic amount of MTO (methyl trioxorhenium) gives the sulfine.⁷¹⁵

19-24 Oxidation of Carboxylic Acids to Peroxy Acids

Peroxy-de-hydroxy-substitution

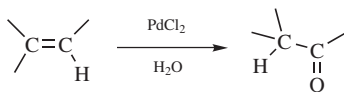

The oxidation of carboxylic acids with H_2O_2 and an acid catalyst is the best general method for the preparation of peroxy acids.⁷¹⁶ A mixture of $\text{Me}_2\text{C}(\text{OMe})\text{OOH}$ and DCC has also been used.⁷¹⁷ The most common catalyst for aliphatic R is concentrated sulfuric acid. The reaction is an equilibrium and is driven to the right by removal of water or by the use of excess reagents. For aromatic R, the best catalyst is methanesulfonic acid, which is also used as the solvent.

D. Reactions in Which Oxygen is Added to the Substrate

19-25 Oxidation of Alkenes to Aldehydes and Ketones

1/Oxo-(1/→2/hydro)-migr-attachment

Monosubstituted and 1,2-disubstituted alkenes can be oxidized to aldehydes and ketones by palladium chloride and similar salts of noble metals.⁷¹⁸ 1,1-Disubstituted alkenes generally give poor results. The reaction is used industrially to prepare acetaldehyde from ethylene (the *Wacker process*), but it is also suitable for laboratory preparations. The palladium chloride is reduced to palladium. Because the reagent is expensive, the reaction is usually carried out with a co-oxidant, most often CuCl_2 , whose function is to reoxidize the Pd to Pd(II). The CuCl_2 is reduced to Cu(I), which itself is reoxidized to Cu(II) by air, so that atmospheric oxygen is the only oxidizing agent actually used up. Many other co-oxidants have been tried, among them O_3 , Fe^{3+} , and PbO_2 . Terminal alkenes are oxidized to methyl ketones with O_2 and a palladium catalyst with 20% pyridine in *Z*-propanol.⁷¹⁹ *tert*-Butylhydroperoxide in bromoperfluorooctane–benzene oxidizes styrene to acetophenone in a Wacker-type process.⁷²⁰ The principal product is an aldehyde only from ethylene: With other alkenes Markovnikov's rule is followed, and ketones are formed predominantly.

The generally accepted mechanism involves π complexes of palladium.⁷²¹

This mechanism accounts for the fact, established by deuterium labeling, that the four hydrogens of the acetaldehyde all come from the original ethylene and none from the solvent.

Similar reactions have been carried out with other oxidizing agents. An example involving migration of an alkyl group instead of hydrogen is oxidation of $\text{Me}_2\text{C}=\text{CMe}_2$ with peroxytrifluoroacetic acid-boron trifluoride to give Me_3COME (pinacolone).⁷²² This reaction consists of epoxidation (**15-50**) followed by pinacol rearrangement of the epoxide (**18-2**). A migration is also involved in the conversion of $\text{ArCH}=\text{CHCH}_3$ to $\text{ArCH}(\text{CH}_3)\text{CHO}$ by treatment with $\text{I}_2\text{-Ag}_2\text{O}$ in aqueous dioxane.⁷²³

Other reagents used have been $\text{Pb}(\text{OAc})_4\text{-F}_3\text{CCOOH}$ ⁷²⁴ (e.g., $\text{PhCH}=\text{CH}_2 \rightarrow \text{PhCH}_2\text{CHO}$), H_2O_2 and a Pd catalyst,⁷²⁵ $\text{H}_2\text{O-PdCl}_2\text{-polyethylene glycol}$,⁷²⁶ $\text{CrO}_3\text{-H}_2\text{SO}_4\text{-Hg(II) salts}$,⁷²⁷ and $\text{Hg}(\text{OAc})_2$ followed by PdCl_2 .⁷²⁸ The reaction has also been accomplished electrochemically.⁷²⁹ Terminal alkenes react with ceric ammonium nitrate in methanol to give α -methoxy ketones.⁷³⁰

Alkenes have also been converted to more highly oxidized products. Examples are (1) treatment with KMnO_4 in aqueous acetone containing acetic acid gives α -hydroxy ketones.⁷³¹ (2) 1,2-Disubstituted and trisubstituted alkenes give α -chloro ketones when oxidized with chromyl chloride in acetone: $\text{RCH}=\text{CR}'\text{R}^2 \rightarrow \text{RCOCCIR}'\text{R}^2$.⁷³² (3) α -Iodo ketones can be prepared by treating alkenes with bis-(sym-collidine)iodine(I) tetrafluoroborate.⁷³³ (4) potassium permanganate in acetic anhydride oxidizes large-ring cycloalkenes to 1,2-diketones.⁷³⁴

Enol ethers are oxidized to carboxylic esters ($\text{RCH}=\text{CHOR}' \rightarrow \text{RCH}_2\text{COOR}'$) with PCC ⁷³⁵ and enamines to α -amino ketones ($\text{R}^1\text{CH}=\text{CR}_2\text{NR} \rightarrow \text{R}^1\text{COCR}_2\text{NR}$) with *N*-sulfonyloxaziridines.⁷³⁶ Enamines ($\text{R}^1\text{R}^4\text{C}=\text{CR}^2\text{NR}_3$, $\text{R}^4 \neq \text{H}$) do not give these products, but lose the amino group to give α -hydroxy ketones, $\text{R}^1\text{R}^4\text{C}(\text{OH})\text{-COR}^2$.⁷³⁶ Carboxylic acids can be prepared from terminal alkynes ($\text{RC}\equiv\text{CH} \rightarrow$

OS VI, 1028; VII, 137; VIII, 208.

19-26 The Oxidation of Alkynes to α-Diketones

Dioxo-biaddition

Internal alkynes have been oxidized⁷³⁸ to α-diketones by several oxidizing agents,⁷³⁹ including neutral KMnO₄,⁷⁴⁰ bis(trifluoroacetoxy)iodobenzene,⁷⁴¹ NaIO₄–RuO₂,⁷⁴² I₂–DMSO,⁷⁴³ MeReO₃/H₂O₂,⁷⁴⁴ as well as by electrooxidation.⁷⁴⁵ A ruthenium complex with a small amount of trifluoroacetic acid converts internal alkynes to the α-diketone.⁷⁴⁶ Ozone generally oxidizes triple-bond compounds to carboxylic acids (**19-9**), but α-diketones are sometimes obtained instead. Selenium dioxide (SeO₂) with a small amount of H₂SO₄ oxidizes alkynes to α-diketones as well as arylacetylenes to α-keto acids (ArC≡CH → ArCOCO₂H).⁷⁴⁷

Primary aromatic amines can be oxidized⁷⁴⁸ to nitroso compounds. Most often the conversion is accomplished by Caro's acid (H_2SO_5) or with H_2O_2 in HOAc.⁷⁴⁹ Hydroxylamines, which are probably intermediates in most cases, can sometimes be isolated, but under the reaction conditions are generally oxidized to the nitroso compounds. Primary aliphatic amines can be oxidized in this manner, but the nitroso compound is stable only if there is no α hydrogen. If there is an α hydrogen, the compound tautomerizes to the oxime.⁷⁵⁰ Among the reagents used for this oxidation are sodium perborate⁷⁵¹ H_2O_2 with a titanium complex,⁷⁵² HOF generated *in situ*,⁷⁵³ and $\text{Na}_2\text{WO}_4/\text{H}_2\text{O}_2$.⁷⁵⁴ The mechanism with H_2SO_5 has been postulated to be an example of category 5 (p. 1706).⁷⁵⁵

Secondary amines, R_2NH , are oxidized to hydroxylamines (R_2NHOH) which are resistant to further oxidation, by dimethyldioxirane⁷⁵⁶ and by benzoyl peroxide and Na_2HPO_4 .⁷⁵⁷ Oxone[®] on silica also oxidizes secondary alcohols to the hydroxylamine.⁷⁵⁸ Hydroxylamines are formed when secondary amines react with the enzyme cyclohexanone monooxygenase.⁷⁵⁹ Carbamates, such as *N*-Boc amines, are converted to the *N*-hydroxy compound with bis(trifluoromethyl)dioxirane.⁷⁶⁰ Note that secondary alcohols can be converted to nitrones with aq. H_2O_2 and a phosphotungstate polymer complex, presumably via a hydroxylamine (see **19-28**) formed *in situ*.⁷⁶¹ Dialkylamines are oxidized to the *N*-nitroso compound with N_2O_2 on polyvinylpyrrolidone.⁷⁶²

19-28 Oxidation of Primary Amines, Oximes, Azides, Isocyanates, or Nitroso Compounds to Nitro Compounds

Tertiary alkyl primary amines can be oxidized to nitro compounds in excellent yields with KMnO_4 .⁷⁶³ This type of nitro compound is not easily prepared in other ways. All classes of primary amine (including primary, secondary, and tertiary alkyl, as well as aryl) are oxidized to nitro compounds in high yields with dimethyldioxirane.⁷⁶⁴ Other reagents that oxidize various types of primary amines to nitro compounds are dry ozone,⁷⁶⁵ various peroxyacids,⁷⁶⁶ $\text{MeReO}_3/\text{H}_2\text{O}_2$,⁷⁶⁷ Oxone[®],⁷⁶⁸ *tert*-butyl hydroperoxide in the presence of certain molybdenum and vanadium compounds,⁷⁶⁹ and sodium perborate.⁷⁷⁰

Dimethyldioxirane in wet acetone oxidizes isocyanates to nitro compounds ($\text{RNCO} \rightarrow \text{RNO}_2$).⁷⁷¹ Oximes can be oxidized to nitro compounds with peroxytrifluoroacetic acid, or Oxone[®],⁷⁷² sodium perborate,⁷⁷³ among other ways.⁷⁶³ Secondary hydroxylamines are also oxidized to nitrones with MnO_2 in dichloromethane.⁷⁷⁴ Primary and secondary alkyl azides have been converted to nitro compounds by treatment with Ph_3P followed by ozone.⁷⁷⁵ Aromatic nitroso compounds are easily oxidized to nitro compounds by many oxidizing agents.⁷⁷⁶

19-29 Oxidation of Tertiary Amines to Amine Oxides

N-Oxygen-attachment

Tertiary amines can be converted to amine oxides by oxidation. Hydrogen peroxide is often used, but peroxyacids are also important reagents for this purpose. Pyridine and its derivatives are oxidized by peroxyacids⁷⁷⁷ rather than hydrogen peroxide. Note, however, that urea–H₂O₂ in formic acid does indeed oxidize pyridine.⁷⁷⁸ In the attack by hydrogen peroxide there is first formed a trialkylammonium peroxide, a hydrogen-bonded complex represented as R₃N•H₂O₂, which can be isolated.⁷⁷⁹ The decomposition of this complex probably involves an attack by the OH moiety of the H₂O₂. Oxidation with Caro's acid has been shown to proceed in this manner:⁷⁸⁰

This mechanism is the same as that of 19-27; the products differ only because tertiary amine oxides cannot be further oxidized. The mechanism with other peroxyacids is probably the same. A green procedure for oxidation of tertiary amines has been developed, using a Mg–Al complex with aq. hydrogen peroxide.⁷⁸¹

An alternative oxidation using O₂ and a RuCl₃ catalyst converted pyridine to pyridine *N*-oxide.⁷⁸² Bromamine-T and RuCl₃ in aq. acetonitrile also oxidizes pyridine to the *N*-oxide.⁷⁸³ Tertiary amines are oxidized to the *N*-oxide with O₂ and Fe₂O₃ in the presence of an aliphatic aldehyde.⁷⁸⁴ Oxygen and a cobalt–Schiff base complex also oxidizes tertiary amines, including pyridine.⁷⁸⁵

It is noted that azo compounds can be oxidized to azoxy compounds by peroxyacids⁷⁸⁶ or by hydroperoxides and molybdenum complexes.⁷⁸⁷

Analogous to the oxidation of tertiary amines, tertiary phosphines are oxidized to phosphine oxides, (R₃P=O). Triphenylphosphine is converted to triphenylphosphine

19-30 Oxidation of Thiols and Other Sulfur Compounds to Sulfonic Acids

Thiol-sulfonic acid oxidation

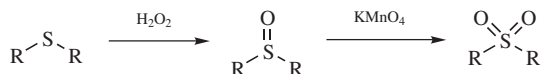

Thiols, sulfoxides, sulfones, disulfides,⁷⁹⁰ and other sulfur compounds can be oxidized to sulfonic acids with many oxidizing agents, but for synthetic purposes the reaction is most important for thiols.⁷⁹¹ Among oxidizing agents used are boiling nitric acid, barium permanganate, and dimethyl dioxirane.⁷⁹² Autoxidation (oxidation by atmospheric oxygen) can be accomplished in basic solution.⁷⁹³ Oxidation of thiols with chlorine and water gives sulfonyl chlorides directly.⁷⁹⁴ Thiols can also be oxidized to disulfides (19-34).

OS II, 471; III, 226. Also see, OS V, 1070.

19-31 Oxidation of Thioethers to Sulfoxides and Sulfones

S-Oxygen-attachment

Thioethers can be oxidized to sulfoxides by 1 equivalent of 30% H_2O_2 or by many other oxidizing agents,⁷⁹⁵ including H_2O_2 -flavin catalyst,⁷⁹⁶ H_2O_2 and a

oxidation to sulfoxides with an optically active reagent, and this has often been done.⁸²² In addition, the use of chiral additives in conjunction with various oxidizing agents leads to chiral nonracemic sulfoxide with good-to-excellent enantioselectivity.⁸²³ Asymmetric oxidation using bacterial monooxygenases is known,⁸²⁴ and horseradish peroxidase gives modest enantioselectivity.⁸²⁵ Chiral sulfur reagents are also known.⁸²⁶ Selenides (R_2Se) can be oxidized to selenoxides and selenones.⁸²⁷ It is possible to oxidize a thioether to a sulfoxide in the presence of an alcohol moiety using MnO_2/HCl .⁸²⁸ Alkyl disulfides give oxidation of one sulfur to give a $(RS-S(=O)R)$ compound with good enantioselectivity when using aqueous hydrogen peroxide, a catalytic amount of a vanadium catalyst and a chiral Schiff base ligand.⁸²⁹ *N*-Sulfonyloxaziridines can be used to oxidize sulfides to sulfoxides.⁸³⁰

When the oxidizing agent is a peroxide, the mechanism⁸³¹ of oxidation to the sulfoxide is similar to that of **19-29**.⁸³²

E. Oxidative Coupling

19-32 Coupling Involving Carbanions

De-hydro,chloro-coupling

Alkyl halides with an electron-withdrawing group on the halogen-bearing carbon can be dimerized to alkenes by treatment with bases. The Z group may be nitro, aryl, and so on. It is likely that in most cases the mechanism⁸³⁵ involves nucleophilic substitution followed by elimination⁸³⁶ (illustrated for benzyl chloride):

α,α -Dibromotoluenes (ArCHBr_2) give tolanes ($\text{ArC}\equiv\text{CAr}$), by debromination of the intermediates $\text{ArCBr}=\text{CBrAr}$.⁸³⁷ In a related reaction, diarylmethane dihalides

⁸³³There are some reagents that oxidize sulfoxides in preference to sulfides, for example, NaMnO_4 : see Henbest, H.B.; Khan, S.A. *Chem. Commun.* **1968**, 1036.

⁸³⁴Curci, R.; Di Furia, F.; Modena, G. *J. Chem. Soc. Perkin Trans. 2* **1978**, 603, and references cited therein. See also, Oae, S.; Takata, T. *Tetrahedron Lett.* **1980**, 21, 3213; Akasaka, T.; Ando, W. *J. Chem. Soc. Chem. Commun.* **1983**, 1203.

⁸³⁵For discussion, see Saunders, Jr., W.H.; Cockerill, A.F. *Mechanisms of Elimination Reactions*, Wiley, NY, **1973**, pp. 548–554.

⁸³⁶For example, see Hauser, C.R.; Brasen, W.R.; Skell, P.S.; Kantor, S.W.; Brodhag, A.E. *J. Am. Chem. Soc.* **1956**, 78, 1653; Hoeg, D.F.; Lusk, D.I. *J. Organomet. In some cases, a radical anion chain mechanism can take place: Bethell, D.; Bird, R. *J. Chem. Soc. Perkin Trans. 2* **1977**, 1856.

⁸³⁷Vernigor, E.M.; Shalaev, V.K.; Luk'yanets, E.A. *J. Org. Chem. USSR* **1981**, 17, 317.

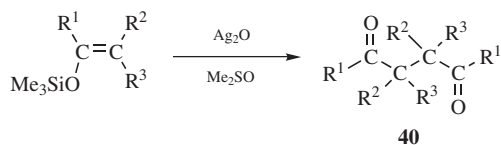

(Ar₂CX₂) have been dimerized to tetraaryl alkenes (Ar₂C=CAr₂) with copper,⁸³⁸ and with iron(II) oxalate dihydrate.⁸³⁹

A somewhat different type of coupling is observed when salts of β-keto esters, arylacetonitriles (ArCH₂CN), and other compounds of the form ZCH₂Z' are treated with an oxidizing agent, such as iodine,⁸⁴⁰ or Cu(II) salts.⁸⁴¹ Arylmethanesulfonyl chlorides (ArCH₂SO₂Cl) couple to give ArCH=CHAr when treated with Et₃N.⁸⁴²

OS II, 273; IV, 372, 869, 914; VIII, 298. Also see, OS I, 46; IV, 877.

19-33 Dimerization of Silyl Enol Ethers or of Lithium Enolates

3/O-De-trimethylsilyl-1/C-coupling

Silyl enol ethers can be dimerized to symmetrical 1,4-diketones by treatment with Ag₂O in DMSO or certain other polar aprotic solvents.⁸⁴³ The reaction has been performed with R², R³ = hydrogen or alkyl, although best yields are obtained when R² = R³ = H. In certain cases, unsymmetrical 1,4-diketones have been prepared by using a mixture of two silyl enol ethers. Other reagents that have been used to achieve either symmetrical or cross-coupled products are iodosobenzene–BF₃–Et₂O,⁸⁴⁴ ceric ammonium nitrate,⁸⁴⁵ and lead tetraacetate.⁸⁴⁶ If R¹ = OR (in which case the substrate is a ketene silyl acetal), dimerization with TiCl₄ leads to a dialkyl succinate (**40**, R¹ = OR).⁸⁴⁷

In a similar reaction, lithium enolates, RC(OLi)=CH₂, were dimerized to 1,4-diketones (RCOCH₂CH₂COR) with CuCl₂, FeCl₃, or copper(II) triflate, in a non-protic solvent.⁸⁴⁸

19-34 Oxidation of Thiols to Disulfides

S-De-hydrogen-coupling

Thiols are easily oxidized to disulfides.⁸⁴⁹ Hydrogen peroxide is the most common reagent,⁸⁵⁰ but many oxidizing agents give the reaction, among them $\text{KMnO}_4/\text{CuSO}_4$,⁸⁵¹ $\text{Me}_2\text{SO}-\text{I}_2$,⁸⁵² Br_2 under phase-transfer conditions,⁸⁵³ Br_2 on hydrated silica,⁸⁵⁴ sodium perborate,⁸⁵⁵ NaI/air ,⁸⁵⁶ $t\text{-BuOOH}/\text{VO}(\text{acac})_2$,⁸⁵⁷ SmI_2 ,⁸⁵⁸ PPh_3 with a rhodium catalyst,⁸⁵⁹ dibromohydantoin,⁸⁶⁰ cetyltrimethylammonium dichromate,⁸⁶¹ and NO . It can also be done electrochemically.⁸⁶² Hydrogen peroxide 30% in hexafluoroisopropanol converts thiols to disulfides,⁸⁶³ on Clayan with microwave irradiation,⁸⁶⁴ and solventless reactions on MnO_2 ,⁸⁶⁵ PCC (p. 1716)⁸⁶⁶ or SO_2Cl_2 ⁸⁶⁷ are also effective. However, strong oxidizing agents may give **19-26**. Even the oxygen in the air oxidizes thiols on standing, if a small amount of base is present. The reaction is reversible (see **19-75**), and the interconversion between cysteine and cystine is an important one in biochemistry.

⁸⁴⁹For a review, see Capozzi, G.; Modena, G., in Patai, S. *The Chemistry of the Thiol Group*, pt. 2, Wiley, NY, **1974**, pp. 785–839. For a list of reagents, with references, see Block, E. *Reactions of Organosulfur Compounds*, Academic Press, NY, **1978**.

⁸⁵⁰It has been pointed out that, nevertheless, H_2O_2 is not a very good reagent for this reaction, since it gives sulfonic acids (**19-30**) as well as disulfides: Evans, B.J.; Doi, J.T.; Musker, W.K. *J. Org. Chem.* **1990**, *55*, 2337.

The mechanism has been studied for several oxidizing agents and varies with the agent.⁸⁶⁸ For oxygen it is⁸⁶⁹

With respect to the sulfur, this mechanism is similar to that of **14-16**, involving as it does loss of a proton, oxidation to a free radical, and radical coupling.

Unsymmetrical disulfides can be prepared⁸⁷⁰ by treatment of a thiol RSH with diethyl azodicarboxylate EtOOCN=NCOOEt to give an adduct, to which another thiol R'SH is then added, producing the disulfide RSSR'.⁸⁷¹

OS **III**, 86, 116.

REDUCTIONS

For the most part, reductions have been grouped into this chapter, with a few notable exceptions. Catalytic hydrogenation of alkenes and alkynes in **15-11** and **15-12**, hydrogenation of aromatic rings in **15-13** and reductive cleavage of cyclopropanes in **15-15** were placed in Chapter 15 to coincide with addition reactions, and protonolysis of alkyl boranes in **15-16** was placed there also for continuity. In general, reductions of functional groups encompass a variety of reaction types. The reactions in this section are classified into groups depending on the type of bond change involved. These groups are (1) attack at carbon (C—O and C=O), (2) attack at non-carbonyl multiple bonds to heteroatoms, (3) reactions in which a heteroatom is removed from the substrate, (4) reduction with cleavage, (5) reductive coupling, and (6) reactions in which an organic substrate is both oxidized and reduced. Most of the reagents in this section are metal hydrides, metals with an acid or a protic solvent, hydrogen gas with a catalyst, and so on. Other reducing agents are available, and will be introduced in the appropriate section. Note that plants can be used as reducing agents.⁸⁷²

TABLE 19.2. The Ease of Reduction of Various Functional Groups Toward Catalytic Hydrogenation.⁸⁷⁶

Reaction	Substrate ^a	Product	
19-39	RCOCl	RCHO	Easiest
19-45	RNO ₂	RNH ₂	
15-11	RC≡CR	RCH=CHR	
19-36	RCHO	RCH ₂ OH	
15-11	RCH=CHR	RCH ₂ CH ₂ R	
19-36	RCOR	RCHOHR	
19-56	ArCH ₂ OR	ArCH ₃ + ROH	
19-43	RC≡N	RCH ₂ NH ₂	
15-14			
19-38	RCOOR'	RCH ₂ OH + R'OH	
19-64	RCOHNr'	RCH ₂ NHR	
15-13			Most difficult
19-37	RCOO ⁻		Inert

^aThe groups are listed in approximate order of ease of reduction.

Selectivity⁸⁷³

It is often necessary to reduce one group in a molecule without affecting another reducible group. It is usually possible to find a reducing agent that will do this. The most common broad-spectrum reducing agents are the metal hydrides⁸⁷⁴ and hydrogen (with a catalyst).⁸⁷⁵ Many different metal-hydride systems and hydrogenation catalysts have been investigated in order to find conditions under which a given group will be reduced chemoselectively. Tables 19.2–19.4 list the reactivity of various functional groups toward catalytic hydrogenation, LiAlH₄, and BH₃, respectively.⁸⁷⁶

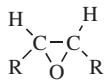

⁸⁷³For monographs on reductions in general, see Hudlický, M. *Reductions in Organic Chemistry*, Wiley, NY, **1984**; Augustine, R.L. *Reduction*, Marcel Dekker, NY, **1968**. For a review, see Candlin, J.P.; Rennie, R.A.C., in Bentley, K.W.; Kirby, G.W. *Elucidation of Chemical Structures by Physical and Chemical Methods* (Vol. 4 of Weissberger, A. *Techniques of Chemistry*), 2nd ed., pt. 2, Wiley, NY, **1973**, pp. 77–135.

⁸⁷⁴For discussions of selectivity with metal hydride reducing agents, see Brown, H.C.; Krishnamurthy, S. *Tetrahedron* **1979**, 35, 567; Walker, E.R.H. *Chem. Soc. Rev.* **1976**, 5, 23; Brown, H.C. *Boranes in Organic Chemistry*, Cornell University Press, Ithaca, NY, **1972**, pp. 209–251; Rerick, M.N., in Augustine, R.L. *Reduction*, Marcel Dekker, NY, **1968**. For books, see, in Ref. 10, the works by Seyden-Penne, J.; Strouf, O. et al., and Hajós, A.

⁸⁷⁵For a discussion of catalyst selectivity for hydrogenations, see Rylander, P.N. *Aldrichimica Acta* **1979**, 12, 53. See also, Rylander, P.N. *Hydrogenation Methods*, Academic Press, NY, **1985**.

⁸⁷⁶Table 19.2 is from House, H.O. *Modern Synthetic Reactions*, 2nd ed., W.A. Benjamin, NY, **1972**, p. 9. Tables 19.3 and 19.4 are from Brown, H.C. *Boranes in Organic Chemistry*, Cornell University Press, Ithaca, NY, **1972**, pp. 213 and 232, respectively.

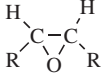

TABLE 19.3. The Ease of Reduction of Various Functional Groups with LiAlH₄ in Ether⁸⁷⁶

Reaction	Substrate ^a	Product	
19-36	RCHO	RCH ₂ OH	Easiest
19-36	RCOR	RCHOHR	
19-63	RCOCl	RCH ₂ OH	
19-38	Lactone	Diol	
19-35		RCH ₂ CHOHR	
19-38	RCOOR'	RCH ₂ OH + R'OH	
19-37	RCOOH	RCH ₂ OH	
19-37	RCOO ⁻	RCH ₂ OH	
19-64	RCONR' ₂	RCH ₂ NR' ₂	
19-43	RC≡N	RCH ₂ NH ₂	
19-45	RNO ₂	RNH ₂	
19-80	ArNO ₂	ArN=NAr	Most difficult
15-11	RCH=CHR ⁻		Inert

^aHowever, LiAlH₄ is a very powerful reagent, and much less chemoselectivity is possible here than with most of the other metal hydrides.

Table 19.5 shows which groups can be reduced by catalytic hydrogenation and various metal hydrides.⁸⁷⁷ Of course, the tables cannot be exact, because the nature of R and the reaction conditions obviously affect reactivity. Nevertheless, the tables do give a fairly good indication of which reagents reduce which

TABLE 19.4. The Ease of Reduction of Various Functional Groups With Borane⁸⁷⁶

Reaction	Substrate ^a	Product	
19-37	RCOOH	RCH ₂ OH	Easiest
15-16	RCH=CHR	(RCH ₂ CHR) ₃ B	
19-36	RCOR	RCHOHR	
19-43	RCN	RCH ₂ NH ₂	
19-35		RCH ₂ CHOHR	
19-38	RCOOR'	RCH ₂ OH + R'OH	Most difficult
19-39,19-63	RCOCl		Inert

^aIt is evident that this reagent and LiAlH₄ (Table 19.3) complement each other.

⁸⁷⁷The first 10 columns are from Brown, H.C.; Krishnamurthy, S. *Tetrahedron* **1979**, *35*, 567, p. 604. The column on (*i*-Bu)₂AlH is from Yoon, N.M.; Gyoung, Y.S. *J. Org. Chem.* **1985**, *50*, 2443; the one on NaAlEt₂H₂ from Stinson, S.R. *Chem. Eng. News*, Nov. 3, **1980**, *58*, No. 44, 19; and the one on LiBEt₃H from Brown, H.C.; Kim, S.C.; Krishnamurthy, S. *J. Org. Chem.* **1980**, *45*, 1. For similar tables that show additional reducing agents, see Pelter, A.; Smith, K.; Brown, H.C. *Borane Reagents*, Academic Press, NY, **1988**, p. 129; Hajós, A. *Complex Hydrides*, Elsevier, NY, **1979**, pp. 16–17. For tables showing which agents reduce a wide variety of functional groups, see Hudlický, M. *Reductions in Organic Chemistry*, Wiley, NY, **1984**, pp. 177–200.

groups.⁸⁷⁸ Lithium aluminium hydride is a very powerful and unselective reagent.⁸⁷⁹ Consequently, other metal hydrides are generally used when chemoselectivity is required. As will be seen on p. 1794, a number of less reactive (and more selective) reagents have been prepared by replacing some of the hydrogens of LiAlH_4 with alkoxy groups (by treatment of LiAlH_4 with ROH).⁸⁸⁰ Most of the metal hydrides are nucleophilic reagents and attack the carbon atom of a carbon-hetero single or multiple bond. Another useful reagent is LiAlHSeH .⁸⁸¹ However, BH_3 ^{882,883} and AlH_3 ⁸⁸⁴ are electrophiles (Lewis acids) and attack the heteroatom. This accounts for the different patterns of selectivity shown in the tables.

19-35 Reduction of Epoxides

(3) *OC-seco*-Hydro-de-alkoxylation

Reduction of epoxides is a special case of **19-56** and is easily carried out.⁸⁹¹ The most common reagent is LiAlH₄,⁸⁹² which reacts by the S_N2-type mechanism, giving inversion of configuration. An epoxide on a substituted cyclohexane ring cleaves in such a direction as to give an axial alcohol. As expected for an S_N2 mechanism, cleavage usually occurs so that a tertiary alcohol is formed if possible. If not, a secondary alcohol is preferred. However, for certain substrates, the epoxide ring can be opened the other way by reduction with NaBH₄-ZrCl₄,⁸⁹³ Pd/C and

⁸⁹⁰Reduced to hydroxylamine (**19-46**).

⁸⁹¹For a list of reagents, with references, see Larock, R.C. *Comprehensive Organic Transformations*, 2nd ed., Wiley-VCH, NY, **1999**, pp. 1019–1027.

⁸⁹²See Healy, E.F.; Lewis, J.D.; Minniear, A.B. *Tetrahedron Lett.* **1994**, 35, 6647 for a discussion of the LiAlH₄ reduction of unsaturated cyclic epoxides.

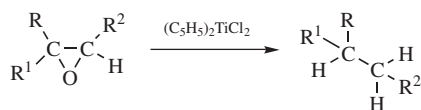

⁸⁹³Laxmi, Y.R.S.; Iyengar, D.S. *Synth. Commun.* **1997**, 27, 1731 (addition of L-proline to this reaction leads to moderate asymmetric induction).

HCOONH₄,⁸⁹⁴ SiO₂–Zn(BH₄)₂,⁸⁹⁵ or with BH₃ in THF.⁸⁹⁶ The reaction has also been carried out with other reagents, for example, sodium amalgam in EtOH, Li in ethylenediamine,⁸⁹⁷ Bu₃SnH–NaI,⁸⁹⁸ and by catalytic hydrogenolysis.⁸⁹⁹ Chemo-selective and regioselective ring opening (e.g., of allylic epoxides and of epoxy ketones and esters) has been achieved with SmI₂,⁹⁰⁰ HCOOH–NEt₃ and a palladium catalyst,⁹⁰¹ and sodium bis(2-methoxyethoxy)aluminum hydride (Red-Al).⁹⁰² Highly hindered epoxides can be conveniently reduced, without rearrangement, with lithium triethylborohydride.⁹⁰³

Epoxy ketones are selectively reduced with lithium naphthalenide⁹⁰⁴ or Cp₂TiCl in THF/MeOH⁹⁰⁵ to the β-hydroxyketone. Other reduction methods can lead to the epoxy alcohol (see p. \$\$\$). Reduction of epoxy amides with SmI₂ in methanol gave the α-hydroxyamide.⁹⁰⁶

Epi-sulfides can be reduced to give the alkene using Bu₃SnH in the presence of BEt₃.⁹⁰⁷

Epoxides can be reductively halogenated (the product is the alkyl bromide or iodide rather than the alcohol) with Me₃SiCl–NaX–(Me₂SiH)₂O (1,1,3,3-tetra-methyldisiloxane).⁹⁰⁸

The usual product of epoxide reductions is the alcohol, but epoxides are reduced all the way to the alkane by titanocene dichloride⁹⁰⁹ and by Et₃SiH–BH₃.⁹¹⁰

19-36 Reduction of Aldehydes and Ketones to Alcohols⁹¹¹**C,O-Dihydro-addition**

Aldehydes can be reduced to primary alcohols, and ketones to secondary alcohols, by a number of reducing agents,⁹¹² of which LiAlH₄ and other metallic hydrides are the most commonly used.⁹¹³ These reagents have two main advantages over many other reducing agents: They do not reduce carbon-carbon double or triple bonds (with the exception of propargylic alcohols),⁹¹⁴ and with LiAlH₄ all four hydrogens are usable for reduction. The reaction is broad and general. Lithium aluminum hydride easily reduces aliphatic, aromatic, alicyclic, and heterocyclic aldehydes, containing double or triple bonds and/or nonreducible groups, such as NR₃, OH, OR, and F. If the molecule contains a group reducible by LiAlH₄ (e.g., NO₂, CN, COOR), then it is also reduced. Since LiAlH₄ reacts readily with water and alcohols, these compounds must be excluded. Common solvents are ether and THF. The compound NaBH₄ has a similar scope, but is more selective and so may be used with NO₂, Cl, COOR, CN, and so on in the molecule. Another advantage of NaBH₄ is that it can be used in water or alcoholic solvents and so reduces compounds, such as sugars that are not soluble in ethers.⁹¹⁵ Other solvents can be used with some modification of the borohydride. For example, butyltriphenylphosphonium borohydride reduces aldehydes to alcohols in dichloromethane.⁹¹⁶ A polymer-bound phase-transfer material with NaBH₄ in wet THF has also been used.⁹¹⁷ Sodium borohydride on alumina, under microwave irradiation, is also an effective reagent.⁹¹⁸ Sodium borohydride has been used on silica gel.⁹¹⁹ The scope of these reagents with ketones is similar to that with aldehydes. Lithium aluminum hydride reduces even sterically hindered ketones.

The double bonds that are generally not affected by metallic hydrides may be isolated or conjugated, but double bonds that are conjugated with the C=O group may or may not be reduced, depending on the substrate, reagent, and reaction conditions.⁹²⁰ Some reagents that reduce only the C=O bonds of α,β -unsaturated aldehydes and ketones are AlH_3 ,⁹²¹ NaBH_4 , or LiAlH_4 in the presence of lanthanide salts,⁹²² cobalt complexes,⁹²³ nickel compounds,⁹²⁴ I_2 ,⁹²⁵ $\text{NaBH}_3(\text{OAc})$,⁹²⁶ $\text{Zn}(\text{BH}_4)_2$ ⁹²⁷ on Y-zeolite,⁹²⁸ and Et_3SiH .⁹²⁹ Also, both LiAlH_4 ⁹³⁰ and NaBH_4 ⁹³¹ predominantly reduce only the C=O bonds of C=C–C=O systems in most cases, although substantial amounts of fully saturated alcohols have been found in some cases⁹³⁰ (15-14). For some reagents that reduce only the C=C bonds of conjugated aldehydes and ketones, see 15-11. A mixture of InCl_3 and NaBH_4 reduced both the C=C and C=O units of conjugated ketones.⁹³²

When a functional group is selectively attacked in the presence of a different functional group, the reaction is said to be *chemoselective*.⁹³³ A number of reagents have been found to reduce aldehydes much faster than ketones. Among these⁹³⁴ are sodium triacetoxyborohydride⁹³⁵ ($\text{NaBH}_4\text{--HCOOH}$),⁹³⁶ zinc borohydride in THF,⁹³⁷ bis-(isopropoxytitanium borohydride),⁹³⁸ a complex of LiAlH_4 and *N*-methyl-2-pyrrolidinone (of particular interest since it is stable in air and to heating),⁹³⁹ and Raney nickel.⁹⁴⁰ On

the other hand, ketones can be chemoselectively reduced in the presence of aldehydes with NaBH_4 in aq. EtOH at -15°C in the presence of cerium trichloride CeCl_3 .⁹⁴¹ The reagent lithium *n*-dihydropyridylaluminum hydride reduces diaryl ketones much better than dialkyl or alkyl aryl ketones.⁹⁴² Most other hydrides reduce diaryl ketones more slowly than other types of ketones. Saturated ketones can be reduced in the presence of α,β -unsaturated ketones with NaBH_4 -50% MeOH- CH_2Cl_2 at -78°C ⁹⁴³ and with zinc borohydride.⁹⁴⁴

In general, NaBH_4 reduces carbonyl compounds in this order: aldehydes $>$ α,β -unsaturated aldehydes $>$ ketones $>$ α,β -unsaturated ketones, and a carbonyl group of one type can be selectively reduced in the presence of a carbonyl group of a less reactive type.⁹⁴⁵ A number of reagents will preferentially reduce the less sterically hindered of two carbonyl compounds, but by the use of DIBALH in the presence of the Lewis acid methylaluminum bis(2,16-di-*tert*-butyl-4-methylphenoxide), it was possible selectively to reduce the *more hindered* of a mixture of two ketones.⁹⁴⁶ It is obvious that reagents can often be found to reduce one kind of carbonyl function in the presence of another.⁹⁴⁷ For a discussion of selectivity in reduction reactions, see p. 1787. A syn-selective reduction of β -hydroxy ketones was achieved using $(i\text{PrO})_2\text{TlBH}_4$.⁹⁴⁸

Quinones are reduced to hydroquinones by LiAlH_4 , SnCl_2 -HCl, or sodium hydrosulfite ($\text{Na}_2\text{S}_2\text{O}_4$), as well as by other reducing agents.

The reagent lithium tri-*sec*-butylborohydride $\text{LiBH}(\text{sec-Bu})_3$ (L-Selectride) reduces cyclic and bicyclic ketones in a highly stereoselective manner.⁹⁴⁹ For example, 2-methylcyclohexanone gave *cis*-2-methylcyclohexanol with an isomeric purity $>99\%$. Both L-Selectride and the potassium salt (κ -Selectride) reduce carbonyls in cyclic and acyclic molecules with high diastereoselectivity.⁹⁵⁰ The more usual reagents, for example, LiAlH_4 , NaBH_4 , reduce relatively unhindered cyclic ketones either with little or no stereoselectivity⁹⁵¹ or give predominant formation of the more stable isomer (axial attack).⁹⁵² Mixed reagents, such as

⁹⁴¹See Gemal, A.L.; Luche, J. *Tetrahedron Lett.* **1981**, 22, 4077; Li, K.; Hamann, L.G.; Koreeda, M. *Tetrahedron Lett.* **1992**, 33, 6569.

For a review of stereoselective synthesis of amino alcohols by this method, see Tramontini, M. *Synthesis* **1982**, 605.

⁹⁵²For a discussion of why this isomer is predominantly formed, see Mukherjee, D.; Wu, Y.; Fronczek, F.R.; Houk, K.N. *J. Am. Chem. Soc.* **1988**, 110, 3328.

$\text{LiBH}_3[\text{N}(\text{C}_2\text{H}_5)_2]$, gives high selectivity for axial attack.⁹⁵³ Reduction of cyclohexanone derivatives with the very hindered $\text{LiAlH}(\text{C}_2\text{H}_5)_2\text{CMe}_3$ gave primarily the cis-alcohol.⁹⁵⁴ Cyclohexanones that have a large degree of steric hindrance near the carbonyl group usually give predominant formation of the less stable alcohol, even with LiAlH_4 and NaBH_4 .

Other reagents reduce aldehydes and ketones to alcohols,⁹⁵⁵ including:

1. *Hydrogen and a Catalyst.*⁹⁵⁶ The most common catalysts are platinum and ruthenium, but homogeneous catalysts have also been used,⁹⁵⁷ including copper on silica gel⁹⁵⁸ and a ruthenium catalyst on mesoporous silica.⁹⁵⁹ Before the discovery of the metal hydrides this was one of the most common ways of effecting this reduction, but it suffers from the fact that $\text{C}=\text{C}$, $\text{C}\equiv\text{C}$, $\text{C}=\text{N}$, and $\text{C}\equiv\text{N}$ bonds are more susceptible to attack than $\text{C}=\text{O}$ bonds.⁹⁶⁰ For aromatic aldehydes and ketones, reduction to the hydrocarbon (**19-61**) is a side reaction, stemming from hydrogenolysis of the alcohol initially produced (**19-54**).
2. *Sodium in Ethanol.*⁹⁶¹ This is called the *Bouveault–Blanc procedure* and was more popular for the reduction of carboxylic esters (**19-38**) than of aldehydes or ketones before the discovery of LiAlH_4 .

For the reaction with sodium in ethanol the following mechanism⁹⁶² has been suggested:⁹⁶³

⁹⁵³Harrison, J.; Fuller, J.C.; Goralski, C.T.; Singaram, B. *Tetrahedron Lett.* **1994**, 35, 5201.

⁹⁵⁴Boireau, G.; Deberly, A.; Toneva, R. *Synlett* **1993**, 585. In this study, reduction with $\text{LiAlH}(\text{O}i\text{-Bu})_3$ was shown to give primarily the trans-alcohol.

⁹⁵⁵This can also be done electrochemically. For a review, see Feoktistov, L.G.; Lund, H., in Baizer, M.M.; Lund, H. *Organic Electrochemistry*, Marcel Dekker, NY, **1983**, pp. 315–358, 315–326. See also, Coche, L.; Moutet, J. *J. Am. Chem. Soc.* **1987**, 109, 6887.

Chem. Soc. Perkin Trans. 2* **1989**, 269. For a review of the stereochemistry of these reactions in liquid NH_3 , see Rassat, A. *Pure Appl. Chem.* **1977**, 49, 1049.

⁹⁶³House, H.O. *Modern Synthetic Reactions*, 2nd ed., W.A. Benjamin, NY, **1972**, p. 151. See, however, Giordano, C.; Perdoncin, G.; Castaldi, G. *Angew. Chem. Int. Ed.* **1985**, 24, 499.

The ketyl intermediate can be isolated.⁹⁶⁴

3. *Isopropyl Alcohol and Aluminum Isopropoxide*. This is called the *Meerwein-Ponndorf-Verley reduction*.⁹⁶⁵ It is reversible, and the reverse reaction is known as the *Oppenauer oxidation* (see 19-3):

The equilibrium is shifted by removal of the acetone by distillation. There is a report of the reduction of benzaldehyde to benzyl alcohol by heating with Z-propanol at 225°C for 1 day.⁹⁶⁶ The reaction takes place under very mild conditions and is highly specific for aldehydes and ketones, so that C=C bonds (including those conjugated with the C=O bonds) and many other functional groups can be present without themselves being reduced.⁹⁶⁷ This includes acetals, so that one of two carbonyl groups in a molecule can be specifically reduced if the other is first converted to an acetal. β-Keto esters, β-diketones, and other ketones and aldehydes with a relatively high enol content do not give this reaction. A SmI₃-assisted version of this reduction has been reported.⁹⁶⁸ Zeolites have been used as a medium for this reduction.⁹⁶⁹ This reduction can be done catalytically⁹⁷⁰ and an aluminum-free, zirconium zeolite catalyst has been developed.⁹⁷¹ A combination of Z-propanol with BINOL and AlMe₃ leads to reduction of α-chloroketones to the chlorohydrin with good enantioselectivity.⁹⁷² Microwave irradiation of a ketone with Z-propanol, KOH, and activated alumina gives good yields of the alcohol.⁹⁷³

⁹⁶⁴For example, see Rautenstrauch, V.; Geoffroy, M. *J. Am. Chem. Soc.* **1976**, *98*, 5035; **1977**, *99*, 6280.

⁹⁶⁵For other catalysts, see Akamanchi, K.G.; Noorani, V.R. *Tetrahedron Lett.* **1995**, *36*, 5085; Akamanchi, K.G.; Varalakshmy, N.R. *Tetrahedron Lett.* **1995**, *36*, 3571; Maruoka, K.; Saito, S.; Concepcion, A.B.; Yamamoto, H. *J. Am. Chem. Soc.* **1993**, *115*, 1183. For a microwave-induced version of this reaction, see Barbry, D.; Torchy, S. *Tetrahedron Lett.* **1997**, *38*, 2959.

⁹⁶⁶Bagnell, L.; Strauss, C.R. *Chem. Commun.* **1999**, 287.

⁹⁶⁷Diisobornyloxyaluminum isopropoxide gives higher yields under milder conditions than aluminum isopropoxide: Hutton, J. *Synth. Commun.* **1979**, *9*, 483. For other substitutes for aluminum isopropoxide, see Namy, J.L.; Soupe, J.; Collin, J.; Kagan, H.B. *J. Org. Chem.* **1984**, *49*, 2045; Okano, T.; Matsuoka, M.; Konishi, H.; Kiji, J. *Chem. Lett.* **1987**, 181.

⁹⁷²Campbell, E.J.; Zhou, H.; Nguyen, S.T. *Angew. Chem. Int. Ed.* **2002**, *41*, 1020.

⁹⁷³Kazemi, F.; Kiasat, A.R. *Synth. Commun.* **2002**, *32*, 2255.

The Meerwein–Ponndorf–Verley reaction usually⁹⁷⁴ involves a cyclic transition state:⁹⁷⁵

but in some cases 2 equivalents of aluminum alkoxide are involved: one attacking the carbon and the other the oxygen, a conclusion that stems from the finding that in these cases the reaction was 1.5 order in alkoxide.⁹⁷⁶ Although, for simplicity, we have shown the alkoxide as a monomer, it actually exists as trimers and tetramers, and it is these that react.⁹⁷⁷

4. *Metal Reductions.* A single carbonyl group of an α -diketone can be reduced (to give an α -hydroxy ketone) by heating with zinc powder in aq. DMF⁹⁷⁸ or zinc in methanol in the presence of benzyltriethylammonium chloride.⁹⁷⁹ This has also been accomplished with aq. VCl_2 ⁹⁸⁰ and with $\text{Zn-ZnCl}_2\text{-EtOH}$.⁹⁸¹ Aluminum and NaOH in aqueous methanol reduces ketones.⁹⁸² β -Hydroxy ketones are reduced with good anti-selectivity using an excess of SmI_2 in water,⁹⁸³ and other ketones or aldehydes are reduced with SmI_2 ⁹⁸⁴ in aq. THF,⁹⁸⁵ in *Z*-propanol,⁹⁸⁶ or methanol.⁹⁸⁷ Other metals can be used, including FeCl_3/Zn in aq. DMF⁹⁸⁸ or DME/MeOH.⁹⁸⁹ 1,2-Diketones were reduced to the α -hydroxy ketone with TiI_4 in acetonitrile, followed by hydrolysis.⁹⁹⁰ Ammonia and aq. TiCl_3 in methanol reduces ketones.⁹⁹¹

⁹⁷⁴It has been that shown in some cases reduction with metal alkoxides, including aluminum isopropoxide, involves free-radical intermediates (SET mechanism): Screttas, C.G.; Cazianis, C.T. *Tetrahedron* **1978**, *34*, 933; Nasipuri, D.; Gupta, M.D.; Banerjee, S. *Tetrahedron Lett.* **1984**, *25*, 5551; Ashby, E.C.; Argyropoulos, J.N. *J. 5. *Boranes*. Borane (BH₃) and substituted boranes reduce aldehydes and ketones in a manner similar to their addition to C=C bonds (**15-16**).⁹⁹² That is, the boron adds to the oxygen and the hydrogen to the carbon:⁹⁹³

The borate is then hydrolyzed to the alcohol. Both 9-BBN⁹⁹⁴ (p. 1077) and BH₃-Me₂S⁹⁹⁵ reduce only the C=O group of conjugated aldehydes and ketones. A variety of alkylboranes can be used for reduction.⁹⁹⁶ Borane reduction of a titanium complex of a 1,3-diketone gives the syn-diol.⁹⁹⁷ Reduction occurs with B₁₀H₁₄ with CeCl₃,⁹⁹⁸ Alane (AlH₃) derivatives can also be used, including diisobutylaluminum hydride.⁹⁹⁹ Tributylborane in ionic solvents reduces aldehydes to alcohols.¹⁰⁰⁰

6. *Tin Hydrides*. Tributyltin hydride reduces aldehydes to primary alcohols by simply heating in methanol.¹⁰⁰¹ A mixture of Bu₃SnH and phenylboronic acid (p. 815) reduces aldehydes in dichloromethane.¹⁰⁰² Reduction of ketones was achieved with Bu₂SnH₂ and a palladium catalyst.¹⁰⁰³ Using triaryltin hydrides with BF₃·OEt₂, where aryl is 2,6-diphenylbenzyl, selective reduction of aliphatic aldehydes in the presence of a conjugated aldehyde was achieved.¹⁰⁰⁴
7. *Cannizzaro Reaction*. In the Cannizzaro reaction (**19-81**), aldehydes without an α hydrogen are reduced to alcohols.
8. *Silanes*. In the presence of bases, certain silanes can selectively reduce carbonyls. Epoxy-ketones are reduced to epoxy-alcohols, for example, with

(MeO)₃SiH and LiOMe.¹⁰⁰⁵ Controlling temperature and solvent leads to different ratios of syn- and anti- products.¹⁰⁰⁶ Silanes reduce ketones in the presence of BF₃•OEt₂¹⁰⁰⁷ and transition-metal compounds catalyze this reduction.¹⁰⁰⁸ Ketones are reduced with Cl₃SiH in the presence of pyrrolidine carboxaldehyde¹⁰⁰⁹ or under photochemical conditions.¹⁰¹⁰ Polymethylhydrosiloxane with tetrabutylammonium fluoride reduces α-amino ketones to give the syn-amino alcohol.¹⁰¹¹

9. *Ammonium Formates*. Sodium formate and trialkylammonium formates can be used to reduce aldehydes and ketones to the corresponding alcohol. Decanal was reduced to decanol, for example, using sodium formate in *N*-methyl-2-pyrrolidinone as a solvent.¹⁰¹² A mixture of formic acid and ethyl magnesium bromide was used to reduce decanal to decanol in 70% yield.¹⁰¹³

Unsymmetrical ketones are prochiral (p. 193); that is, reduction creates a new stereogenic center:

Much effort has been put into finding optically active reducing agents that will produce one enantiomer of the alcohol enantioselectively, and considerable success has been achieved.¹⁰¹⁴ Each reagent tends to show a specificity for certain types of ketones.¹⁰¹⁵ H.C. Brown and co-workers¹⁰¹⁶ reduced various types of ketone with a number of reducing agents. These workers also determined the relative effectiveness of various reagents for reduction of eight other types of ketone, including heterocyclic, aralkyl, β-keto esters, β-keto acids,¹⁰¹⁷ and so on.¹⁰¹⁶ In most cases, good enantioselectivity can be obtained with the proper reagent.¹⁰¹⁸ Substituents that are

dendritic chiral catalyst has been used in conjunction with borane,¹⁰³⁴ as well as other chiral additives can be used.¹⁰³⁵

A third important method is the combination of LiAlH_4 or NaBH_4 with a chiral ligand, often in the presence of a transition-metal complex.¹⁰³⁶ Examples include $\text{LiBH}_4/\text{NiCl}_2$ and a chiral amino alcohol,¹⁰³⁷ NaBH_4 with chiral Lewis acid complexes,¹⁰³⁸ or $\text{NaBH}_4/\text{Me}_3\text{SiCl}$ and a chiral ligand.¹⁰³⁹ A mixture of NaBH_4 and Me_3SiCl with a catalytic amount of a chiral, polymer-bound sulfonamide leads to asymmetric reduction.¹⁰⁴⁰

Enantioselective reduction is possible with the other methods mentioned above. Reduction with silanes and transition-metal catalysts, such as ruthenium compounds, is also very effective.¹⁰⁴¹ This method gives high enantioselectivity with various types of ketone, especially α,β -unsaturated ketones. Chiral ruthenium catalysts have been used with triethylammonium formate for the enantioselective reduction.¹⁰⁴² A ruthenium catalyst with a polymer-supported chiral ligand has been used with Bu_4NBr and HCO_2Na in water.¹⁰⁴³ Chiral additives mixed with surfactants have been used with sodium formate.¹⁰⁴⁴ Enantioselective reduction was observed with PhSiH_3 and copper compounds with a chiral ligand,¹⁰⁴⁵ with a mixture of ruthenium and silver catalysts,¹⁰⁴⁶ or with $\text{Mn}(\text{dpm})_3$ and oxygen ($\text{dpm} = \text{diphenylmethylene}$).¹⁰⁴⁷ Asymmetric reduction was achieved using an

alkoxide or hydroxide base with a chiral rhodium,¹⁰⁴⁸ ruthenium,¹⁰⁴⁹ or iridium complex.¹⁰⁵⁰ A chiral samarium complex has been used in conjunction with Z-propanol.¹⁰⁵¹ Chiral mercapto alcohols have also been used for asymmetric reduction.¹⁰⁵²

Enantioselective reduction is not possible for aldehydes, since the products are primary alcohols in which the reduced carbon is not chiral, but deuterated aldehydes RCDO give a chiral product, and these have been reduced enantioselectively with B-(3-pinanyl)-9-borabicyclo[3.3.1]nonane (Alpine-Borane) with almost complete optical purity.¹⁰⁵³ Other chiral boranes can be used to reduce aldehydes or ketones.¹⁰⁵⁴

In the above cases, an optically active reducing agent or catalyst interacts with a prochiral substrate. Asymmetric reduction of ketones has also been achieved with an achiral reducing agent, if the ketone is complexed to an optically active transition-metal Lewis acid.¹⁰⁵⁵

There are other stereochemical aspects to the reduction of aldehydes and ketones. If there is a stereogenic center α to the carbonyl group,¹⁰⁵⁶ even an achiral reducing agent can give more of one diastereomer than of the other. Such

¹⁰⁵⁶In theory, the chiral center can be anywhere in the molecule, but in practice, reasonable diastereoselectivity is most often achieved when it is in the α position. For examples of high diastereoselectivity when the chiral center is further away, especially in reduction of β -hydroxy ketones, see Narasaka, K.; Pai, F. *Tetrahedron* **1984**, *40*, 2233; Hassine, B.B.; Gorsane, M.; Pecher, J.; Martin, R.H. *Bull. Soc. Chim. Belg.* **1985**, *94*, 597; Bloch, R.; Gilbert, L.; Girard, C. *Tetrahedron Lett.* **1988**, *53*, 1021; Evans, D.A.; Chapman, K.T.; Carreira, E.M. *J. Am. Chem. Soc.* **1988**, *110*, 3560.

diastereoselective reductions have been carried out with considerable success.¹⁰⁵⁷ In most such cases Cram's rule (p. 168) is followed, but exceptions are known.¹⁰⁵⁸

With most reagents there is an initial attack on the carbon of the carbonyl group by a hydride equivalent (H^-) although with BH_3 ¹⁰⁵⁹ the initial attack is on the oxygen. Detailed mechanisms are not known in most cases.¹⁰⁶⁰ With tetrahydroaluminum or borohydride compounds, the attacking species is the AlH_4^- (or BH_4^-) ion, which, in effect, transfers H^- to the carbon. The following mechanism has been proposed for LiAlH_4 :¹⁰⁶¹

Evidence that the cation plays an essential role, at least in some cases, is that when the Li^+ was effectively removed from LiAlH_4 (by the addition of a crown ether), the reaction did not take place.¹⁰⁶² The complex **42** must now be hydrolyzed to the alcohol. For NaBH_4 , the Na^+ does not seem to participate in the transition state, but kinetic evidence shows that an OR group from the solvent does participate and remains attached to the boron:¹⁰⁶³

Free H^- cannot be the attacking entity in most reductions with boron or aluminum hydrides because the reactions are frequently sensitive to the size of the MH_4^- [or MR_mH_n^- or $\text{M}(\text{OR})_m\text{H}_n^-$ etc.].

¹⁰⁵⁷For reviews, see N6gr6di, M. *Stereoselective Synthesis*, VCH, NY, **1986**, pp. 131–148; Oishi, T.; Nakata, T. *Acc. Chem. Res.* **1984**, *17*, 338.

¹⁰⁵⁸One study showed that the Cram's rule product predominates with metal hydride reducing agents, but the other product with Bouveault-Blanc and dissolving metal reductions: Yamamoto, Y.; Matsuoka, K.; Nemoto, H. *J. Am. Chem. Soc.* **1988**, *110*, 4475.

The question of whether the initial complex in the LiAlH_4 reduction (**42**, which can be written as $\text{H}-\overset{\text{R}}{\underset{\text{R}}{\text{C}}}-\overset{\ominus}{\text{O}}\overset{\oplus}{\text{Al}}\text{H}_3 = \mathbf{43}$) can reduce another carbonyl to give $\text{H}-\overset{\text{R}}{\underset{\text{R}}{\text{C}}}-\overset{\ominus}{\text{O}}_2\overset{\oplus}{\text{Al}}\text{H}_4$ and so on has been controversial. It has been shown¹⁰⁶⁴ that this is probably not the case but that, more likely, **43** disproportionates to $(\text{H}-\overset{\text{R}}{\underset{\text{R}}{\text{C}}}-\overset{\ominus}{\text{O}})_4\overset{\oplus}{\text{Al}}$ and AlH_4^- , which is the only attacking species. Disproportionation has also been reported in the NaBH_4 reaction.¹⁰⁶⁵

Aluminate, **43**, is essentially LiAlH_4 with one of the hydrogens replaced by an alkoxy group, that is, LiAlH_3OR . The fact that **43** and other alkoxy derivatives of LiAlH_4 are less reactive than LiAlH_4 itself has led to the use of such compounds as reducing agents that are less reactive and more selective than LiAlH_4 .¹⁰⁶⁶ We have already met some of these, for example, $\text{LiAlH}(\text{O}-t\text{-Bu})_3$ (reactions **19-39-19-41**; see also, Table 19.5). As an example of chemoselectivity in this reaction it may be mentioned that $\text{LiAlH}(\text{O}-t\text{-Bu})_3$ has been used to reduce only the keto group in a molecule containing both keto and carboxylic ester groups.¹⁰⁶⁷ However, the use of such reagents is sometimes complicated by the disproportionation mentioned above, which may cause LiAlH_4 to be the active species, even if the reagent is an alkoxy derivative. Another highly selective reagent (reducing aldehydes and ketones, but not other functional groups), which does not disproportionate, is potassium triisopropoxyborohydride.¹⁰⁶⁸

The mechanism of catalytic hydrogenation of aldehydes and ketones is probably similar to that of reaction **15-11**, although not much is known about it.¹⁰⁶⁹

Carboxylic acids are easily reduced to primary alcohols by LiAlH_4 .¹⁰⁷⁰ The reaction does not stop at the aldehyde stage (but see **19-40**). The conditions are particularly mild, the reduction proceeding quite well at room temperature. Other hydrides have also been used,¹⁰⁷¹ but not NaBH_4 (see Table 19.5).¹⁰⁷² Note, however, that complexation of the carboxylic acid with cyanuric chloride (2,4,6-trichlorotriazine) also smooth reduction to the alcohol.¹⁰⁷³ A combination of NaBH_4 and an arylboronic acid (p. 815) is also effective.¹⁰⁷⁴ Benzyltriethylammonium borohydride is dichloromethane also reduces carboxylic acids to the alcohol.¹⁰⁷⁵ Catalytic hydrogenation is also generally ineffective.¹⁰⁷⁶ Borane is particularly good for carboxyl groups (Table 19.4) and permits selective reduction of them in the presence of many other groups (although the reaction with double bonds takes place at about the same rate in ether solvents).¹⁰⁷⁷ Borane also reduces carboxylic acid salts.¹⁰⁷⁸ Aluminum hydride reduces COOH groups without affecting carbon-halogen bonds in the same molecule. The reduction has also been carried out with SmI_2 in basic media¹⁰⁷⁹ or aq. H_3PO_4 ,¹⁰⁸⁰ or simply with SmI_2 in water.¹⁰⁸¹ A mixture of NaBH_4 and I_2 has been used to reduced amino acids to amino alcohols.¹⁰⁸²

Lithium aluminum hydride reduces carboxylic esters to give 2 equivalents of alcohol.¹⁰⁸³ The reaction is of wide scope and has been used to reduce many esters. Where the interest is in obtaining R'OH, this is a method that is often a working equivalent of "hydrolyzing" esters. Lactones yield diols. Among the reagents that give the same products¹⁰⁸⁴ are DIBALH, lithium triethylborohydride, LiAlH(Ot-Bu)₃,¹⁰⁸⁵ and BH₃–SMe₂ in refluxing THF.¹⁰⁸⁶ Although NaBH₄ reduces phenolic esters, especially those containing electron-withdrawing groups,¹⁰⁸⁷ its reaction with other esters is usually so slow that it is not the reagent of choice (exceptions are known¹⁰⁸⁸), and it is generally possible to reduce an aldehyde or ketone without reducing an ester function in the same molecule. Note that NaBH₄ in DMF–MeOH reduces aryl carboxylic esters to benzylic alcohols,¹⁰⁸⁹ and NaBH₄–LiCl with microwave irradiation also reduces esters to primary alcohols.¹⁰⁹⁰ However, NaBH₄ reduces esters in the presence of certain compounds (see Table 19.5).¹⁰⁹¹ Carboxylic esters can also be reduced to alcohols by hydrogenation over copper chromite catalysts,¹⁰⁹² although high pressures and temperatures are required. Ester functions generally survive low-pressure catalytic hydrogenations. Before the discovery of LiAlH₄, the most common way of carrying out the reaction was with sodium in ethanol, a method known as the *Bouveault–Blanc procedure*. This procedure is still sometimes used where selectivity is necessary (see also, **19-62**, **19-65**, and **19-59**).

Silanes, such as Ph₂SiH₂, with a catalytic amount of triphenylphosphine and a rhodium catalyst reduced esters to primary alcohols.¹⁰⁹³ Aliphatic silanes such as EtMe₂SiH, also reduced esters with a ruthenium catalyst.¹⁰⁹⁴

19-39 Reduction of Acyl Halides

Hydro-de-halogenation or Dehalogenation

Acyl halides can be reduced to aldehydes¹⁰⁹⁵ by treatment with lithium *tert*-butoxyaluminum hydride in diglyme at -78°C .¹⁰⁹⁶ The R group may be alkyl or aryl and may contain many types of substituents, including NO_2 , CN, and EtOOC groups. The reaction stops at the aldehyde stage because steric hindrance prevents further reduction under these conditions. Acyl halides can also be reduced to aldehydes by hydrogenolysis with palladium-on-barium sulfate as catalyst. This is called the *Rosenmund reduction*.¹⁰⁹⁷ A more convenient hydrogenolysis procedure involves palladium-on-charcoal as the catalyst, with ethyldiisopropylamine as acceptor of the liberated HCl and acetone as the solvent.¹⁰⁹⁸ The reduction of acyl halides to aldehydes has also been carried out¹⁰⁹⁹ with Bu_3SnH ,¹¹⁰⁰ with the InCl_3 -catalyzed reaction with Bu_3SnH ,¹¹⁰¹ with NaBH_4 in a mixture of DMF and THF,¹¹⁰² and with formic acid/ NH_4OH .¹¹⁰³ In some of these cases, the mechanisms are free-radical. There are several indirect methods for the conversion of acyl halides to aldehydes, most of them involving prior conversion of the halides to certain types of amides (see **19-41**). There is also a method in which the COOH group is replaced by a completely different CHO group (**16-87**).

19-40 Reduction of Carboxylic Acids, Esters, and Anhydrides to Aldehydes¹¹⁰⁴**Hydro-de-hydroxylation or Dehydroxylation** (overall transformation)

With most reducing agents, reduction of carboxylic acids generally gives the primary alcohol (**19-37**) and the isolation of aldehydes is not feasible. However, simple straight-chain carboxylic acids have been reduced to aldehydes¹¹⁰⁵ by treatment with Li in MeNH₂ or NH₃ followed by hydrolysis of the resulting imine,¹¹⁰⁶ with

with hexylchloro(or bromo)borane-Me₂S¹¹⁰⁷ (see **15-16** for the hexyl group), Me₂N=CHCl⁺ Cl⁻ in pyridine,¹¹⁰⁸ and with diaminoaluminum hydrides.¹¹⁰⁹ Benzoic acid derivatives were reduced to benzaldehyde derivatives with NaH₂PO₂ and a diacylperoxide and a palladium catalyst.¹¹¹⁰ Caproic and isovaleric acids have been reduced to aldehydes in 50% yields or better with DIBALH (*i*-Bu₂AlH) at -75 to -70°C.¹¹¹¹ Carboxylic acids can be reduced directly on Claycop-H₂O₂ using microwave irradiation.¹¹¹²

Carboxylic esters have been reduced to aldehydes with DIBALH at -70°C, with diaminoaluminum hydrides,¹¹¹³ with LiAlH₄-Et₂NH,¹¹¹⁴ and for phenolic esters with LiAlH(O-*t*-Bu)₃ at 0°C.¹¹¹⁵ Aldehydes have also been prepared by reducing ethyl thiol esters (RCOSET) with Et₃SiH and a Pd-C catalyst.¹¹¹⁶ Pretreatment of

the acid with Me_3SiCl followed by reduction with DIBALH also gives the aldehyde.¹¹¹⁷ Thioesters have been reduced to the aldehyde with lithium metal in THF at -78°C , followed by quenching with methanol.¹¹¹⁸

Anhydrides, both aliphatic and aromatic, as well as mixed anhydrides of carboxylic and carbonic acids, have been reduced to aldehydes in moderate yields with disodium tetracarbonylferrate, $\text{Na}_2\text{Fe}(\text{CO})_4$.¹¹¹⁹ Heating a carboxylic acid, presumably to form the anhydride, and then reaction with Na/EtOH leads to the aldehyde.¹¹²⁰

Acid chlorides are reduced to aldehydes with Bu_3SnH and a nickel catalyst.¹¹²¹

Also see, **19-62** and **19-38**.

OS VI, 312; VIII, 241, 498.

19-41 Reduction of Amides to Aldehydes

Hydro-de-dialkylamino-substitution

N,N-Disubstituted amides can be reduced to amines with LiAlH_4 (see **19-64**), but also to aldehydes.¹¹²² Keeping the amide in excess gives the aldehyde rather than the amine. Sometimes it is not possible to prevent further reduction and primary alcohols are obtained instead. Other reagents¹¹²³ that give good yields of aldehydes are DIBALH,¹¹²⁴ $\text{LiAlH}(\text{O}-t\text{-Bu})_3$, diaminoaluminum hydrides,¹¹²⁵ disiamylborane (see **15-16** for the disiamyl group),¹¹²⁶ and $\text{Cp}_2\text{Zr}(\text{H})\text{Cl}$.¹¹²⁷

Aldehydes have been prepared from carboxylic acids or acyl halides by first converting them to certain types of amides that are easily reducible. There are several examples:¹¹²⁸

reduce nitriles except in alcoholic solvents with a catalyst, such as CoCl_2 ,¹¹⁶⁸ NiCl_2 ,¹¹⁶⁹ or Raney nickel.¹¹⁷⁰ A mixture of $\text{NaBH}_4/\text{NiCl}_2$ in acetic anhydride reduces the nitrile to the amine, which is trapped as the acetamide.¹¹⁷¹ Lithium dimethylamino-borohydride ($\text{LiBH}_3\text{NMe}_2$) reduces aryl nitriles to the corresponding benzylamines.¹¹⁷²

The reduction of nitriles is of wide scope and has been applied to many nitriles. When catalytic hydrogenation is used, secondary amines, $(\text{RCH}_2)_2\text{NH}$, are often side products.¹¹⁷³ These can be avoided by adding a compound, such as acetic anhydride, which removes the primary amine as soon as it is formed,¹¹⁷⁴ or by the use of excess ammonia to drive the equilibria backward.¹¹⁷⁵ Sponge nickel¹¹⁷⁶ or nickel on silica gel¹¹⁷⁷ have been used for the catalytic hydrogenation of aryl nitriles to amines.

Attempts to stop with the addition with only 1 equivalent of hydrogen, have failed that is, to convert the nitrile to an imine, except where the imine is subsequently hydrolyzed (**19-44**).

N-Alkylnitrium ions are reduced to secondary amines by NaBH_4 .¹¹⁷⁸

Since nitrium salts can be prepared by treatment of nitriles with trialkyl-oxonium salts (see **16-8**), this is a method for the conversion of nitriles to secondary amines.

Note that the related compounds, the isocyanides ($\text{R}-\text{N}\equiv\text{C}^\ominus$, also called isocyanides) have been reduced to *N*-methylamines with LiAlH_4 , as well as with other reducing agents.

19-44 The Reduction of Nitriles to Aldehydes**Hydro,oxy-de-nitrilo-tersubstitution**

There are two principal methods for the reduction of nitriles to aldehydes.¹¹⁷⁹ In one of these, known as the *Stephen reduction*, the nitrile is treated with HCl to form an iminium salt, **47**.

Iminium salt **47** is reduced with anhydrous SnCl₂ to RCH=NH, which precipitates as a complex with SnCl₄ and is then hydrolyzed (**16-2**) to the aldehyde. The Stephen reduction is most successful when R is aromatic, but it can be done for aliphatic R up to about six carbons.¹¹⁸⁰ It is also possible to prepare **47** in a different way, by treating ArCONHPh with PCl₅, which can then be converted to the aldehyde. This is known as the *Sonn-Müller method*. Aqueous formic acid in the presence of PtO₂, followed by treatment with aqueous acid, converts aryl nitriles to aryl aldehydes.¹¹⁸¹

The other way of reducing nitriles to aldehydes involves using a metal hydride reducing agent to add 1 equivalent of hydrogen and hydrolysis, *in situ*, of the resulting imine (which is undoubtedly coordinated to the metal). This has been carried out with LiAlH₄, LiAlH(OEt)₃,¹¹⁸² LiAlH(NR₂)₃,¹¹⁸³ and DIBALH.¹¹⁸⁴ The metal hydride method is useful for aliphatic and aromatic nitriles.

OS III, 626, 818; VI, 631.

19-45 Reduction of Nitro Compounds to Amines

Both aliphatic¹¹⁸⁵ and aromatic nitro compounds can be reduced to amines, although the reaction has been applied much more often to aromatic nitro

compounds, owing to their greater availability. Many reducing agents have been used to reduce aromatic nitro compounds, the most common being Zn, Sn, or Fe (or sometimes other metals) and acid, and catalytic hydrogenation.¹¹⁸⁶ Indium metal in aqueous ethanol with ammonium chloride¹¹⁸⁷ or with water in aq. THF¹¹⁸⁸ also reduces aromatic nitro compounds to the corresponding aniline derivative. Indium metal in methanol, with acetic anhydride and acetic acid, converts aromatic nitro compounds to the acetanilide.¹¹⁸⁹ Samarium and a catalytic amount of iodine also accomplishes this reduction,¹¹⁹⁰ as does Sm with a bipyridinium dibromide in methanol.¹¹⁹¹ Samarium metal in methanol with ultrasound also reduces aryl nitro compounds.¹¹⁹² Sodium sulfide (NaHS) on alumina with microwave irradiation reduces aryl nitro compounds to aniline derivatives.¹¹⁹³ A mild reduction uses Al(Hg) in aq. THF with ultrasound.¹¹⁹⁴ An Al/NiCl₂ reagent was used to reduce the nitro group of a polymer-bound CH₂OCH₂C₆H₄NO₂ moiety.¹¹⁹⁵ Some other reagents used¹¹⁹⁶ were Et₃SiH/RhCl(PPh₃)₃,¹¹⁹⁷ AlH₃-AlCl₃, Mn with CrCl₂,¹¹⁹⁸ nanoparticulate iron in water at 210°C,¹¹⁹⁹ formic acid and Pd-C¹²⁰⁰ for formic acid with Raney nickel in methanol,¹²⁰¹ and sulfides, such as NaHS, (NH₄)₂S, or polysulfides. The reaction with sulfides or polysulfides is called the *Zinin reduction*.¹²⁰² Amines are also the products when nitro compounds, both alkyl and aryl, are reduced with HCOONH₄-Pd-C.¹²⁰³ Many other functional groups (e.g., COOH, COOR, CN, amide) are not affected by this reagent (although ketones are reduced, see 19-33). With optically active alkyl substrates this method gives

retention of configuration.¹²⁰⁴ Ammonium formate in methanol reduces aromatic nitro compounds.¹²⁰⁵ Lithium aluminum hydride reduces aliphatic nitro compounds to amines, but with aromatic nitro compounds the products with this reagent are azo compounds (**19-80**). Most metal hydrides, including NaBH_4 and BH_3 , do not reduce nitro groups at all, although both aliphatic and aromatic nitro compounds have been reduced to amines with NaBH_4 and various catalysts, such as NiCl_2 or CoCl_2 ¹²⁰⁶ phthalocyanine iron (II),¹²⁰⁷ and ZrCl_4 .¹²⁰⁸ Borohydride exchange resin in the presence of $\text{Ni}(\text{OAc})_2$, however, gives the amine.¹²⁰⁹ Treatment of aromatic nitro compounds with NaBH_4 alone has resulted in reduction of the *ring* to a cyclohexane ring with the nitro group still intact¹²¹⁰ or in cleavage of the nitro group from the ring.¹²¹¹ With $(\text{NH}_4)_2\text{S}$ or other sulfides or polysulfides it is often possible to reduce just one of two or three nitro groups on an aromatic ring or on two different rings in one molecule.¹²¹² The nitro groups of *N*-nitro compounds can also be reduced to amino groups, for example, nitrourea $\text{NH}_2\text{CONHNO}_2$ gives semicarbazide $\text{NH}_2\text{CONHNH}_2$. Bakers yeast reduces aromatic nitro compounds to aniline derivatives.¹²¹³ A combination of $\text{NaH}_2\text{PO}_2/\text{FeSO}_4$ with microwave irradiation reduces aromatic nitro compounds to aniline derivatives.¹²¹⁴ Hydrazine on alumina, with FeCl_3 and microwave irradiation accomplishes this reduction.¹²¹⁵ Hydrazine–formic acid with Raney nickel in methanol reduces aromatic nitro compounds.¹²¹⁶ Heating aromatic nitro compounds with 57% HI reduces the nitro group to the amino group.¹²¹⁷

With some reducing agents, especially with aromatic nitro compounds, the reduction can be stopped at an intermediate stage, and hydroxylamines (**19-46**), hydrazobenzenes, azobenzenes (**19-80**), and azoxybenzenes (**19-79**) can be obtained in this manner. However, nitroso compounds, which are often postulated as intermediates, are too reactive to be isolated, if indeed they are intermediates. Reduction by metals in mineral acids cannot be stopped, but always produces the amine.

The mechanisms of these reductions have not been studied much, although it is usually presumed that, at least with some reducing agents, nitroso compounds and hydroxylamines are intermediates. Both of these types of compounds give amines when exposed to most of these reducing agents (19-47), and hydroxylamines can be isolated (19-46). With metals and acid the following path has been suggested:¹²¹⁸

Certain aromatic nitroso compounds (Ar-NO) can be obtained in good yields by irradiation of the corresponding nitro compounds in 0.1 *M* aq. KCN with uv light.¹²¹⁹ The reaction has also been performed electrochemically.¹²²⁰ When nitro compounds are treated with most reducing agents, nitroso compounds are either not formed or react further under the reaction conditions and cannot be isolated.

Reductive alkylation of aromatic nitro compounds is possible. The reaction of nitrobenzene with allylic or benzyl halides in the presence of an excess of tin metal in methanol, leads to the *N,N*-diallyl or dibenzyl aniline.¹²²¹ A similar reaction occurs with nitrobenzene, allyl bromide, and indium metal in aq. acetonitrile.¹²²²

purpose have been SmI_2 ,¹²²⁴ $\text{N}_2\text{H}_4\text{-Rh-C}$,¹²²⁵ and $\text{KBH}_4/\text{BiCl}_3$.¹²²⁶ Borane in THF reduces aliphatic nitro enolate anions to hydroxylamines:¹²²⁷

Nitro compounds have been reduced electrochemically, to hydroxylamines, as well as to other products.¹²²⁸

OS I, 445; III, 668; IV, 148; VI, 803; VIII, 16.

19-47 Reduction of Nitroso Compounds and Hydroxylamines to Amines

N-Dihydro-de-oxo-bisubstitution

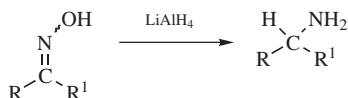

N-Hydro-de-hydroxylation or *N*-Dehydroxylation

Nitroso compounds and hydroxylamines can be reduced to amines by the same reagents that reduce nitro compounds (19-45). Reaction with CuCl , and then phenylboronic acid (p. 815), also reduces nitroso compounds to the amine.¹²²⁹ A hydroxylamine can be reduced to the amine with CS_2 in acetonitrile.¹²³⁰ Indium metal in $\text{EtOH/aq. NH}_4\text{Cl}$ reduces hydroxylamines to the amine.¹²³¹ *N*-Nitroso compounds are similarly reduced to hydrazines $\text{R}_2\text{N-NO} \rightarrow \text{R}_2\text{N-NH}_2$.¹²³²

¹²³¹Cicchì, S.; Bonanni, M.; Cardona, F.; Revuelta, J.; Goti, A. *Org. Lett.* **2003**, 5, 1773.

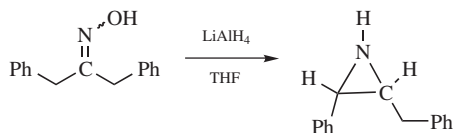

¹²³²For examples of this reduction, accomplished with titanium reagents, see Entwistle, I.D.; Johnstone, R.A.W.; Wilby, A.H. *Tetrahedron* **1982**, 38, 419; Lunn, G.; Sansone, E.B.; Keefer, L.K. *J. Org. Chem.* **1984**, 49, 3470.

Both aldoximes and ketoximes can be reduced to primary amines with LiAlH_4 . The reaction is slower than with ketones, so that, for example, $\text{PhCOCH}=\text{NOH}$ gave 34% $\text{PhCHOHCH}=\text{NOH}$.¹²³³ Among other reducing agents that give this reduction¹²³⁴ are zinc and acetic acid, BH_3 ,¹²³⁵ $\text{NaBH}_3\text{CN}-\text{TiCl}_3$,¹²³⁶ polymethylhydrosiloxane (PMHS) with $\text{Pd}-\text{C}$,¹²³⁷ and sodium and an alcohol.¹²³⁸ Catalytic hydrogenation is also effective.¹²³⁹ The reduction has been performed enantioselectively with Baker's yeast¹²⁴⁰ and with Ph_2SiH_2 and an optically active rhodium complex catalyst.¹²⁴¹ Reduction of oximes with indium metal in acetic anhydride/acetic acid-THF leads to the acetamide.¹²⁴² Oxime *O*-ethers are reduced to the amine with modest enantioselectivity using a chiral oxazaboroline.¹²⁴³

When the reducing agent is DIBALH, the product is a secondary amine, arising from a rearrangement:¹²⁴⁴

With certain oximes (e.g., those of the type $\text{ArCH}_2\text{CR}=\text{NOH}$), treatment with LiAlH_4 gives aziridines,¹²⁴⁵ for example,

Hydrazones, arylhydrazones, and semicarbazones can also be reduced to amines with various reducing agents, including $\text{Zn}-\text{HCl}$ and H_2 and Raney nickel.

Oximes have been reduced in a different way, to give imines ($RR'C=NOH \rightarrow RR'C=NH$), which are generally unstable but which can be trapped to give useful products. Among reagents used for this purpose have been Bu_3P-SPh_2 ¹²⁴⁶ and $Ru_3(CO)_{12}$.¹²⁴⁷ Oximes can also be reduced to hydroxylamines (**19-42**). Nitrones have been reduced to imines using $AlCl_3 \cdot 6 H_2O/KI$ followed by $Na_2S_2O_3-H_2O$.¹²⁴⁸

OS II, 318; III, 513; V, 32, 83, 373, 376.

19-49 Reduction of Aliphatic Nitro Compounds to Oximes or Nitriles

Nitro compounds that contain an α hydrogen can be reduced to oximes with zinc dust in acetic acid¹²⁴⁹ or with other reagents, among them CS_2-NEt_3 ,¹²⁵⁰ $CrCl_2$,¹²⁵¹ and (for α -nitro sulfones) $NaNO_2$.¹²⁵² α -Nitro alkenes have been converted to oximes

with sodium hypophosphite, indium with aq. $NH_4Cl/MeOH$,¹²⁵³ and with $Pb-HOAc-DMF$, as well as with certain other reagents.¹²⁵⁴

Primary aliphatic nitro compounds can be reduced to aliphatic nitriles with sodium dihydro(trithio)borate¹⁰⁸⁷ or with $t-BuN\equiv C/BuN=C=O$.¹²⁵⁵ Secondary compounds give mostly ketones (e.g., nitrocyclohexane gave 45% cyclohexanone, 30% cyclohexanone oxime, and 19% *N*-cyclohexylhydroxylamine). Tertiary aliphatic nitro compounds do not react with this reagent (see also, **19-45**).

19-50 Reduction of Azides to Primary Amines

N-Dihydro-de-diazo-bisubstitution

Azides are easily reduced to primary amines by LiAlH_4 , as well as by a number of other reducing agents,¹²⁵⁶ including NaBH_4 , $\text{NaBH}_4/\text{LiCl}$,¹²⁵⁷ $\text{NaBH}_4/\text{CoCl}_2/\text{H}_2\text{O}$,¹²⁵⁸ $\text{NaBH}_4/\text{ZrCl}_4$,¹²⁵⁹ $\text{BHCl}_2 \cdot \text{SMe}_2$,¹²⁶⁰ H_2 and a catalyst, $\text{Bu}_3\text{SnH}/\text{PhSiH}_3/\text{AIBN}$,¹²⁶¹ Mg or Ca in MeOH ,¹²⁶² Sm/NiCl_2 ,¹²⁶³ $\text{Zn}-\text{FeCl}_3/\text{EtOH}$,¹²⁶⁴ $\text{Zn}/\text{NH}_4\text{Cl}/\text{aq. EtOH}$,¹²⁶⁵ FeCl_3/NaI ,¹²⁶⁶ $\text{FeSO}_4/\text{NH}_3/\text{MeOH}$,¹²⁶⁷ baker's yeast,¹²⁶⁸ Sm/I_2 ,¹²⁶⁹ Indium metal in EtOH ,¹²⁷⁰ $\text{LiMe}_2\text{NBH}_3$,¹²⁷¹ and tin complexes prepared from SnCl_2 or $\text{Sn}(\text{SR})_2$.¹²⁷² Reaction with PPh_3 leads to a phosphazide, $\text{Ph}_3\text{P}=\text{N}-\text{N}=\text{N}-\text{R}$, which loses nitrogen in what is called the *Staudinger reaction*¹²⁷³ a method to prepare phosphazo compounds, but in this case leads to reduction. Alkylation is possible, and the reaction of an alkyl azide with PMe_3 , and then an excess of iodomethane leads to the *N*-methylated amine.¹²⁷⁴ This reaction, combined with $\text{RX} \rightarrow \text{RN}_3$ (**10-43**), is an important way of converting alkyl halides RX to primary amines RNH_2 ; in some cases the two procedures have been combined into one laboratory step.¹²⁷⁵ Sulfonyl azides RSO_2N_3

have been reduced to sulfonamides RSO_2NH_2 by irradiation in isopropyl alcohol¹²⁷⁶ and with NaH .¹²⁷⁷

OS V, 586; VII, 433.

19-51 Reduction of Miscellaneous Nitrogen Compounds

Isocyanates and isothiocyanates are reduced to methylamines on treatment with LiAlH_4 . LiAlH_4 does not usually reduce azo compounds¹²⁷⁸ (indeed these are the products from LiAlH_4 reduction of nitro compounds, **19-80**), but these can be reduced to hydrazo compounds by catalytic hydrogenation or with diimide¹²⁷⁹ (see **15-11**). Diazonium salts are reduced to hydrazines by sodium sulfite. This reaction probably has a nucleophilic mechanism.¹²⁸⁰

The initial product is a salt of hydrazinesulfonic acid, which is converted to the hydrazine by acid treatment. Diazonium salts can also be reduced to arenes (**19-69**). *N*-Nitrosoamines can be denitrosated to secondary amines by a number of reducing agents, including H_2 and a catalyst,¹²⁸¹ $\text{BF}_3\text{-THF-NaHCO}_3$,¹²⁸² and $\text{NaBH}_4\text{-TiCl}_4$,¹²⁸³ as well as by hydrolysis.¹²⁸⁴

A cyano group can be reduced to a methyl group by treatment with a terpene, such as limonene (which acts as reducing agent) in the presence of palladium-charcoal.¹²⁸⁵ Hydrogen gas (H_2) is also effective,¹²⁸⁶ although higher temperatures are required. The group R may be alkyl or aryl. Cyano groups CN have also been reduced to CH_2OH , in the vapor phase, with 2-propanol and zirconium oxide.¹²⁸⁷

Aryl nitro compounds are reduced to diaryl hydrazines with Al-KOH in methanol.¹²⁸⁸

OS I, 442; III, 475. Also see, OS V, 43.

C. Reactions in Which a Heteroatom Is Removed from the Substrate

19-52 Reduction of Silanes to Methylene Compounds

Si-Hydrogen-uncoupling

In certain cases, the C—Si bond of silanes can be converted to C—H. α -Silyl esters are reduced to esters with mercuric acetate and tetrabutylammonium fluoride, for example.¹²⁸⁹

19-53 Reduction of Alkyl Halides

Hydro-de-halogenation or Dehalogenation

This type of reduction can be accomplished with many reducing agents.¹²⁹⁰ A powerful, but highly useful reagent is LiAlH_4 ,¹²⁹¹ which reduces almost all types of

alkyl halide, including vinylic, bridgehead, and cyclopropyl halides.¹²⁹² Reduction with lithium aluminum deuteride serves to introduce deuterium into organic compounds. An even more powerful reducing agent, is lithium triethylborohydride (LiEt₃BH), which rapidly reduces primary, secondary, allylic, benzylic, and neopentyl halides, but not tertiary (these give elimination) or aryl halides.¹²⁹³ Another powerful reagent, which reduces primary, secondary, tertiary, allylic, vinylic, aryl, and neopentyl halides, is a complex formed from lithium trimethoxyaluminum hydride, LiAlH(OMe)₃, and CuI.¹²⁹⁴ A milder reducing agent is NaBH₄ in a dipolar aprotic solvent, such as Me₂SO, DMF, or sulfolane,¹²⁹⁵ which at room temperature or above reduces primary, secondary, and some tertiary¹²⁹⁶ halides in good yield without affecting other functional groups that would be reduced by LiAlH₄, for example, COOH, COOR, CN.¹²⁹⁷ A mixture of NaBH₄ and InCl₃ efficiently reduces secondary bromides.¹²⁹⁸ Borohydride exchange resin is also an effective reducing agent in the presence of metal catalysts, such as Ni(OAc)₂,¹²⁹⁹ and Bu₄NBH₄, is also effective.¹³⁰⁰ Other reducing agents¹³⁰¹ include zinc (with acid or base), SnCl₂, SmI₂-THF-HMPA,¹³⁰² and Et₃SiH in the presence of AlCl₃.¹³⁰³ Diethyl phosphonate-Et₃N,¹³⁰⁴ phosphorus tris(dimethylamide) (Me₂N)₃P,¹³⁰⁵ and organotin hydrides R_nSnH_{4-n}¹³⁰⁶ (chiefly Bu₃SnH) usually used in conjunction with a radical

initiator, such as AIBN.¹³⁰⁷ Tributyltin hydride can be used in conjunction with transition-metal salts, such as InCl_3 .¹³⁰⁸ The organotin hydride $(\text{MeOCH}_2\text{-CH}_2\text{OCH}_2\text{CH}_2\text{CH}_2)_3\text{SnH}$ reduces alkyl halides and is water soluble, unlike Bu_3SnH .¹³⁰⁹ In a related area, silylated cyclohexadienes have been used with AIBN as radical-chain reducing reagents, effective for tertiary halides.¹³¹⁰ Other transition metal-based reducing agents include NiCl_2 ,¹³¹¹ $\text{Ni}(\text{OAc})_2/\text{Al}(\text{acac})_3/\text{NaH}$.¹³¹² Raney nickel in Z-propanol reduces primary iodides in the presence of a lactone moiety.¹³¹³ Aluminum amalgam efficiently reduced an iodohydrin to the alcohol.¹³¹⁴ A polymer-bound dialkyltin halide has been used in conjunction with NaBH_4 to reduce alkyl bromides.¹³¹⁵

Reduction, especially of bromides and iodides, can also be effected by catalytic hydrogenation,¹³¹⁶ and electrochemically.¹³¹⁷ Raney nickel by itself can reduce alkyl halides.¹³¹⁸ A good reducing agent for the removal of all halogen atoms in a polyhalo compound (including vinylic, allylic, geminal, and even bridgehead halogens) is lithium¹³¹⁹ or sodium¹³²⁰ and *t*-BuOH in THF. Propargylic halides can often be reduced with allylic rearrangement to give allenes.¹³²¹

The choice of a reducing agent usually depends on what other functional groups are present. Each reducing agent reduces certain groups and not others. This type of

selectivity is called *chemoselectivity*. A chemoselective reagent is one that reacts with one functional group (e.g., halide), but not another (e.g., C=O). For example, there are several reagents that reduce only the halogen of α -halo ketones, leaving the carbonyl group intact.¹³²² Among them are polymer-supported triphenylphosphine,¹³²³ decaborane with 10% Pd/C,¹³²⁴ Bi in aq. THF¹³²⁵ or In metal in water,¹³²⁶ and *i*-Bu₂AlH–SnCl₂.¹³²⁷ In a similar chemoselective reaction, the halogen in α -haloimines has been reduced with SnCl₂/MeOH without reducing the C=N bond.¹³²⁸

Both NaBH₃CN–SnCl₂.¹³²⁹ and the *n*-butyllithium ate complex of B-*n*-butyl-9-BBN¹³³⁰ (see p. 1077) reduce tertiary alkyl, benzylic, and allylic halides, but do not react with primary or secondary alkyl or aryl halides. Another highly selective reagent, in this case for primary and secondary iodo and bromo groups, is sodium cyanoborohydride, NaBH₃CN, in HMPA.¹³³¹ Most of the reducing agents mentioned reduce chlorides, bromides, and iodides, but organotin hydrides also reduce fluorides.¹³³² See p. 1787 for a discussion of selectivity in reduction reactions.

Vinyl halides can be reduced to the corresponding alkene in some cases.¹³³³ As mentioned above, electrochemical reduction of aryl and vinyl halides is well known.¹³³⁴ When vinyl dibromides, such as RCH=CBr₂, are treated with (MeO)₂P(=O)H and triethylamine, for example, the product is the vinyl bromide RCH=HBr.¹³³⁵ Indium in ethanol accomplishes the same transformation.¹³³⁶ Similar reduction occurs when vinyl diiodides are treated with Zn–Cu in acetic acid.¹³³⁷

With LiAlH_4 and most other metallic hydrides, the mechanism usually consists of simple nucleophilic substitution with attack by hydride ion that may or may not be completely free. The mechanism is $\text{S}_{\text{N}}2$ rather than $\text{S}_{\text{N}}1$, since primary halides react better than secondary or tertiary (tertiary generally give alkenes or do not react at all) and since Walden inversion has been demonstrated. However, rearrangements found in the reduction of bicyclic tosylates with LiAlH_4 indicate that the $\text{S}_{\text{N}}1$ mechanism can take place.¹³³⁸ There is evidence that LiAlH_4 and other metal hydrides can also reduce halides by an SET mechanism,¹³³⁹ especially those, such as vinylic,¹³⁴⁰ cyclopropyl,¹³⁴¹ or bridgehead halides, that are resistant to nucleophilic substitution. Reduction of halides by NaBH_4 in 80% aqueous diglyme¹³⁴² and by BH_3 in nitromethane¹³⁴³ takes place by an $\text{S}_{\text{N}}1$ mechanism. It is known that NaBH_4 in sulfolane reduces tertiary halides possessing a β -hydrogen by an elimination-addition mechanism.¹³⁴⁴

The mechanism for reduction of alkyl halides is not always nucleophilic substitution. For example, reductions with organotin hydrides generally¹³⁴⁵ take place by free-radical mechanisms,¹³⁴⁶ as do those with $\text{Fe}(\text{CO})_5$. Alkyl halides, including fluorides and polyhalides, can be reduced with magnesium and a secondary or tertiary alcohol (most often 2-propanol).¹³⁴⁷ This is actually an example of the occurrence in one step of the sequence:

More often the process is carried out in two separate steps (**12-36** and **12-22**).

19-54 Reduction of Alcohols¹³⁴⁸

Hydro-de-hydroxylation or Dehydroxylation

The hydroxyl groups of most alcohols can seldom be cleaved by catalytic hydrogenation and alcohols are often used as solvents for hydrogenation of other compounds. However, benzyl-type alcohols undergo the reaction readily and have often been reduced.¹³⁴⁹ Diaryl and triarylcarbinols are similarly easy to reduce and this has been accomplished with $\text{LiAlH}_4\text{—AlCl}_3$,¹³⁵⁰ with NaBH_4 in F_3CCOOH ,¹³⁵¹ and with iodine, water, and red phosphorus (OS I, 224). Other reagents have been used,¹³⁵² among them $\text{PPh}_3/\text{diethyl-azo-dicarboxylate}$ and arylsulfonyl hydrazine,¹³⁵³ PPh_3 and electrolysis,¹³⁵⁴ $\text{Me}_3\text{SiCl—MeI—MeCN}$,¹³⁵⁵ $\text{Me}_3\text{SiCl—NaI}$,¹³⁵⁶ $\text{Et}_3\text{SiH—BF}_3$,¹³⁵⁷ $\text{SmI}_2\text{—THF—HMPA}$,¹³⁵⁸ and tin and HCl. The reduction of secondary alcohols was accomplished using Ph_2SiClH and InCl_3 .¹³⁵⁹ 1,3-Diols are especially susceptible to hydrogenolysis. Tertiary alcohols can be reduced by catalytic hydrogenolysis when the catalyst is Raney nickel.¹³⁶⁰ Allylic alcohols (and ethers and acetates) can be reduced (often with accompanying allylic rearrangement) with Zn amalgam and HCl, as well as with certain other reagents.¹³⁶¹ α -Acetylenic alcohols are converted to alkynes by reduction of their cobalt carbonyl complexes with NaBH_4 and CF_3COOH .¹³⁶² Reagents that reduce the OH group

of α -hydroxy ketones without affecting the C=O group include lithium diphenylphosphide, Ph_2PLi ,¹³⁶³ red phosphorus–iodine,¹³⁶⁴ and Me_3SiI .¹³⁶⁵

Alcohols can also be reduced indirectly by conversion to a sulfonate and reduction of that compound (**19-57**). The two reactions can be carried out without isolation of the sulfonate if the alcohol is treated with pyridine– SO_3 in THF, and LiAlH_4 then added.¹³⁶⁶ Another indirect reduction that can be done in one step involves treatment of the alcohol (primary, secondary, or benzylic) with NaI, Zn, and Me_3SiCl .¹³⁶⁷ In this case, the alcohol is first converted to the iodide, which is reduced. For other indirect reductions of OH, see **19-59**.

The mechanisms of most alcohol reductions are obscure.¹³⁶⁸ Hydrogenolysis of benzyl alcohols can give inversion or retention of configuration, depending on the catalyst.¹³⁶⁹ The mechanism of electroreduction of allylic alcohols in acidic aqueous media has been examined.¹³⁷⁰

Note that tertiary benzylic alcohols are cleaved to give the aromatic compound $[\text{ArC}(\text{OH})\text{Ar}'_2 \rightarrow \text{Ar-H}]$ by heating with cesium carbonate and $\text{Pd}(\text{OAc})_2$.¹³⁷¹
OS I, 224; IV, 25, 218, 482; V, 339; VI, 769.

19-55 Reduction of Phenolic and Other Hydroxyaryl Compounds

Hydro-de-hydroxylation or Dehydroxylation, etc.

Oxygenated compounds, such as phenols, phenolic esters, and ethers, can be reduced.¹³⁷² Phenols can be reduced by distillation over zinc dust or with HI and red phosphorus, but these methods are quite poor and are seldom feasible. Catalytic hydrogenation has also been used, but the corresponding cyclohexanol (see **15-13**) is a side product.¹³⁷³

Much better results have been obtained by conversion of phenols to certain esters or ethers and reduction of the latter:

OS VI, 150. See also, OS VII, 476.

19-56 Replacement of Alkoxy by Hydrogen

Hydro-de-alkoxylation or Dealkoxylation

Simple ethers are not normally cleaved by reducing agents, although such cleavage has sometimes been reported¹³⁷⁷ (e.g., THF treated with $\text{LiAlH}_4\text{-AlCl}_3$ ¹³⁷⁸ or with a mixture of $\text{LiAlH}(\text{O}-t\text{-Bu})_3$ and Et_3B ¹³⁷⁹ gave 1-butanol; the latter reagent also cleaves methyl alkyl ethers).¹³⁸⁰ Certain types of ethers can be cleaved quite well by reducing agents.¹³⁸¹ Among these are allyl aryl,¹³⁸² vinyl aryl,¹³⁸³ benzylic ethers,^{1349,1384} and anisole¹³⁸⁵ (for epoxides, see **19-35**). 7-Oxobicyclo[2.2.1]heptanes

can be reductively cleaved with DIBAL and nickel catalysts.¹³⁸⁶ α -Methoxy ketones are demethoxylated ($\text{O}=\text{C}-\text{COMe} \rightarrow \text{O}=\text{C}-\text{CH}$) with SmI_2 .¹³⁸⁷

Acetals and ketals are resistant to LiAlH_4 and similar hydrides, and carbonyl groups are often converted to acetals or ketals for protection (**16-5**). However, a combination of LiAlH_4 and AlCl_3 ¹³⁸⁸ does reduce acetals and ketals, removing one group, as shown above.¹³⁸⁹ The actual reducing agents in this case are primarily chloroaluminum hydride (AlH_2Cl) and dichloroaluminum hydride (AlHCl_2), which are formed from the reagents.¹³⁹⁰ This conversion can also be accomplished with DIBALH,¹³⁹¹ as well as with other reagents.¹³⁹² Ortho esters are easily reduced to acetals by LiAlH_4 alone, offering a route to aldehydes, which are easily prepared by hydrolysis of the acetals (**10-6**). Mixed ketals [$\text{R}(\text{OMe})\text{OR}'$] can be demethoxylated (to give RHOR') with $\text{Bn}_3\text{SnCl}/\text{NaCHBH}_3$ in the presence of AIBN.¹³⁹³

When the reagent is LiAlH_4 , alkyl tosylates are reduced more rapidly than iodides or bromides if the solvent is Et_2O , but the order is reversed in diglyme.¹³⁹⁹ The reactivity difference is great enough so that a tosylate function can be reduced in the presence of a halide and vice versa. Tertiary allylcyclopropyl tosylates have been reduced with BuZnCl and a palladium catalyst.¹⁴⁰⁰

OS VI, 376, 762; VIII, 126. See also, OS VII, 66.

19-58 Hydrogenolysis of esters (Barton–McCombie Reaction)

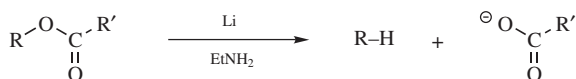

Hydro-de-thioacetoxylation

Alcohols can readily be converted to carbonate and thiocarbonate derivatives. Under radical conditions,¹⁴⁰¹ using *azobis-isobutyronitrile* (AIBN, p. 935) and Bu_3SnH , the carbonate or thiocarbonate unit is reduced and replaced with hydrogen. The overall process is reduction of the ROH unit to RH. This is called the *Barton–McCombie reaction*.¹⁴⁰² When R is cyclododecane (OCSOR), for example, this reduction yields the parent cyclododecane in 76% yield.¹⁴⁰³ When R = cyclododecane (OCSSMe), treatment with $\text{Bu}_3\text{P}=\text{O}$ and AIBN, gives the alkane in 94% yield.¹⁴⁰⁴ Both $\text{PhSiH}_3/\text{AIBN}$ ¹⁴⁰⁵ and $\text{PhSiH}_2-\text{BEt}_3\cdot\text{O}_2$ can be used.¹⁴⁰⁶ This reaction can be catalytic in Bu_3SnH .¹⁴⁰⁷ Variations include reduction of ROCSNPh derivatives using $\text{Ph}_3\text{SiH}/\text{BEt}_3$.¹⁴⁰⁸

19-59 Reductive Cleavage of Carboxylic Esters

Hydro-de-acyloxylation or Deacyloxylation

The alkyl group R of certain carboxylic esters can be reduced to RH^{1409} by treatment with lithium in ethylamine.¹⁴¹⁰ The reaction is successful when R is a tertiary or a sterically hindered secondary alkyl group. A free-radical mechanism is likely.¹⁴¹¹ Similar reduction, also by a free-radical mechanism, has been reported with sodium in HMPA-*t*-BuOH.¹⁴¹² In the latter case, tertiary R groups give high yields of RH, but primary and secondary R are converted to a mixture of RH and ROH. Both of these methods provide an indirect method of accomplishing **19-54** for tertiary R.¹⁴¹³ The same thing can be done for primary and secondary R by treating alkyl chloroformates, ROCOCl , with tri-*n*-propylsilane in the presence of *tert*-butylperoxide¹⁴¹⁴ and by treating thiono ethers ROC(=S)W (where W can be OAr or other groups) with $\text{Ph}_2\text{SiH}_2^{1415}$ or $\text{Ph}_3\text{SiH}^{1416}$ and a free-radical initiator. Allylic acetates can be reduced with NaBH_4 and a palladium complex,¹⁴¹⁷ and with $\text{SmI}_2\text{Pd(0)}$.¹⁴¹⁸ The last reagent converts propargylic acetates to allenes $\text{R}^1\text{C}=\text{C}=\text{CR}^2\text{R}^3\text{OAc} \rightarrow \text{R}^1\text{CH}=\text{C}=\text{CR}^2\text{R}^3$.¹⁴¹⁸ For other carboxylic ester reductions, see **19-62**, **19-38**, and **19-65**.

Note that acid chlorides can be reduced ($\text{R-COCl} \rightarrow \text{R-H}$) using $(\text{Me}_3\text{Si})_3\text{SiH/AIBN}$.¹⁴¹⁹

OS VII, 139.

19-60 Reduction of Hydroperoxides and Peroxides

Hydroperoxides can be reduced to alcohols with LiAlH_4 or $\text{Ph}_3\text{P}^{1420}$ or by catalytic hydrogenation. This functional group is very susceptible to catalytic

hydrogenation, as shown by the fact that a double bond may be present in the same molecule without being reduced.¹⁴²¹

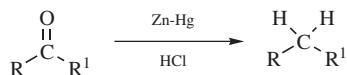

The reaction is an important step in a method for the oxidative decyanation of nitriles containing an α hydrogen.¹⁴²² The nitrile is first converted to the α -hydroperoxy nitrile by treatment with base at -78°C followed by O_2 . The hydroperoxy nitrile is then reduced to the cyanohydrin, which is cleaved (the reverse of **16-52**) to the corresponding ketone. The method is not successful for the preparation of aldehydes ($\text{R}' = \text{H}$).

Peroxides are cleaved to 2 equivalents of alcohols by LiAlH_4 , Mg/MeOH ,¹⁴²³ or by catalytic hydrogenation. Peroxides can be reduced to ethers with $\text{P}(\text{OEt})_3$.¹⁴²⁴ In a similar reaction, disulfides (RSSR') can be converted to sulfides RSR' by treatment with tris(diethylamino)phosphine, $(\text{Et}_2\text{N})_3\text{P}$.¹⁴²⁵

19-61 Reduction of Carbonyl to Methylene in Aldehydes and Ketones

Dihydro-de-oxo-bisubstitution

There are various ways of reducing the $\text{C}=\text{O}$ group of aldehydes and ketones to CH_2 .¹⁴²⁶ The two oldest, but still very popular, methods are the *Clemmensen reduction*¹⁴²⁷ and the *Wolff-Kishner reduction*. The Clemmensen reduction consists of heating the aldehyde or ketone with zinc amalgam and aq. HCl .¹⁴²⁸ Ketones are reduced more often than aldehydes. In the Wolff-Kishner reduction,¹⁴²⁹ the aldehyde or ketone is heated with hydrazine hydrate and a base (usually NaOH

or KOH). The *Huang–Minlon modification*¹⁴³⁰ of the Wolff–Kishner reaction, in which the reaction is carried out in refluxing diethylene glycol, has completely replaced the original procedure. A microwave-assisted Huang–Minlon procedure has been reported.¹⁴³¹ The reaction can also be carried out under more moderate conditions (room temperature) in DMSO with potassium *tert*-butoxide as base.¹⁴³² A new modification of the reduction treats a ketone with hydrazine in toluene with microwave irradiation, and subsequent reaction with KOH with microwave irradiation completes the Wolff–Kishner reduction.¹⁴³³ The Wolff–Kishner reaction can also be applied to the semicarbazones of aldehydes or ketones. The Clemmensen reduction is usually easier to perform, but it fails for acid-sensitive and high-molecular-weight substrates. For these cases, the Wolff–Kishner reduction is quite useful. For high-molecular-weight substrates, a modified Clemmensen reduction, using activated zinc and gaseous HCl in an organic solvent, such as ether or acetic anhydride, has proved successful.¹⁴³⁴ The Clemmensen and Wolff–Kishner reactions are complementary, since the former uses acidic and the latter basic conditions.

Both methods are fairly specific for aldehydes and ketones and can be carried out with many other functional groups present. However, certain types of aldehydes and ketones do not give normal reduction products. Under Clemmensen conditions,¹⁴³⁵ α -hydroxy ketones give either ketones (hydrogenolysis of the OH, **19-54**) or alkenes, and 1,3-diones usually undergo rearrangement (e.g., $\text{MeCOCH}_2\text{-COMe} \rightarrow \text{MeCOCHMe}_2$).¹⁴³⁶ Neither method is suitable for α,β -unsaturated ketones. These give pyrazolines¹⁴³⁷ under Wolff–Kishner conditions, while under Clemmensen conditions both groups of these molecules may be reduced or if only one group is reduced, it is the C=C bond.¹⁴³⁸ Sterically hindered ketones are resistant to both the Clemmensen and Huang–Minlon procedures, but can be reduced by vigorous treatment with anhydrous hydrazine.¹⁴³⁹ In the Clemmensen reduction, pinacols (**19-76**) are often side products.

Other reagents have also been used to reduce the C=O of aldehydes and ketones to CH_2 .¹⁴⁴⁰ Among these are Me_3SiCl followed by $\text{Et}_3\text{SiH/TiCl}_4$,¹⁴⁴¹ Ni(OAc)_2 on borohydride exchange resin,¹⁴⁴² Et_3SiH on pyridinium poly(hydrogen fluoride),

An indirect method of accomplishing the reaction is reduction of tosylhydrazones ($R_2C=N-NHTs$) to R_2CH_2 with $NaBH_4$, BH_3 , catecholborane, bis(benzyloxy)borane, or $NaBH_3CN$. The reduction of α,β -unsaturated tosylhydrazones with $NaBH_3CN$, with $NaBH_4-HOAc$, or with catecholborane proceeds with migration of the double bond to the position formerly occupied by the carbonyl carbon, even if this removes the double bond from conjugation with an aromatic ring,¹⁴⁶² for example,

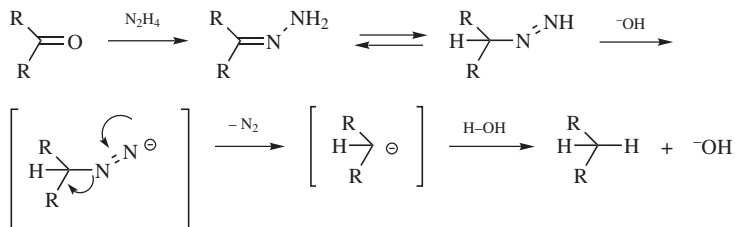

A cyclic mechanism is apparently involved:

Another indirect method is conversion of the aldehyde or ketone to a dithioacetal or ketal, and desulfurization of using Raney nickel or another reagent (14-27).

It is interesting to see that amines can be deaminated to give the corresponding methylene compounds with low-valent titanium ($TiCl_3/Li/THF$).¹⁴⁶³

The first step in the mechanism¹⁴⁶⁴ of the Wolff-Kishner reaction consists of formation of the hydrazone (16-14). It is this species that undergoes reduction in the presence of base, most likely in the following manner:

Not much is known about the mechanism of the Clemmensen reduction. Several mechanisms have been proposed,¹⁴⁶⁵ including one going through a zinc-carbene intermediate.¹⁴⁶⁶ One thing reasonably certain is that the corresponding alcohol is not an intermediate, since alcohols prepared in other ways fail to give the reaction. Note that the alcohol is not an intermediate in the Wolff-Kishner reduction either.

19-62 Reduction of Carboxylic Esters to Ethers

Dihydro-de-oxo-bisubstitution

Carboxylic esters and lactones have been reduced to ethers, although 2 equivalents of alcohol are more commonly obtained (19-38). Reduction to ethers has been accomplished with a reagent prepared from BF_3 -etherate and either LiAlH_4 , LiBH_4 , or NaBH_4 ,¹⁴⁶⁷ with trichlorosilane and uv light,¹⁴⁶⁸ and with catalytic hydrogenation. The reaction with the BF_3 reagent apparently succeeds with secondary R' , but not with primary R' , which give 19-38. Lactones give cyclic ethers.¹⁴⁶⁹ Acyloxy groups are reduced by cleavage of the $\text{C}=\text{O}$ bond, $\text{R}(\text{Ar})\text{COO}-\text{C} \rightarrow \text{C}-\text{H}$ with an excess of Ph_2SiH_2 and di-*tert*-butyl peroxide.¹⁴⁷⁰ Esters are reduced to ethers using Et_3SiH and TiCl_4 .¹⁴⁷¹ Lactones are converted to cyclic ethers by treatment with Cp_2TiCl_2 followed by Et_3SiH on Amberlyst 15.¹⁴⁷²

Thiono esters RCSOR' can be reduced to ethers $\text{RCH}_2\text{OR}'$ with Raney nickel (14-27).¹⁴⁷³ Reaction of thio esters, such as $\text{C}-\text{OC}(=\text{O})\text{Ph}$ with Ph_2SiH_2 and Ph_3SnH with BEt_3 , followed by AIBN (p. 935) leads to reduction of the $\text{C}=\text{S}$ unit to give an ether.¹⁴⁷⁴ Since the thiono esters can be prepared from carboxylic

esters (**16-11**), this provides an indirect method for the conversion of carboxylic esters to ethers. Thiol esters (RCOSR') have been reduced to thioethers (RCH₂SR').¹⁴⁷⁵

See also, **19-65, 19-59.**

19-63 Reduction of Cyclic Anhydrides to Lactones and Acid Derivatives to Alcohols

Dihydro-de-oxo-bisubstitution

Cyclic anhydrides can give lactones if reduced with Zn–HOAc, with hydrogen and platinum or RuCl₂(Ph₃P)₃,¹⁴⁷⁶ with NaBH₄,¹⁴⁷⁷ or even with LiAlH₄, although with the last-mentioned reagent diols are the more usual product. With a BINOL–AlHOEt complex, however, reduction to the lactone proceeds smoothly.¹⁴⁷⁸ With some reagents the reaction can be accomplished regioselectively, that is, only a specific one of the two C=O groups of an unsymmetrical anhydride is reduced.¹⁴⁷⁹ Open-chain anhydrides either are not reduced at all (e.g., with NaBH₄) or give 2 equivalents of alcohol. The LiAlH₄ usually reduces open-chain anhydrides to give 2 equivalents of alcohol. With cyclic anhydrides the reaction with LiAlH₄ can be controlled to give either diols or lactones.¹⁴⁸⁰ The NaBH₄ in THF, with dropwise addition of methanol, reduces open-chain anhydrides to 1 equivalent of primary alcohol and 1 equivalent of carboxylic acid.¹⁴⁸¹

Acyl halides are reduced¹⁴⁸² to alcohols by LiAlH₄ or NaBH₄, as well as by other metal hydrides (Table 19.5), but not by borane.

In general, reduction of amides to alcohols is difficult. More commonly the amide is reduced to an amine. An exception uses LiH₂NBH₃ to give the alcohol.¹⁴⁸³ Reduction with sodium metal in propanol also gives the alcohol.¹⁴⁸⁴ Acyl

19-64 Reduction of Amides to Amines

Dihydro-deoxo-bisubstitution

Amides can be reduced¹⁴⁸⁶ to amines with LiAlH_4 or by catalytic hydrogenation, but high temperatures and pressures are usually required for the latter. Even with LiAlH_4 , the reaction is more difficult than the reduction of most other functional groups, and other groups often can be reduced without disturbing an amide function. Although NaBH_4 by itself does not reduce amides, it does so in the presence of certain other reagents¹⁴⁸⁷ including iodine.¹⁴⁸⁸ Lithium borohydride reduces acetamides.¹⁴⁸⁹ Substituted amides can be reduced with these powerful reagents; secondary amides to secondary amine and tertiary amides to tertiary amines. Borane¹⁴⁹⁰ and sodium in 1-propanol¹⁴⁹¹ are good reducing agents for all three types of amides. Another reagent that reduces disubstituted amides to amines is trichlorosilane.¹⁴⁹² Other silanes, such as Et_3SiH in the presence of a rhenium catalyst, reduce amides to amines.¹⁴⁹³ Sodium (dimethylamino)borohydride reduces unsubstituted and disubstituted, but not monosubstituted amides.¹⁴⁹⁴ Electrolytic reduction of carbamates to give an amine are possible.¹⁴⁹⁵

With some RCONR, LiAlH_4 causes cleavage, and the aldehyde (**10-41**) or alcohol is obtained. Lithium triethylborohydride produces the alcohol with most *N,N*-disubstituted amides, but not with unsubstituted or *N*-substituted amides.¹⁴⁹⁶ Lactams are reduced to cyclic amines in high yields with LiAlH_4 , although cleavage sometimes occurs here too. A mixture of $\text{LiBHET}_3/\text{Et}_3\text{SiH}$ is also effective.¹⁴⁹⁷ Lactams are also reduced to cyclic amines with 9-BBN¹⁴⁹⁸ (p. 1077) or $\text{LiBH}_3\text{NMe}_2$.¹⁴⁹⁹ Imides are generally reduced on both sides,¹⁵⁰⁰ although it is sometimes possible to stop with just one. Both cyclic and acyclic imides have been reduced in this manner, although with acyclic imides cleavage is often obtained, for example,¹⁵⁰¹

Acyl sulfonamides have been reduced ($\text{RCONHSO}_2\text{Ph} \rightarrow \text{RCH}_2\text{NHSO}_2\text{Ph}$) with $\text{BH}_3\text{—SMe}_2$ ¹⁵⁰² and with SmI_2/DMPU .¹⁵⁰³

19-65 Reduction of Carboxylic Acids and Esters to Alkanes

Trihydro-de-alkoxy,oxo-tersubstitution, and so on.

The reagent titanocene dichloride reduces carboxylic esters in a different manner from that of **19-59**, **19-62**, or **19-38**. The products are the alkane RCH_3 and the alcohol $\text{R}'\text{OH}$.⁹⁰⁹ The mechanism probably involves an alkene intermediate. Aromatic acids can be reduced to methylbenzenes by a procedure involving refluxing first with trichlorosilane in MeCN, then with tripropylamine added, and finally with KOH and MeOH (after removal of the MeCN).¹⁵⁰⁴ The following sequence has been suggested:¹⁵⁰⁴

Esters of aromatic acids are not reduced by this procedure, so an aromatic COOH group can be reduced in the presence of a COOR' group.¹⁵⁰⁵ However, it is also

possible to reduce aromatic ester groups, by a variation of the trichlorosilane procedure.¹⁵⁰⁶ Both *o*- and *p*-hydroxybenzoic acids and their esters have been reduced to cresols $\text{HOC}_6\text{H}_4\text{CH}_3$ with sodium bis(2-methoxyethoxy)aluminum hydride, $\text{NaAlH}_2(\text{OC}_2\text{H}_4\text{OMe})_2$ (Red-Al).¹⁵⁰⁷ Heating a 2-pyridylbenzyl ester with ammonium formate and a ruthenium catalyst leads to reduction of the CH_2COO unit to the alkane.¹⁵⁰⁸

Carboxylic acids can also be converted to alkanes, indirectly,¹⁵⁰⁹ by reduction of the corresponding tosylhydrazides RCONHNH_2 with LiAlH_4 or borane.¹⁵¹⁰

OS VI, 747.

19-66 Hydrogenolysis of Nitriles

Hydro-de-cyanation

This transformation is not common, but given the proliferation of nitriles in organic chemistry, it is potentially quite useful. In the presence of mercuric compounds, tertiary nitriles can be reduced to the hydrocarbon with sodium cyanoborohydride.¹⁵¹¹ *gem*-Dinitriles can be reduced to the corresponding mononitrile with SmI_2 .¹⁵¹²

19-67 Reduction of the C—N Bond

Hydro-de-amination or Deamination

Benzylic amines are particularly susceptible to hydrogenolysis by catalytic hydrogenation¹⁵¹³ or dissolving metal reduction.¹⁵¹⁴ Note that the Wolff–Kishner reduction in **19-61** involved formation of a hydrazone and deprotonation by base led to loss of nitrogen and reduction. Ceric ammonium nitrate in aqueous acetonitrile has also been shown to reductively cleave the *N*-benzyl group.¹⁵¹⁵ Primary amines have been reduced to RH with hydroxylamine-*O*-sulfonic acid and

aq. NaOH to give the hydrocarbon, nitrogen gas, and the sulfate anion.¹⁵¹⁶ It is postulated that R–N=N–H is an intermediate that decomposes to the carbocation. The reaction has also been accomplished with difluoroamine HNF₂;¹⁵¹⁷ the same intermediates are postulated in this case. Treatment of aniline with 20 equivalents of NO gave benzene.¹⁵¹⁸ An indirect means of achieving the same result is the conversion of the primary amine to the sulfonamide, RNHSO₂R' (**16-102**), and treatment of this with NH₂OSO₂OH¹⁵¹⁹ or NaOH, and then NH₂Cl.¹⁵²⁰ Tosylaziridines derived from terminal alkenes are reduced to the corresponding primary tosylamine with polymethylhydrosiloxane/Pd–C.¹⁵²¹

Other indirect methods involve reduction of *N,N*-ditosylates (p. 497) with NaBH₄ in HMPA¹⁵²² and modifications of the Katritzky pyrylium–pyridinium method.¹⁵²³ Allylic and benzylic amines¹³⁴⁹ can be reduced by catalytic hydrogenolysis. Aziridines can be reductively opened with SmI₂¹⁵²⁴ or with Bu₃SnH and AIBN.¹⁵²⁵ The C–N bond of enamines is reductively cleaved to give an alkene with alane (AlH₃).¹⁵²⁶

and with 9-BBN (p. 1077) or borane methyl sulfide (BMS).¹⁵²⁷ Since enamines can be prepared from ketones (**16-13**), this is a way of converting ketones to alkenes. In the latter case, BMS gives retention of configuration [an (*E*) isomer gives the (*E*) product], while 9-BBN gives the other isomer.¹⁵²⁷ Diazo ketones are reduced to methyl ketones by HI: RCOCHN₂ + HI → RCOCH₃.¹⁵²⁸

Quaternary ammonium salts can be cleaved with LiAlH₄, R₄N⁺ + LiAlH₄ → R₃N + R⁻, as can quaternary phosphonium salts R₄P⁺. Other reducing agents have also been used, for example, lithium triethylborohydride (which preferentially cleaves methyl groups)¹⁵²⁹ and sodium in liquid ammonia. When quaternary salts

are reduced with sodium amalgam in water, the reaction is known as the *Emde reduction*. However, this reagent is not applicable to the cleavage of ammonium salts with four *saturated* alkyl groups. Of course, aziridines⁸⁹⁹ can be reduced in the same way as epoxides (19-35).

Nitro compounds, RNO_2 , can be reduced to RH^{1530} by sodium methylmercaptide, CH_3SNa , in an aprotic solvent¹⁵³¹ or by $\text{Bu}_3\text{SnH}^{1532}$. Both reactions have free-radical mechanisms.¹⁵³³ Tertiary nitro compounds can be reduced to RH by NaHTe^{1534} . Hydrogenolysis with a Pt catalyst in the gas phase has been reported to reduce nitro compounds, as well as primary and secondary amines.¹⁵³⁵ The nitro group of aromatic nitro compounds has been removed with sodium borohydride.¹⁵³⁶ This reaction involves an addition–elimination mechanism. Reduction of the C–N bond on aromatic amines with Li metal in THF generates the aryl compounds.¹⁵³⁷ Sodium nitrite, sodium bisulfite in EtOH/water/acetic acid does a similar reduction.¹⁵³⁸ Conversion of the aniline derivative to the methanesulfonamide and subsequent treatment with NaH and NH_2Cl gives the same result.¹⁵³⁹ The Bu_3SnH reagent also reduces isocyanides, RNC (prepared from RNH_2 by formylation followed by 17-31), to RH^{1540} a reaction that can also be accomplished with Li or Na in liquid NH_3^{1541} or with K and a crown ether in toluene.¹⁵⁴² α -Nitro ketones can be reduced to ketones with $\text{Na}_2\text{S}_2\text{O}_4$ – Et_3SiH in HMPA – $\text{H}_2\text{O}^{1543}$.

19-68 Reduction of Amine Oxides and Azoxy Compounds

N-Oxygen-detachment

Amine oxides¹⁵⁴⁴ and azoxy compounds (both alkyl and aryl)¹⁵⁴⁵ can be reduced practically quantitatively with triphenylphosphine.¹⁵⁴⁶ Other reducing agents, for example, LiAlH₄, NaBH₄/LiCl,¹⁵⁴⁷ H₂-Ni, PCl₃, TiCl₃,¹⁵⁴⁸ Ga/H₂O,¹⁵⁴⁹ In/TiCl₄,¹⁵⁵⁰ LiAlH₄/TiCl₄, or SbCl₂ have also been used. Indium metal with aqueous ammonium chloride in methanol gives good yields of pyridine from pyridine *N*-oxide.¹⁵⁵¹ Similar results are obtained using ammonium formate and Raney nickel¹⁵⁵² or zinc.¹⁵⁵³ Indium (III) chloride has been used for the reduction of quinoline *N*-oxide to quinoline.¹⁵⁵⁴ Polymethylhydrosiloxane with Pd-C is also an effective reducing agent for amino oxides.¹⁵⁵⁵ Nitrile oxides¹⁵⁵⁶ (R-C≡N⁺-O⁻) can be reduced to nitriles with trialkylphosphines,¹⁵⁵⁷ and isocyanates (RNCO) to isocyanides (RNC) with Cl₃SiH-Et₃N.¹⁵⁵⁸

Analogous to amino *N*-oxides, phosphine oxides (R₃P=O) are reduced to phosphines (R₃P). Treatment of a phosphine oxide with MeOTf followed by reduced

19-69 Replacement of the Diazonium Group by Hydrogen

Dediazoniatioⁿ or Hydro-de-diazoniatioⁿ

Reduction of the diazonium group (*dediazoniatioⁿ*) provides an indirect method for the removal of an amino group from an aromatic ring.¹⁵⁶¹ The best and most common way of accomplishing this is by use of hypophosphorous acid H_3PO_2 , although many other reducing agents¹⁵⁶² have been used, among them ethanol, HMPA,¹⁵⁶³ thiophenol,¹⁵⁶⁴ and sodium stannite. Ethanol was the earliest reagent used, and it frequently gives good yields, but often ethers (ArOEt) are side products. When H_3PO_2 is used, 5–15 equivalents of this reagent are required per equivalent of substrate. Diazonium salts can be reduced in nonaqueous media by several methods, including treatment with Bu_3SnH or Et_3SiH in ethers or MeCN ¹⁵⁶⁵ and by isolation as the BF_4^- salt and reduction of this with NaBH_4 in DMF.¹⁵⁶⁶ Aromatic amines can be deaminated ($\text{ArNH}_2 \longrightarrow \text{ArH}$) in one laboratory step by treatment with an alkyl nitrite in DMF¹⁵⁶⁷ or boiling THF.¹⁵⁶⁸ The corresponding diazonium salt is an intermediate.

Not many investigations of the mechanism have been carried out. It is generally assumed that the reaction of diazonium salts with ethanol to produce ethers takes place by an ionic ($\text{S}_{\text{N}}1$) mechanism while the reduction to ArH proceeds by a free-radical process.¹⁵⁶⁹ The reduction with H_3PO_2 is also believed to have a free-radical mechanism.¹⁵⁷⁰ In the reduction with NaBH_4 , an aryldiazene intermediate

(ArN=NH) has been demonstrated,¹⁵⁷¹ arising from nucleophilic attack by BH_4^- on the β nitrogen. Such diazenes can be obtained as moderately stable (half-life of several hours) species in solution.¹⁵⁷² It is not entirely clear how the aryldiazene decomposes, but there are indications that either the aryl radical $\text{AR}\cdot$ or the corresponding anion Ar^- may be involved.¹⁵⁷³

An important use of the dediazonation reaction is to remove an amino group after it has been used to direct one or more other groups to ortho and para positions. For example, the compound 1,3,5-tribromobenzene cannot be prepared by direct bromination of benzene because the bromo group is ortho-para-directing; however, this compound is easily prepared by the following sequence:

Many other compounds that would otherwise be difficult to prepare are easily synthesized with the aid of the dediazonation reaction.

Unwanted dediazonation can be suppressed by using hexasulfonated calix[6]arenes (see p. 122).¹⁵⁷⁴

Raney nickel already contains enough hydrogen for the reaction. Other sulfur compounds can be similarly desulfurized, including disulfides, thiono esters,¹⁵⁷⁷ thioamides, sulfoxides, and thioacetals.¹⁵⁷⁸ Reduction of thioacetals is an indirect way of accomplishing reduction of a carbonyl to a methylene group (see **19-61**), and it can also give the alkene if a hydrogen is present.¹⁵⁷⁹ In most of the examples given, R can also be aryl. Other reagents¹⁵⁸⁰ have also been used.¹⁵⁸¹

Lithium aluminum hydride reduces most sulfur compounds with cleavage of the C—S bond, including thiols.¹⁵⁸² Thioesters can be reduced with Ni₂B (from NiBr₂/NaBH₄).¹⁵⁸³ β-Ketosulfones are reduced with TiCl₄—Zn,¹⁵⁸⁴ TiCl₄—Sm,¹⁵⁸⁵ or Bu₃SnCl—NaCNBH₃/AIBN.¹⁵⁸⁶

An important special case of RSR reduction is desulfurization of thiophene derivatives. This proceeds with concomitant reduction of the double bonds. Many compounds have been made by alkylation of thiophene to **49**, followed by reduction to give **50**.

Thiophenes can also be desulfurized to alkenes (RCH₂CH=CHCH₂R' from **49**) with a nickel boride catalyst prepared from nickel(II) chloride and NaBH₄ in methanol.¹⁵⁸⁷ It is possible to reduce just one SR group of a dithioacetal by treatment with borane–pyridine in trifluoroacetic acid or in CH₂Cl₂ in the presence of AlCl₃.¹⁵⁸⁸ Phenyl selenides RSePh can be reduced to RH with Ph₃SnH¹⁵⁸⁹ and with nickel boride.¹⁵⁹⁰ Cleavage of the C—Se bond can also be achieved with SmI₂.¹⁵⁹¹

The exact mechanism of the Raney nickel reactions are still in doubt, although they are probably of the free-radical type.¹⁵⁹² It has been shown that reduction of thiophene proceeds through butadiene and butene, not through 1-butanethiol or other sulfur compounds, that is, the sulfur is removed before the double bonds are reduced. This was demonstrated by isolation of the alkenes and the failure to isolate any potential sulfur-containing intermediates.¹⁵⁹³

Sulfonamides are reduced to the corresponding amine by heating with Me_3SiCl and NaI .¹⁵⁹⁴

OS **IV**, 638; **V**, 419; **VI**, 109, 581, 601. See also, OS **VII**, 124, 476.

19-71 Reduction of Sulfonyl Halides and Sulfonic Acids to Thiols or Disulfides

Thiols can be prepared by the reduction of sulfonyl halides¹⁵⁹⁵ with LiAlH_4 . Usually, the reaction is carried out on aromatic sulfonyl chlorides. Zinc and acetic acid, and HI , also give the reduction. Another reagent for this reduction is Me_2SiCl_2 and Zn with dimethyl acetamide.¹⁵⁹⁶ Sulfonic acids have been reduced to thiols with a mixture of triphenylphosphine and either I_2 or a diaryl disulfide.¹⁵⁹⁷ For the reduction of sulfonyl chlorides to sulfinic acids, see **16-104**.

Disulfides RSSR can also be produced.¹⁵⁹⁸ Other sulfonic acid derivatives can be converted to disulfides. Esters, such as PhSAc , are converted to disulfides PhS-SPh with Clayan and microwave irradiation.¹⁵⁹⁹ Thiobenzoate derivatives PhSBz are similarly converted to PhS-SPh with SmI_2 .¹⁶⁰⁰ In a similar manner, $\text{RS-SO}_3\text{Na}$ is converted to RS-SR when heated with samarium metal in water.¹⁶⁰¹

19-72 Reduction of Sulfoxides and Sulfones

S-Oxygen-detachment

Sulfoxides can be reduced to sulfides by many reagents,¹⁶⁰² among them Ph_3P ,¹⁶⁰³ LiAlH_4 , HI , Bu_3SnH ,¹⁶⁰⁴ $\text{MeSiCl}_3-\text{NaI}$,¹⁶⁰⁵ $\text{H}_2-\text{Pd}-\text{C}$,¹⁶⁰⁶ $\text{NaBH}_4-\text{NiCl}_2$,¹⁶⁰⁷ NaBH_4/I_2 ,¹⁶⁰⁸ catecholborane,¹⁶⁰⁹ TiI_4 ,¹⁶¹⁰ TiCl_4/In ,¹⁶¹¹ $\text{Cp}_2\text{TiCl}_2/\text{In}$,¹⁶¹² Sm /methanolic NH_4Cl with ultrasound,¹⁶¹³ $(\text{EtO})_2\text{PCI}/\text{NEt}_3$,¹⁶¹⁴ and $\text{SiO}_2/\text{SOCl}_2$. Sulfones, however, are usually stable to reducing agents, although they have been reduced to sulfides with DIBALH , $(i\text{Bu})_2\text{AlH}$.¹⁶¹⁵ A less general reagent is LiAlH_4 , which reduces some sulfones to sulfides, but not others.¹⁶¹⁶ Heating sulfoxides with 2,6-dihydropyridine gives the corresponding sulfide.¹⁶¹⁷ Both sulfoxides and sulfones can be reduced by heating with sulfur (which is oxidized to SO_2), although the reaction with sulfoxides proceeds at a lower temperature. It has been shown by using substrate labeled with ^{35}S that sulfoxides simply give up the oxygen to the sulfur, but that the reaction with sulfones is more complex, since $\sim 75\%$ of the original radioactivity of the sulfone is lost.¹⁶¹⁸ This indicates that most of the sulfur in the sulfide product comes in this case from the *reagent*. There is no direct general

method for the reduction of sulfones to sulfoxides, but an indirect method has been reported.¹⁶¹⁹ Selenoxides can be reduced to selenides with a number of reagents.¹⁶²⁰

OS IX, 446

D. Reduction With Cleavage

19-73 de-Alkylation of Amines and Amides

Certain amines can be dealkylated, usually under reductive conditions. *N*-Allyl amines, $R_2N-CH_2CH=CH_2$ are converted to the corresponding amine, R_2N-H , with Dibal/NiCl₂dppp,¹⁶²¹ and with Pd(dba)₂dppb.¹⁶²² A mixture of TiCl₃ and Li converts *N*-benzylamines to the amine ($R_2NCH_2Ph \rightarrow R_2NH$).¹⁶²³ In the case of *N,N*-dimethyl amines, RuCl₃ and H₂O₂ demethylate the amine ($ArNMe_2 \rightarrow ArNHMe$).¹⁶²⁴ Tribenzylamines are dealkylated to give the dibenzylamine with ceric ammonium nitrate in aqueous acetonitrile.¹⁶²⁵ *N*-Benzyl indoles are cleaved to indoles with O₂, DMSO/KO*t*-Bu¹⁶²⁶ or with tetrabutylammonium fluoride.¹⁶²⁷

The process is not limited to amines. Amides can also be dealkylated. *N*-Benzyl amides are debenzylated in the presence of NBS and AIBN.¹⁶²⁸

N-Alkyl sulfonamides are dealkylated with PhI(OAc)₂ and I₂ with ultrasound to give a primary sulfonamide.¹⁶²⁹ Similar results are obtained with H₅IO₆ and a chromium catalyst.¹⁶³⁰ *tert*-Butyl sulfonamides are cleaved to the primary sulfonamide with BCl₃.¹⁶³¹

19-74 Reduction of Azo, Azoxy, and Hydrazo Compounds to Amines

Azo, azoxy, and hydrazo compounds can all be reduced to amines.¹⁶³² Metals (notably zinc) and acids, and $\text{Na}_2\text{S}_2\text{O}_4$, are frequently used as reducing agents, and Bu_3SnH with a copper catalyst has been used.¹⁶³³ Borane reduces azo compounds to amines, although it does not reduce nitro compounds.¹⁶³⁴ LiAlH_4 does not reduce hydrazo compounds or azo compounds, although with the latter, hydrazo compounds are sometimes isolated. With azoxy compounds, LiAlH_4 gives only azo compounds (**19-68**). Noted that azo compounds are reduced to the hydrazine by reaction with hydrazine hydrate in ethanol.¹⁶³⁵

OS I, 49; II, 35, 39; III, 360; X, 327. Also see, OS II, 290.

19-75 Reduction of Disulfides to Thiols**S-Hydrogen-uncoupling**

Disulfides can be reduced to thiols by mild reducing agents,¹⁶³⁶ such as zinc and dilute acid, In and $\text{NH}_4\text{Cl}/\text{EtOH}$,¹⁶³⁷ or Ph_3P and H_2O .¹⁶³⁸ The reaction can also be accomplished simply by heating with alkali.¹⁶³⁹ Among other reagents used have been LiAlH_4 , $\text{NaBH}_4/\text{ZrCl}_4$,¹⁶⁴⁰ Mg/MeOH ,¹⁶⁴¹ $\text{KBH}(\text{O}-i\text{Pr})_3$,¹⁶⁴² and hydrazine or substituted hydrazines.¹⁶⁴³

E. Reductive Coupling

19-76 Bimolecular Reduction of Aldehydes and Ketones to 1,2-Diols and Imines to 1,2-Diamines

2/O-Hydrogen-coupling and 2/N-Hydrogen-coupling

1,2-Diols (pinacols) can be synthesized by reduction of aldehydes and ketones with active metals, such as sodium, magnesium, or aluminum.¹⁶⁴⁵ Aromatic ketones give better yields than aliphatic ones. The use of a Mg-MgI_2 mixture has been called the *Gomberg-Bachmann pinacol synthesis*.¹⁶⁴⁶ As with a number of other reactions involving sodium, there is a direct electron transfer here, converting the ketone or aldehyde to a ketyl, which dimerizes.

Other reagents have been used,¹⁶⁴⁷ including Sm ,¹⁶⁴⁸ Yb ,¹⁶⁴⁹ $\text{Yb-Me}_3\text{SiCl}$,¹⁶⁵⁰ InCl_3 catalyst with Mg ,¹⁶⁵¹ Al/TiCl_3 ,¹⁶⁵² VOCl_3 catalyst with Me_3SiCl ,¹⁶⁵³

activated Mn,¹⁶⁵⁴ In with ultrasound,¹⁶⁵⁵ Zn,¹⁶⁵⁶ and a reagent prepared from TiCl₄¹⁶⁵⁷ and Mg amalgam¹⁶⁵⁸ (a low-valent titanium reagent,¹⁶⁵⁹ see 19-76). A mixture of TiCl₄¹⁶⁶⁰ or TiCl₂¹⁶⁶¹ and Zn can also be used. Unsymmetrical coupling between two different aldehydes has been achieved by the use of a vanadium complex,¹⁶⁶² while TiCl₃ in aqueous solution has been used to couple two different ketones.¹⁶⁶³ Two aldehydes have also been coupled using magnesium in water.¹⁶⁶⁴ Coupling leads to a mixture of syn- and anti-diols. "Syn-selective" reagents are Cp₂TiCl₂/Mn,¹⁶⁶⁵ TiCl₄/Bu₄I,¹⁶⁶⁶ TiI₄,¹⁶⁶⁷ TiBr₂+Cu,¹⁶⁶⁸ and NbCl₃.¹⁶⁶⁹ With SmI₂,¹⁶⁷⁰ coupling in the presence of a primary alkyl iodide leads to acyl addition using an excess of HMPA, but pinacol coupling with an excess of LiBr.¹⁶⁷¹ "Anti-selective" coupling reactions are also known: Ti-salen,¹⁶⁷² Mg with a NiCl₂ catalyst,¹⁶⁷³ Sm/SmCl₃,¹⁶⁷⁴ and TiCl₄(thf)₂ with a chiral Schiff base.¹⁶⁷⁵ Aryl

aldehydes are coupled to give the bis-trimethylsilyl ether using Mn, Me₃SiCl, and Cp₂TiCl₂.¹⁶⁷⁶

A crossed-pinacol coupling was reported using Et₂Zn and with a BINOL catalyst gave good enantioselectivity.¹⁶⁷⁷ A combination of Mg and Me₃SiCl was also used to a crossed-pinacol.¹⁶⁷⁸

Intramolecular pinacol coupling reactions are known, giving cyclic 1,2-diols.¹⁶⁷⁹ Dialdehydes have been cyclized by reaction with TiCl₃ to give cyclic 1,2-diols in good yield.¹⁶⁸⁰ A radical-induced coupling of an α,ω -dialdehyde led to *cis*-1,2-cyclopentanediol when treated with Bu₃SnH and AIBN.¹⁶⁸¹ or induced photochemically.¹⁶⁸²

Chiral additives with pinacol couplings lead to formation of a diol with moderate to good enantioselectivity.¹⁶⁸³ Chiral metal complexes in conjunction with a metal leads to diol formation with good enantioselectivity.¹⁶⁸⁴

A variation of the pinacol coupling treats acyl nitriles with indium metal and ultrasound to give a 1,2-diketone.¹⁶⁸⁵ Another variation couples acetals to give 1,2-diols.¹⁶⁸⁶

The dimerization of ketones to 1,2-diols can also be accomplished photochemically; indeed, this is one of the most common photochemical reactions.¹⁶⁸⁷ The substrate, which is usually a diaryl or aryl alkyl ketone (though a few aromatic aldehydes and dialkyl ketones have been dimerized), is irradiated with UV light in the presence of a hydrogen donor, such as isopropyl alcohol, toluene, or an amine.¹⁶⁸⁸

¹⁶⁸⁸For a review of amines as hydrogen donors in this reaction, see Cohen, S.G.; Parola, A.; Parsons, Jr., G.H. *Chem. Rev.* **1973**, *73*, 141.

In the case of benzophenone, irradiated in the presence of 2-propanol, the ketone molecule initially undergoes $n \rightarrow \pi^*$ excitation, and the singlet species thus formed crosses to the T_1 state with a very high efficiency.

The T_1 species abstracts hydrogen from the alcohol (p. 347), and then dimerizes. The $i\text{PrO}\cdot$ radical, which is formed by this process, donates $\text{H}\cdot$ to another molecule of ground-state benzophenone, producing acetone and another molecule of **51**. This mechanism¹⁶⁸⁹ predicts that the quantum yield for the disappearance of benzophenone should be 2, since each quantum of light results in the conversion of 2 equivalents of benzophenone to **51**. Under favorable experimental conditions, the observed quantum yield does approach 2. Benzophenone abstracts hydrogen with very high efficiency. Other aromatic ketones are dimerized with lower quantum yields, and some (e.g., *p*-aminobenzophenone, *o*-methylacetophenone) cannot be dimerized at all in 2-propanol (although *p*-aminobenzophenone, e.g., can be dimerized in cyclohexane¹⁶⁹⁰). The reaction has also been carried out electrochemically.¹⁶⁹¹

A coupling reaction similar to pinacol coupling has been used with imines, which dimerize to give 1,2-diamines. A number of reagents have been used, including treatment with $\text{TiCl}_4\text{-Mg}$,¹⁶⁹² In/aq. EtOH ,¹⁶⁹³ Zn/aq. NaOH ,¹⁶⁹⁴ $\text{Cp}_2\text{VCl}_2/\text{Zn/}$

PhMe₂SiCl,¹⁶⁹⁵ Et₂AlCl,¹⁶⁹⁶ SmI₂,¹⁶⁹⁷ and (for silylated imines) NbCl₄(thf)₂.¹⁶⁹⁸ When electroreduction was used, it was even possible to obtain cross-products, by coupling a ketone to an *O*-methyl oxime:¹⁶⁹⁹ *O*-Methyl oxime ethers are coupled to give 1,2-diamines using Zn and TiCl₄.¹⁷⁰⁰ Aldehydes are converted to 1,2-diamines by treatment with TMS₂NH, NaH, and Li metal in 5 *M* LiClO₄ in ether, with sonication.¹⁷⁰¹ Hemiaminals are coupled to give 1,2-diamines with TiI₄/Zn.¹⁷⁰² Amides are converted to 1,2-diamines with Cp₂TiF₂ and PhMeSiH₂.¹⁷⁰³ Samarium(II) iodide was used to couple iminium salts, giving the 1,2-diamine.¹⁷⁰⁴ Ketones can be treated with Yb, and then an imine to give amino alcohols.¹⁷⁰⁵

The *N*-methoxyamino alcohol could then be reduced to the amino alcohol.¹⁶⁹⁹ A photochemical coupling has also been reported.¹⁷⁰⁶ A variation of this reaction treats an imine with Yb in THF/HMPA and then an aldehyde to give a 1,2-bis(imine).¹⁷⁰⁷ OS I, 459; II, 71; X, 312; 81, 26.

19-77 Bimolecular Reduction of Aldehydes or Ketones to Alkenes

De-oxygen-coupling

Aldehydes and ketones, both aromatic and aliphatic (including cyclic ketones), can be converted in high yields to dimeric alkenes by treatment low valent titanium,¹⁷⁰⁸ initially generated with TiCl₃ and a zinc–copper couple.¹⁷⁰⁹ This is called

Indoles have been prepared from ortho-acyl amides with Ti(powder) and Me_3SiCl ¹⁷²² or with $\text{TiCl}_3\text{-C}_8\text{K}$.¹⁷²³ Benzofurans have been prepared by a closely related reaction.¹⁷²⁴

Unsymmetrical alkenes can be prepared from a mixture of two ketones in a cross-coupling reaction, if one is in excess.¹⁷²⁵ An aldehyde and a ketone were cross-coupled using $\text{Yb}(\text{OTf})_3$, for example.¹⁷²⁶ The mechanism consists of initial coupling of two radical species to give a 1,2-dioxygen compound (a titanium pinacolate), which is then deoxygenated.¹⁷²⁷

OS VII, 1.

19-78 Acyloin Ester Condensation

52

When carboxylic esters are heated with sodium in refluxing ether or benzene, a bimolecular reduction takes place, and the product is an α -hydroxy ketone (called an acyloin).¹⁷²⁸ The reaction, called the *acyloin ester condensation*,¹⁷²⁹ is quite successful when R is alkyl. Acyloins with long chains have been prepared in this way, for example, $\text{R} = \text{C}_{17}\text{H}_{35}$, but for high-molecular-weight esters, toluene or xylene is used as the solvent. Modifications to this procedure have been reported, including an ultrasound-promoted acyloin condensation in ether,¹⁷³⁰ which improved the yields of four-, five-, and six-membered rings, and Olah's procedure, which was also done in ether.¹⁷³¹

The acyloin condensation has been used with great success, in boiling xylene, to prepare cyclic acyloins from diesters.¹⁷³² The yields are 50–60% for the preparation

of 6- and 7-membered rings, 30–40% for 8- and 19-membered, and 60–95% for rings of 10–20 members. Even larger rings have been closed in this manner. This is one of the best ways of closing rings of 10 members or more. The reaction has been used to close 4-membered rings,¹⁷³³ although this is generally not successful. The presence of double or triple bonds does not interfere.¹⁷³⁴ Even a benzene ring can be present, and many paracyclophane derivatives (**53**) with $n = 9$ or more have been synthesized in this manner.¹⁷³⁵

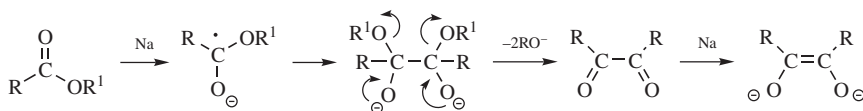

53

54

Yields in the acyloin condensation can be improved by running the reaction in the presence of chlorotrimethylsilane Me_3SiCl , in which case the dianion **52** is converted to the bis silyl enol ether **54**, which can be isolated and subsequently hydrolyzed to the acyloin with aqueous acid.¹⁷³⁶ This is now the standard way to conduct the acyloin condensation. Among other things, this method inhibits the Dieckmann condensation¹⁷³⁷ (**16-85**), which otherwise competes with the acyloin condensation when a five-, six-, or seven-membered ring can be closed (note that the ring formed by a Dieckmann condensation is always one carbon atom smaller than that formed by an acyloin condensation of the same substrate). The Me_3SiCl method is especially good for the closing of four-membered rings.¹⁷³⁸

The mechanism is not known with certainty, but it is usually presumed that the diketone RCOCOR is an intermediate,¹⁷³⁹ since small amounts of it are usually isolated as side products, and when it is resistant to reduction (e.g., *t*-Bu—COCO—*t*-Bu), it is the major product. A possible sequence (analogous to that of **19-76**) is

¹⁷³⁹Another mechanism, involving addition of the ketyl to another molecule of ester (rather than a dimerization of two ketyl radicals), in which a diketone is not an intermediate, has been proposed: Bloomfield, J.J.; Owsley, D.C.; Ainsworth, C.; Robertson, R.E. *J. Org. Chem.* **1975**, 40, 393.

A large surface area for the sodium is usually required for good results in this coupling, consistent with a surface reaction. In order to account for the ready formation of large rings, which means that the two ends of the chain must approach each other even although this is conformationally unfavorable for long chains, it may be postulated that the two ends become attached to nearby sites on the surface¹⁷⁴⁰ of the sodium. Although high dilution techniques are not always necessary, effective stirring (high speed stirrer at 2000–2500 rpm) is usually required to generate “sodium sand”. Highly pure sodium gives poorer results, and a small percentage of potassium is important. Up to 50% potassium (1:1 Na/K)¹⁷⁴¹ has been used in acyloin condensations.

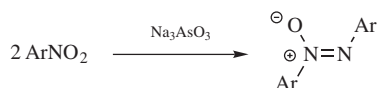

In a related reaction, aromatic carboxylic acids were condensed to α -diketones ($2\text{ArCOOH} \rightarrow \text{ArCOCOAr}$) on treatment with excess Li in dry THF in the presence of ultrasound.¹⁷⁴²

The acyloin condensation was used in an ingenious manner to prepare the first reported catenane (see p. 131).¹⁷⁴³ This synthesis of a catenane produced only a small yield and relied on chance for threading the molecules before ring closure.

OS II, 114; IV, 840; VI, 167.

19-79 Reduction of Nitro to Azoxy Compounds

Nitro-azoxy reductive transformation

Azoxy compounds can be obtained from nitro compounds with certain reducing agents, notably sodium arsenite, sodium ethoxide, NaTeH,¹⁷⁴⁴ NaBH₄–PhTe–TePh,¹⁷⁴⁵ and glucose. The most probable mechanism with most reagents is that one molecule of nitro compound is reduced to a nitroso compound and another to a hydroxylamine (**19-46**), and these combine (**12-51**). The combination step is rapid compared to the reduction process.¹⁷⁴⁶ Nitroso compounds can be reduced to azoxy compounds with triethyl phosphite or triphenylphosphine¹⁷⁴⁷ or with an alkaline aqueous solution of an alcohol.¹⁷⁴⁸

19-80 Reduction of Nitro to Azo Compounds***N-De-bisoxxygen-coupling***

Nitro compounds can be reduced to azo compounds with various reducing agents, of which LiAlH_4 and zinc and alkali are the most common. A combination of triethylammonium formate and lead in methanol is also effective.¹⁷⁴⁹ With many of these reagents, slight differences in conditions can lead either to the azo or azoxy (**19-79**) compound. By analogy to **19-79**, this reaction may be looked on as a combination of ArN=O and ArNH_2 (**13-24**). However, when the reducing agent was NaBH_4 ,¹⁷⁵⁰ it was shown that azoxy compounds were intermediates. Nitroso compounds can be reduced to azo compounds with LiAlH_4 . Dicarborane, with a catalytic amount of acetic acid, reduces aromatic nitro compounds to the amine.¹⁷⁵¹

Nitro compounds can be further reduced to hydrazo compounds with zinc and sodium hydroxide, with hydrazine hydrate and Raney nickel,¹⁷⁵² or with LiAlH_4 mixed with a metal chloride such as TiCl_4 or VCl_3 .¹⁷⁵³ The reduction has also been accomplished electrochemically.

OS III, 103.

F. Reactions in Which an Organic Substrate is Both Oxidized and Reduced

Some reactions that belong in this category have been considered in earlier chapters. Among these are the Tollens' condensation (**16-43**), the benzil-benzilic acid rearrangement (**18-6**), and the Wallach rearrangement (**18-43**).

19-81 The Cannizzaro Reaction**Cannizzaro Aldehyde Disproportionation**

Aromatic aldehydes, and aliphatic ones with no α -hydrogen, give the *Cannizzaro reaction* when treated with NaOH or other strong bases.¹⁷⁵⁴ In this reaction, one molecule of aldehyde oxidizes another to the acid and is itself reduced to the primary alcohol. Aldehydes with an α -hydrogen do not give the reaction, because when these compounds are treated with base the aldol reaction (**16-34**) is much faster.¹⁷⁵⁵ Normally, the best yield of acid or alcohol is 50% each, but this can

be altered in certain cases. Solvent-free reactions are known.¹⁷⁵⁶ On the other hand, high yields of alcohol can be obtained from almost any aldehyde by running the reaction in the presence of formaldehyde.¹⁷⁵⁷ In this case, the formaldehyde reduces the aldehyde to alcohol and is itself oxidized to formic acid. In such a case, where the oxidant aldehyde differs from the reductant aldehyde, the reaction is called the *crossed-Cannizzaro reaction*.¹⁷⁵⁸ The Tollens' condensation (16-43) includes a crossed-Cannizzaro reaction as its last step. A Cannizzaro reaction run on 1,4-dialdehydes (note that α hydrogens are present here) with a rhodium catalyst gives ring closure, for example,¹⁷⁵⁹

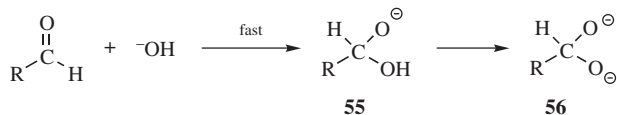

The product is the lactone derived from the hydroxy acid that would result from a normal Cannizzaro reaction. Chiral additives have been used, but with bis(oxazolidine) derivatives the reaction proceeded with poor enantioselectivity.¹⁷⁶⁰

α -Keto aldehydes give internal Cannizzaro reactions:

This product is also obtained on alkaline hydrolysis of compounds of the formula RCOCHX_2 . Similar reactions have been performed on α -keto acetals¹⁷⁶¹ and γ -keto aldehydes.

The mechanism¹⁷⁶² of the Cannizzaro reaction¹⁷⁶³ involves a hydride shift (an example of mechanism type 2, p. 1706). First OH^- adds to the $\text{C}=\text{O}$ to give **55**, which may lose a proton in the basic solution to give the diion **56**.

¹⁷⁶³See for example, Swain, C.G.; Powell, A.L.; Sheppard, W.A.; Morgan, C.R. *J. Am. Chem. Soc.* **1979**, 101, 3576; Watt, C.I.F. *Adv. Phys. Org. Chem.* **1988**, 24, 57, 81–86.

The strong electron-donating character of O^- greatly facilitates the ability of the aldehydic hydrogen to leave with its electron pair. Of course, this effect is even stronger in **56**. Hydride is transferred to another molecule of aldehyde. The hydride can come from **55** or **56**:

If the hydride ion comes from **55**, the final step is a rapid proton transfer. In the other case, the acid salt is formed directly, and the alkoxide ion acquires a proton from the solvent. Evidence for this mechanism is (1) The reaction can be first order in base and second order in substrate (thus going through **55**) or, at higher base concentrations, second order in each (going through **56**); and (2) when the reaction was run in D_2O , the recovered alcohol contained no α deuterium,¹⁷⁶⁴ indicating that the hydrogen comes from another equivalent of aldehyde and not from the medium.¹⁷⁶⁵

OS I, 276; II, 590; III, 538; IV, 110.

19-82 The Tishchenko Reaction

Tishchenko aldehyde-ester disproportionation

When aldehydes, with or without a hydrogen, are treated with aluminum ethoxide, one molecule is oxidized and another reduced, as in **19-81**, but here they are found as the ester. The process is called the *Tishchenko reaction*. Crossed-Tishchenko reactions are also possible. With more strongly basic alkoxides, such as magnesium or sodium alkoxides, aldehydes with an α hydrogen give the aldol reaction. Treatment of a dialdehyde, such as phthalic dicarboxaldehyde (phthalaldehyde) with CaO , leads to a lactone.¹⁷⁶⁶ Like **19-81**, this reaction has a mechanism that

¹⁷⁶⁴Fredenhagen, H.; Bonhoeffer, K.F. *Z. Phys. Chem. Abt. A* **1938**, *181*, 379; Hauser, C.R.; Hamrick, Jr., P.J.; Stewart, A.T. *J. Org. Chem.* **1956**, *21*, 260.

¹⁷⁶⁵When the reaction was run at 100°C , in $\text{MeOH}-\text{H}_2\text{O}$, isotopic exchange was observed (the product from PhCDO had lost some of its deuterium): Swain, C.G.; Powell, A.L.; Lynch, T.J.; Alpha, S.R.; Dunlap, R.P. *J. Am. Chem. Soc.* **1979**, *101*, 3584. Side reactions were postulated to account for the loss of deuterium. See, however, Chung, S. *J. Chem. Soc. Chem. Commun.* **1982**, 480.

¹⁷⁶⁶Seki, T.; Hattori, H. *Chem. Commun.* **2001**, 2510.

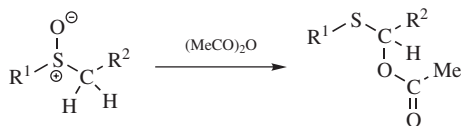

involves hydride transfer.¹⁷⁶⁷ The Tishchenko reaction can also be catalyzed¹⁷⁶⁸ by ruthenium complexes,¹⁷⁶⁹ by Cp_2ZrH_2 ¹⁷⁷⁰ or $\text{BuTi}(\text{O}i\text{Pr})_4\text{Li}$,¹⁷⁷¹ and, for aromatic aldehydes, by disodium tetracarbonylferrate, $\text{Na}_2\text{Fe}(\text{CO})_4$.¹⁷⁷² Both CaO (noted above) and SrO have been used as catalysts.¹⁷⁷³ A bisphenylenedioxy bis-(aluminum) catalyst has been used to convert aliphatic aldehydes to the corresponding ester.¹⁷⁷⁴ The bis $\text{Al}(\text{O}i\text{Pr})_2$ derivative of catechol has also been used as a catalyst.¹⁷⁷⁵

A Tishchenko–aldol-transfer reaction was reported using β -hydroxy ketones and an aldehydes with an AlMe_3 catalyst, giving a mono acyl diol.¹⁷⁷⁶

OS I, 104.

19-83 The Pummerer Rearrangement¹⁷⁷⁷

Pummerer methyl sulfoxide rearrangement

When sulfoxides bearing an α -hydrogen are treated with acetic anhydride, the product is an α -acetoxy sulfide. This is one example of the *Pummerer rearrangement*, in which the sulfur is reduced while an adjacent carbon is oxidized.¹⁷⁷⁸ The product is readily hydrolyzed (**10-6**) to the aldehyde R_2CHO .¹⁷⁷⁹ Besides acetic anhydride, other anhydrides and acyl halides give similar products. Inorganic acids, such as HCl, also give the reaction, and $\text{RSOCH}_2\text{R}'$ can be converted to $\text{RSCHCIR}'$ in this way. Sulfoxides can also be converted to α -halo sulfides¹⁷⁸⁰ by other

reagents, including sulfonyl chloride, NBS, and NCS. Enantioselective Pummerer rearrangements are known.¹⁷⁸¹ Uncatalyzed thermal rearrangements are also known.¹⁷⁸²

The following four-step mechanism has been proposed for the reaction between acetic anhydride and DMSO:¹⁷⁸³

For DMSO and acetic anhydride, step 4 is intermolecular, as shown by ¹⁸O isotopic labeling studies.¹⁷⁸⁴ With other substrates, however, step 4 can be inter- or intramolecular, depending on the structure of the sulfoxide.¹⁷⁸⁵ Depending on the substrate and reagent, any of the first three steps can be rate determining. In the case of Me₂SO treated with (F₃CCO)₂O, the intermediate corresponding to **57**¹⁷⁸⁶ could be isolated at low temperature, and on warming gave the expected product.¹⁷⁸⁷ There is much other evidence for this mechanism.¹⁷⁸⁸

A sila-Pummerer rearrangement has been reported.¹⁷⁸⁹

¹⁷⁸⁹Kirpichenko, S.V.; Suslova, E.N.; Albanov, A.I.; Shainyan, B.A. *Tetrahedron Lett.* **1999**, *40*, 185.

In the *Willgerodt reaction*, a straight- or branched-chain aryl alkyl ketone is converted to the amide and/or the ammonium salt of the acid by heating with ammonium polysulfide.¹⁷⁹⁰ The carbonyl group of the product is always at the end of the chain. Thus $\text{ArCOCH}_2\text{CH}_3$ gives the amide and the salt of $\text{ArCH}_2\text{CH}_2\text{COOH}$, and $\text{ArCOCH}_2\text{CH}_2\text{CH}_3$ gives derivatives of $\text{ArCH}_2\text{CH}_2\text{CH}_2\text{COOH}$. However, yields sharply decrease with increasing length of chain. The reaction has also been carried out on vinylic and ethynyl aromatic compounds and on aliphatic ketones, but yields are usually lower in these cases. Unlike the Pummerer rearrangement (19-83), which involves transposition of an oxygen from S to C, the Willgerodt reaction involves oxygen migration *and* oxidation of the organic species. The use of sulfur and a dry primary or secondary amine (or ammonia), as the reagent is called the *Kindler modification* of the Willgerodt reaction.¹⁷⁹¹ The product in this case is $\text{Ar}(\text{CH}_2)_n\text{CSNR}_2$,¹⁷⁹² which can be hydrolyzed to the acid. Particularly good results are obtained with morpholine as the amine. For volatile amines, the HCl salts can be used instead, with NaOAc in DMF at 100°C.¹⁷⁹³ Dimethylamine has also been used in the form of dimethylammonium dimethylcarbamate, $\text{Me}_2\text{NCOO}^- \text{Me}_2\text{NH}_2^+$.¹⁷⁹⁴ The Kindler modification has also been applied to aliphatic ketones.¹⁷⁹⁵ Thioamides have been prepared from ketones in a base-catalyzed reaction.¹⁷⁹⁶

Alkyl aryl ketones can be converted to arylacetic acid derivatives in an entirely different manner. The reaction consists of treatment of the substrate with silver nitrate and I_2 or Br_2 ,¹⁷⁹⁷ or with thallium nitrate, MeOH, and trimethyl orthoformate adsorbed on Montmorillonite K10, an acidic clay.¹⁷⁹⁸

The mechanism of the Willgerodt reaction is not completely known, but some conceivable mechanisms can be excluded. Thus, one might suppose that the alkyl group becomes completely detached from the ring, and then attacks it with its other

end. However, this possibility is ruled out by experiments such as the following: When isobutyl phenyl ketone (**58**) is subjected to the Willgerodt reaction, the product is **59**, not **60**, which would arise if the end carbon of the ketone became bonded to the ring in the product:¹⁷⁹⁹

This also excludes a cyclic-intermediate mechanism similar to that of the Claisen rearrangement (**18-33**). Another important fact is that the reaction is successful for singly branched side chains, such as **58**, but not for doubly branched side chains, as in PhCOCHMe_3 .¹⁷⁹⁹ Still another piece of evidence is that compounds oxygenated along the chain give the same products; thus $\text{PhCOCH}_2\text{CH}_3$, PhCH_2COMe , and $\text{PhCH}_2\text{CH}_2\text{CHO}$ all give $\text{PhCH}_2\text{CH}_2\text{CONH}_2$.¹⁸⁰⁰ All these facts point to a mechanism consisting of consecutive oxidations and reductions along the chain, although just what form these take is not certain. Initial reduction to the hydrocarbon can be ruled out, since alkylbenzenes do not give the reaction. In certain cases, imines¹⁸⁰¹ or enamines¹⁸⁰² have been isolated from primary and secondary amines, respectively, and these have been shown to give the normal products, leading to the suggestion that they may be reaction intermediates.

The Literature of Organic Chemistry

All discoveries in the laboratory must be published somewhere if the information is to be made generally available. A new experimental result that is not published might as well not have been obtained, insofar as it benefits the entire chemical world. The total body of chemical knowledge (called *the literature*) is located on the combined shelves of all the chemical libraries in the world. Anyone who wishes to learn whether the answer to any chemical question is known, and, if so, what the answer is, has only to turn to the contents of these shelves. Indeed, the very expressions “is known,” “has been done,” and so on, really mean “has been published.” To the uninitiated, the contents of the shelves may appear formidably large, but fortunately the process of extracting information from the literature of organic chemistry is usually not difficult. In this appendix, we will examine the literature of organic chemistry.¹ It is quite clear that The Literature can be divided into two broad categories: primary sources and secondary sources. A *primary source* publishes the original results of laboratory investigations. Books, indexes, and other publications that cover material that has previously been published in primary sources are called *secondary sources*. It is because of the excellence of the secondary sources in organic chemistry (especially *Chemical Abstracts*[™], SciFinder[®], and Beilstein) that literature searching is comparatively not difficult. The two chief kinds of primary source are journals and patents. There are several types of secondary source.

¹For books on the chemical literature, see Wolman, Y. *Chemical Information*, 2nd ed., Wiley, NY, 1988; Maizell, R.E. *How to Find Chemical Information*, 2nd ed., Wiley, NY, 1987; Mellon, M.G. *Chemical Publications*, 5th ed., McGraw-Hill, NY, 1982; Skolnik, H. *The Literature Matrix of Chemistry*, Wiley, NY, 1982; Antony, A. *Guide to Basic Information Sources in Chemistry*, Jeffrey Norton Publishers, NY, 1979; Bottle, R.T. *Use of the Chemical Literature*, Butterworth, London, 1979; Woodburn, H.M. *Using the Chemical Literature*, Marcel Dekker, NY, 1974. For a three-part article on the literature of organic chemistry, see Hancock, J.E.H. *J. Chem. Educ.* 1968, 45, 193–199, 260–266, 336–339.

PRIMARY SOURCES

Journals

For well over 100 years, nearly all new work in organic chemistry (except for that disclosed in patents) has been published in journals. There are thousands of journals that publish chemical papers, in many countries and in many languages. Some print papers covering all fields of science; some are restricted to chemistry; some to organic chemistry; and some are still more specialized. Fortunately for the sanity of organic chemists, the vast majority of important papers in “pure” organic chemistry (as opposed to “applied”) are published in relatively few journals, perhaps 50 or fewer. The concept of “pure” organic chemistry is not as useful because organic chemistry is now important in many areas. Literature that is important to an organic chemist is found in journals and patents that focus on bioorganic, organometallic, materials science, separation science, medicinal chemistry, pharmaceutical sciences, and medicine to name a few. The reader is therefore cautioned that the journals listed in this section have organic chemistry as their primary focus, but are by no means the only sources of information concerning organic chemistry. The literature is vast and many journals are published weekly, and some semi-monthly.

In addition to ordinary papers, there are two other types of publications in which original work is reported: *notes* and *communications*. A note is a brief paper, often without a summary (nearly all papers are published with summaries or abstracts prepared by the author). Otherwise, a note is similar to a paper.² Communications (also called *letters*) are also brief and usually without summaries (though some journals now publish summaries along with their communications, a welcome trend). However, communications differ from notes and papers in three respects:

1. They are brief, not because the work is of small scope, but because they are condensed. Usually, they include only the most important experimental details or none at all.
2. They are often of immediate significance. Journals that publish communications make every effort to have them appear as soon as possible after they are received. Some papers and notes are of great importance, and some are of lesser importance, but all communications are supposed to be of high importance. With modern computer technology, communications can often be published in a matter of weeks, and the on-line version (e.g., the American Chemical Society ASAP papers) can be found before the print version appears.
3. Communications are preliminary reports, and the material in them may be republished as papers at a later date, in contrast to the material in papers and notes, which cannot be republished.

²In some journals, notes are called “short communications,” an unfortunate practice, because they are not communications as that term is defined in the text.

Although papers (we use the term in its general sense, to cover notes and communications also) are published in many languages, the English-speaking chemist is in a fairly fortunate position. At present well over half of the important papers in organic chemistry are published in English. Not only are American, British, and British Commonwealth journals published almost entirely in English, but so are many others around the world. There are predominantly English-language journals published in Japan, Italy, Czechoslovakia, Sweden, The Netherlands, Israel, and other countries. In a reorganization, six prominent European journals (*Chemische Berichte*, *Liebigs Annalen der Chemie*, *Bulletin de la Société Chimique de France*, *Bulletin des Sociétés Chimique Belges*, *Recueil des Travaux Chimiques des Pays-Bas*, and *Gazzetta Chimica Italiana*) have been discontinued. In their place is the *European Journal of Organic Chemistry*, published in English. Most of the articles published in other languages have summaries printed in English also. For many years, the second most important language (in terms of the number of organic chemical papers published) was Russian, and most of these papers are available in English translation, although in most cases, 6 months to 1 year later. With the political changes in Russia, however, many of these Journals have been modified or discontinued. Important papers have been published in German and French for >200 years, and these are generally not available in translation, so that the organic chemist should have at least a reading knowledge of these languages. In recent years, however, fewer papers in French or German have appeared without an English translation, such as in the journal *Angewandte Chemie*, which in 1962 became available in English under the title *Angewandte Chemie International Edition in English*. Of course, a reading knowledge of French and German (especially German) is critical for the older literature. Before ~1920, more than one-half of the important chemical papers were in these languages. It must be realized that the original literature is never obsolete. With the rise of China in the scientific community, journals are published in Chinese, and there are journals published in Japanese. Work by Chinese and Japanese scientists regularly appears in English-language journals, however. Secondary sources become superseded or outdated, but nineteenth century journals are found in most chemical libraries and are still consulted. Table A.1 presents a list of the more important current journals that publish original papers³ and communications in organic chemistry. Some of them also publish review articles, book reviews, and other material. Changes in journal title have not been infrequent; footnotes to the table indicate some of the more important, but some of the other journals listed have also undergone title changes. In 1999, the *Journal of Organic Chemistry* stopped publishing communications, and these are now published in a new journal, *Organic Letters*.

The primary literature has grown so much in recent years that attempts have been made to reduce the volume. One such attempt is the *Journal of Chemical Research*, begun in 1977. The main section of this journal, called the "Synopsis," publishes synopses, which are essentially long abstracts, with references. The full texts of most of the papers are published only in microfiche and miniprint versions.

³In Table A.1, notes are counted as papers.

TABLE A.1. A List of the More Important *Current Journals That Currently Publish Original Papers in Organic Chemistry*^a

No.	Name	Papers or Communications	Issues per Year
1	Angewandte Chemie (1887) ⁴	C ⁵	12
2	Angewandte Chemie International Edition (1962) ⁶	C ⁷	48
3	Australian Journal of Chemistry (1948)	P	12
4	Bioorganic Chemistry (1971)	P ⁵	4
5	Bioorganic & Medicinal Chemistry Letters (1991)	C	12
6	Bulletin of the Chemical Society of Japan (1926)	P	12
7	Canadian Journal of Chemistry (1929)	P,C	12
8	Carbohydrate Research (1965)	P,C	22
9	Chemistry, a European Journal (1995)	P	24
10	Chemistry, an Asian Journal (2006)	New	New
11	Chemistry and Industry (London) (1923)	C	24
12	Chemistry Letters (1972)	C	12
13	Chimia (1947)	C ⁵	12
14	Collection of Czechoslovak Chemical Communications (1929)	P	12
15	Doklady Chemistry (1922) ⁴	C	12
17	European Journal of Organic Chemistry (1998)	P	12
18	Helvetica Chimica Acta (1918)	P	8
19	Heteroatom Chemistry (1990)	P	6
20	Heterocycles (1973)	C ⁵	12
21	Indian Journal of Chemistry (Section B)	P	12
22	International Journal of chemical Kinetics (1969)	P	12
23	Israel Journal of Chemistry (1963)	P ⁸	4
23	Journal of the American Chemical Society (1879)	P,C	52
25	Journal of Carbohydrate Chemistry (1981)	P,C	6
26	Journal of Chemical Research, Synopses (1977)	P	12
27	Chemical Communications (1965)	C	24
28	Journal of Combinatorial Chemistry (2000)	P,C	6
29	Journal of Computational Chemistry (1979)	P	16
30	Journal of Fluorine Chemistry (1971)	P,C	12

⁴These journals are available in English translation.⁵These journals also publish review articles regularly.⁶These journals are available in English translation.⁷These journals also publish review articles regularly.⁸Each issue of this journal is devoted to a specific topic.

TABLE A.1 (Continued)

No.	Name	Papers or Communications	Issues per Year
31	Journal of Heterocyclic Chemistry (1964)	P,C	12
32	Journal of the Indian Chemical Society (1924)	P	12
33	Journal of Lipid Research (1959)	P	12
34	Journal of Medicinal Chemistry (1958)	P,C	12
35	Journal of Molecular Structure (1967)	P,C	16
36	Journal of Organometallic Chemistry (1963)	P,C	48
37	Journal of Organic Chemistry (1936)	P,C	26
38	Journal of Photochemistry and Photobiology, A: Chemistry (1972)	P	12
39	Journal of Physical Organic Chemistry (1988)	P	12
40	Journal of Polymer Science Part A (1962)	P	24
41	Journal für Praktische Chemie (1834)	P	6
42	Macromolecules (1968)	P,C	26
43	Liebigs Annalen der Chemie (1832)	P	12
44	Mendeleev Communications (1991)	C	8
45	Monatshefte für Chemie (1870)	P	12
46	New Journal of Chemistry (1977) ⁹	P	11
47	Organometallics (1982)	P,C	12
48	Organic and Biomolecular Chemistry (2003)	P	24
49	Organic Letters (1999)	C	12

51	Organic Preparations and Procedures International (1969)	P ⁵	6
52	Organic Process Research & Development (1997)	P	6
53	Photochemistry and Photobiology (1962)	P ⁵	12
54	Polish Journal of Chemistry (1921) ⁹	PC	12
55	Pure and Applied Chemistry (1960)	¹⁰	12
56	Research on Chemical Intermediates (1973) ¹¹	P ⁵	6
57	Russian Journal of Organic Chemistry (1984)	P,C	12
58	Sulfur Letters (1982)	C	6
59	Synlett (1989)	C ⁵	12
60	Synthetic Communications (1971)	C	22
61	Synthesis (1969)	P ⁵	12
62	Tetrahedron (1958)	P ⁵	52
63	Tetrahedron: Asymmetry (1990)	PC	12
64	Tetrahedron Letters (1959)	C	52

^aThese Journals are listed in alphabetical order of *Chemical Abstracts*TM abbreviations, Which Are Indicated in Boldface. Also given are the year of founding, number of issues per year as of 1998, and whether the journal primarily publishes papers (P), communications (C), or both.

⁹Before 1978 this journal was called *Roczniki Chemii*.

¹⁰*Pure Appl. Chem.* publishes IUPAC reports and lectures given at IUPAC meetings.

¹¹Before 1989 this journal was called *Reviews of Chemical Intermediates*.

For some years, the American Chemical Society journals, including *J. Am. Chem. Soc.* and *J. Org. Chem.*, have provided supplementary material for some of their papers. This material is available on-line, and for older literature from the Microforms and Back Issues Office at the ACS Washington, DC, office, either on microfiche or as a photocopy. Many other journals now offer supplementary material, generally experimental procedures, supporting spectral data and crystallographic data. These practices have not yet succeeded in substantially reducing the total volume of the world's primary chemical literature.

Patents

In many countries, including the United States, it is possible to patent a new compound or a new method for making a known compound (either laboratory or industrial procedures), as long as the compounds are useful. It comes as a surprise to many to learn that a substantial proportion of the patents granted (perhaps 20–30%) have been chemical patents. Chemical patents are part of the chemical literature, and both U.S. and foreign patents are regularly abstracted by *Chemical Abstracts*TM. In addition to learning about the contents of patents from this source, chemists may consult the *Official Gazette* of the U.S. Patent Office, which, published weekly and available in many libraries, lists titles of all patents issued that week. Bound volumes of all U.S. patents are kept in a number of large libraries, including the New York Public Library, which also has an extensive collection of foreign patents. Photocopies of any U.S. patent and most foreign patents can be obtained at low cost from the U.S. Patent and Trademark Office, Washington, DC, 20231. Many patents can now be obtained on-line as well. In addition, *Chemical Abstracts*TM lists, in the introduction to the first issue of each volume, instructions for obtaining patents from 26 countries. Patents are also available via SciFinder[®].

Although patents are often very useful to the laboratory chemist, and no literature search is complete that neglects relevant patents, as a rule they are not as reliable as papers. There are two reasons for this:

1. It is in the interest of the inventor to claim as much as possible. Therefore, they may, for example, actually have carried out a reaction with ethanol and with 1-propanol, but will claim all primary alcohols, and perhaps even secondary and tertiary alcohols, glycols, and phenols. An investigator repeating the reaction on an alcohol that the inventor did not use may find that the reaction gives no yield at all. In general, it is safest to duplicate the actual examples given, of which most chemical patents contain one or more.
2. Although legally a patent gives an inventor a monopoly, any alleged infringements must be protected in court, and this may cost a good deal of money. Therefore some patents are written so that certain essential details are concealed or entirely omitted. This practice is not exactly cricket, because a patent is supposed to be a full disclosure, but patent attorneys are generally

skilled in the art of writing patents, and procedures given are not always sufficient to duplicate the results.

Fortunately, the above statements do not apply to all chemical patents: many make full disclosures and claim only what was actually done. It must also be pointed out that it is not always possible to duplicate the work reported in every paper in a journal due to the use of proprietary catalysts, equipment, or procedures. Note, however, that some work is not published or patented, but rather maintained within the company as a trade secret. Such work is not, of course, available to the public.

SECONDARY SOURCES

Journal articles and patents contain virtually all of the original work in organic chemistry. However, if there were no indexes, abstracts, review articles, and other secondary sources, the literature would be unusable, because it is so vast that no one could hope to find anything in particular. Fortunately, the secondary sources are excellent. There are various kinds and the categories tend to merge. Our classification is somewhat arbitrary.

Listings of Titles

The profusion of original papers is so great that publications that merely list the titles of current papers find much use. Such lists are primarily methods of alerting the chemist to useful papers published in journals that they do not normally read. This approach, using print versions containing lists or journals and articles, is not used much nowadays. Most journals are available on-line, and many have the original papers, with supplemental material, as HTML and pdf¹² documents. The pdf document can be downloaded to the searcher's desktop, usually for a fee, and is most convenient. *Chemical Abstracts*TM was originally available on-line as *CAS ONLINE*. *CAS ONLINE* was discontinued when *STN*[®] (a service that *CAS* operates in cooperation with the German organization *FIZ Karlsruhe*, see below) was introduced in 1984. All of the *Chemical Abstracts*TM literature can be accessed using *CAS* databases online. Many libraries and companies pay the appropriate fees, so accessing the journals is usually quite easy via those organizations. Search engines allow one to quickly scan an enormous amount of literature from office or home. In addition, most browsers have on-line searching capabilities via various search engines, and simply typing in an author, a topic, a chemical, or a few key words can lead to important articles or information. Some of the important on-line technology will be discussed below. However, some of the available resources¹³ include Specialty Citation Indexes, Science Citation Index ExpandedTM, Web of Science[®],

¹²Adobe Acrobat[®] files.

¹³See <http://scientific.thomson.com/products/categories/citation/>

Science Citation Index[®], ISI ProceedingsSM, Reaction Citation Index[™], and the Derwent Innovations IndexSM. Science Citation Index[®] is available on STN[®], where it is called SciSearch. We will begin with the older print-versions for chemical searches.

A print-version “title” publication covering the whole of chemistry is *Current Contents Physical, Chemical & Earth Sciences*,¹⁴ which began in 1967 and appears weekly, contains the contents pages of all issues of ~800 journals in chemistry, physics, earth sciences, mathematics, and allied sciences. Each issue contains an index of important words taken from the titles of the papers listed in that issue, and an author index, which, however, lists only the first-named author of each paper. The author’s address is also given, so that one may write for reprints. An on-line service is available called Current Contents Connect[®] is a multidisciplinary Web resource providing access to complete bibliographic information from >8000 of the world’s leading scholarly journals and >2000 books.¹⁵

CAS databases on-line described below allows one to search a variety of databases, including journal titles.

Abstracts

Listings of titles are valuable, as far as they go, but they do not tell what is in the paper, beyond the implications carried by the titles. Most current journals contain a graphic abstract as well as a title and a brief print description of the research. The graphical abstract is extremely useful for scanning the literature presented in a journal, and both the print and graphical abstracts are available on-line for most journals.

From the earliest days of organic chemistry, abstracts of papers have been widely available, often as sections of journals whose principal interests lay elsewhere.¹⁶ At the present time there are only two publications entirely devoted to abstracts covering the whole field of chemistry. One of these, *Referativnyi Zhurnal, Khimiya*, which began in 1953, is published in Russian and is chiefly of interest to Russian-speaking chemists. The other is *Chemical Abstracts*[™] (CA). This publication, which appears weekly, prints abstracts in English of virtually every paper containing original work in pure or applied chemistry published anywhere in the world.¹⁷ More than 9500 currently published journals are covered, in many languages. In addition, CA publishes abstracts of every patent of chemical interest from 50 national and international patent offices. *Chemical Abstracts*[™] lists and indexes, but does not abstract review articles and books. The abstracts currently appear in 80 sections, of which sections 21–34 are devoted to organic chemistry, under such

¹⁴Title pages of organic chemistry journals are also carried by *Current Contents Life Sciences*, which is a similar publication covering biochemistry and medicine.

¹⁵<http://scientific.thomson.com/products/ccc/>

¹⁶For example, *Chem. Ind. (London)* publishes abstracts of papers that appear in other journals. In the past, journals, such as *J. Am. Chem. Soc.*, *J. Chem. Soc.*, and *Berchti* also did so.

¹⁷For a guide to the use of CA, see Schulz, H. *From CA to CAS ONLINE*; VCH: NY, 1988.

headings as Alicyclic Compounds, Alkaloids, Physical Organic Chemistry, Heterocyclic Compounds (One Heteroatom), and so on. Each abstract of a paper begins with a heading that gives (1) the abstract number;¹⁸ (2) the title of the paper; (3) the authors' names as fully as given in the paper; (4) the authors' address; (5) the abbreviated name of the journal (see Table A.1);¹⁹ (6) the year, volume, issue, and page numbers; and (7) the language of the paper. In earlier years, *CA* gave the language only if it differed from the language of the journal title. Abstracts of patents begin with the abstract number, title, inventor and company (if any), patent number, patent class number, date patent issued, country of priority, patent application number, date patent applied for, and number of pages in the patent. The body of the abstract is a concise summary of the information in the paper. For many common journals the author's summary (if there is one) is used in *CA* as it appears in the original paper, with perhaps some editing and additional information. Each issue of *CA* contains an author index, a patent index, and an index of keywords taken from the titles and the texts or contexts of the abstracts. The patent index lists all patents in order of number. The same compound or method is often patented in several countries. *Chemical Abstracts* will abstract only the first patent, but it does list the patent numbers of the duplicated patents in the patent index along with all previous patent numbers that correspond to it. Before 1981, there were separate Patent Number Indexes and Patent Concordances (the latter began in 1963).

At the end of each section of *CA*, there is a list of cross-references to related papers in other sections.

*Chemical Abstracts*TM is, of course, highly used for "current awareness"; it allows one to read, in one place, abstracts of virtually all new work in chemistry, though its large size puts a limit on the extent of this type of usefulness.²⁰ *Chemical Abstracts*TM is even more useful as a repository of chemical information, a place for finding out what was done in the past. This value stems from the excellent indexes, which enable the chemist in most cases to ascertain quickly where information is located. From the time of its founding in 1907 until 1961, *CA* published annual indexes. Since 1962 there are two volumes published each year, and a separate index is issued for each volume. For each volume there is an index of subjects, authors, formulas, and patent numbers. Beginning in 1972, the subject index has been issued in two parts, a chemical substance index and a general subject index, which includes all entries that are not the names of single chemical substances. However, the indexes to each volume become essentially superseded as collective indexes are issued. The first collective indexes are 10-year (decennial) indexes, but the volume of information has made 5-year indexes necessary since 1956. Collective indexes published to date are shown in Table A.2. Thus a user of the indexes at the time of this writing would consult the collective indexes through 1995 and the semiannual indexes thereafter. The 14th collective index (covering

¹⁸Beginning in 1967. See p. 1880.

¹⁹These abbreviations are changed from time to time. Therefore the reader may notice inconsistencies.

²⁰It is possible to subscribe to *CA Selects*, which provides copies of all abstracts within various narrow fields, such as organofluorine chemistry, organic reaction mechanisms, and organic stereochemistry.

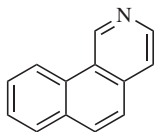

TABLE A.2. CA Collective Indexes Published

Collective Index	Subject and General Subject	Chemical Substance	Author	Formula	Patent
1	1907–1916		1907–1916		
2	1917–1926		1917–1926		1907–1936
3	1927–1936		1927–1936	1920–1946	
4	1937–1946		1937–1946		1937–1946

14	1997–2001	1997–2001	1997–2001	1997–2001	1997–2001
15	2002–2006	2002–2006	2002–2006	2002–2006	2002–2006

1997–2001) appeared in 2002. The 15th Collective index will be issued only in CD ROM, as well as any subsequent collective, presumably.

Beginning with the eighth collective index period, *CA* has published an *Index Guide*. This publication gives structural formulas and/or alternate names for thousands of compounds, as well as many other cross-references. It is designed to help the user efficiently and rapidly to find *CA* references to subjects of interest in the general subject, formula, and chemical substance indexes. Each collective index contains its own *Index Guide*. A new *Index Guide* is issued every 18 months. The *Index Guide* is necessary because the *CA* general subject index is a “controlled index,” meaning it restricts its entries only to certain terms. For example, anyone who looks for the term “refraction” in the general subject index will not find it. The *Index Guide* includes this term, and directs the reader to “Electromagnetic wave, refraction of,” “Sound and ultrasound, refraction of,” and other terms, all of which will be found in the general subject index. Similarly, the chemical substance index usually lists a compound only under one name, the approved *CA* name. Trivial and other names will be found in the *Index Guide*. For example, the term “methyl carbonate” is not in the chemical substance index, but the *Index Guide* does have this term, and tells us to look for it in the chemical substance index under the headings “carbonic acid, esters, dimethyl ester” (for Me_2CO_3) and “carbonic acid, esters, monomethyl ester” (for MeHCO_3). Furthermore, the *Index Guide* gives terms related to the chosen term, helping users to broaden a search. For example, one who looks for “Atomic orbital” in the *Index Guide* will find the terms “Energy Level,” “Molecular orbital,” “Atomic integral,” and “Exchange, quantum mechanical, integrals for,” all of which are controlled index terms.

Along with each index (annual, semiannual, or collective) appears an index of ring systems. This valuable index enables the user to ascertain immediately if any ring system appears in the corresponding subject or chemical substance index and under what names. For example, someone wishing to determine whether any compounds containing this ring system

Benz(*h*)isoquinoline

are reported in the 1982–1986 collective index (even if they did not know the name) would locate, under the heading “3-ring systems,” the listing **6, 6, 6** (since the compound has three rings of six members each), under which they would find the sub-listing C₅N–C₆–C₆ (since one ring contains five carbons and a nitrogen while the others are all-carbon), under which is listed the name benz(*h*)isoquinoline, as well as the names of 30 other systems C₅N–C₆–C₆. A search of the chemical substance index under these names will give all references to these ring systems that appeared in *CA* from 1982 to 1986.

Before 1967, *CA* used a two-column page, with each column separately numbered. A row of letters from *a* to *h* appeared down the center of the page. These letters are for the guidance of the user. Thus an entry 7337*b* refers to the *b* section of column 7337. In early years, superscript numbers (e.g., 4327⁵), were used in a similar manner. In very early years, these numbers were not printed on the page at all, though they are given in the decennial indexes, so that the user must mentally divide the page into nine parts. Beginning with 1967, abstracts are individually numbered and column numbers are discarded. Therefore, beginning with 1967, index entries give abstract number rather than column number. The abstract numbers are followed by a letter that serves as a check character to prevent miscopying errors in computer handling. To use the *CA* general subject, chemical substance, and formula indexes intelligently requires practice, and the student should become familiar with representative volumes of these indexes and with the introductory sections to them, as well as with the *Index Guides*.

In the *CA* formula indexes, formulas are listed in order of (1) number of carbon atoms; (2) number of hydrogen atoms; (3) other elements in alphabetic order. Thus, all C₃ compounds are listed before any C₄ compound; all C₅H₇ compounds before any C₅H₈ compound; C₇H₁₁Br before C₇H₁₁N; C₉H₆N₄S before C₉H₆O, and so on. Deuterium and tritium are represented by D and T and treated alphabetically, for example, C₂H₅DO after C₂H₅Cl and before C₂H₅F or C₂H₆.

Since 1965, *CA* has assigned a Registry Number to each unique chemical substance; CAS Registry Number[®]. This is a number of the form [766-51-8] that remains invariant, no matter what names are used in the literature. More than

10 million numbers have already been assigned and thousands are added each week. At one time, all numbers published with the *CA* preferred names appeared in a multivolume “Registry Handbook,” but this work was discontinued. The CAS Registry contains >27 million organic and inorganic substances and >57 million sequences.²¹ For a discussion of online searching see pp. 1901–1905.

There were a number of earlier abstracting publications now defunct. The most important are *Chemisches Zentralblatt* and *British Abstracts*. These publications are still valuable because they began before *CA* and can therefore supply abstracts for papers that appeared before 1907. Furthermore, even for papers published after 1907, *Zentralblatt* and *British Abstracts* are often more detailed. *Zentralblatt* was published, under various names, from 1830 to 1969.²² *British Abstracts* was a separate publication from 1926 to 1953, but earlier abstracts from this source are available in the *Journal of the Chemical Society* from 1871 to 1925.

Beilstein

This publication is so important to organic chemistry that it deserves a section by itself. Beilstein’s *Handbuch der Organischen Chemie*, usually referred to as *Beilstein*, lists all the known organic compounds reported in the literature during its period of coverage. We will first describe the print version, particularly important for older literature. This discussion will be followed by a description of the on-line version of Beilstein – Crossfire Beilstein. For each compound are given: all names; the molecular formula; the structural formula; all methods of preparation (briefly, e.g., “by refluxing 1-butanol with NaBr and sulfuric acid”); physical constants, such as melting point and refractive index; other physical properties; chemical properties including reactions; occurrence in nature (i.e., which species it was isolated from); biological properties, if any; derivatives with melting points; analytical data, and any other information that has been reported in the literature.²³ Equally important, for every piece of information, a reference is given to the original literature. Furthermore, the data in *Beilstein* have been critically evaluated. That is, all information is carefully researched and documented, and duplicate and erroneous results are eliminated. Some compounds are discussed in two or three lines and others require several pages. The value of such a work should be obvious.

The first three editions of *Beilstein* are obsolete. The fourth edition (*vierte Auflage*) covers the literature from its beginnings through 1909. This edition, called *das Hauptwerk*, consists of 27 volumes. The compounds are arranged in order of a

²¹This total is updated daily. See <http://www.cas.org/cgi-bin/regreport.pl>.

²²An “obituary” of *Zentralblatt* by Weiske, which gives its history and statistical data about its abstracts and indexes, was published in the April 1973 issue of *Chem. Ber.* (pp. I–XVI).

²³For a discussion of how data are processed for inclusion in *Beilstein*, see Luckenbach, R.; Ecker, R.; Sunkel, J. *Angew. Chem. Int. Ed.* **1981**, *20*, 841.

system too elaborate to discuss fully here.²⁴ The compounds are divided into three divisions that are further subdivided into “systems”:

Division	Volumes	System Numbers
I. Acyclic Compounds	1–4	1–499
II. Carbocyclic Compounds	5–16	450–2359
III. Heterocyclic Compounds	17–27	2360–4720

Das Hauptwerk is still the basis of *Beilstein* and has not been superseded. The later literature is covered by supplements that have been arranged to parallel *das Hauptwerk*. The same system is used, so that the compounds are treated in the same order. The first supplement (*erstes Ergänzungswerk*) covers 1910–1919; the second supplement (*zweites Ergänzungswerk*) covers 1920–1929; the third supplement (*drittes Ergänzungswerk*) covers 1930–1949; the fourth supplement (*viertes Ergänzungswerk*) covers 1950–1959, and the fifth supplement covers 1960–1979. Like *das Hauptwerk*, each supplement contains 27 volumes,²⁵ except that supplements 3 and 4 are combined for Vols. 17–27, so that for these volumes the combined third and fourth supplement covers the years 1930–1959. Each supplement has been divided into volumes in the same way as *das Hauptwerk*, and, for example, compounds found in Vol. 3, system number 199 of *das Hauptwerk* will also be found in Vol. 3, system number 199 of each supplement. To make cross-referencing even easier, each supplement gives, for each compound, the page numbers at which the same compound can be found in the earlier books. Thus, on page 554 of Vol. 6 of the fourth supplement, under the listing phenetole are found the symbols (H 140; E I 80; E II 142; E III 545) indicating that earlier information on phenetole is given on page 140 of Vol. 6 of *das Hauptwerk*, on page 80 of the first, page 142 of the second, and page 545 of the third supplement. Furthermore, each page of the supplements contains, at the top center, the corresponding page numbers of *das Hauptwerk*. Since the same systematic order is followed in all six series, location of a compound in any one series gives its location in the other five. If a compound is found, for example, in Vol. 5 of *das Hauptwerk*, one has but to note the page number and scan Vol. 5 of each supplement until that number appears in the top center of the page (the same number often covers several pages). Of course, many compounds are found in only one, two, three, four, or five of the series, since no work may have been published on that compound during a

²⁴For descriptions of the *Beilstein* system and directions for using it, see Sunkel, J.; Hoffmann, E.; Luckenbach, R. *J. Chem. Educ.* **1981**, *58*, 982; Luckenbach, R. *CHEMTECH* **1979**, 612. The Beilstein Institute has also published two English-language guides to the system. One, available free, is *How to Use Beilstein*; Beilstein Institute: Frankfurt/Main, **1979**. The other is by Weissbach, O. *A Manual for the Use of Beilstein's Handbuch der Organischen Chemie*, Springer, NY, **1976**. An older work, which many students will find easier to follow, is by Huntress, E.H. *A Brief Introduction to the Use of Beilstein's Handbuch der Organischen Chemie*, 2nd ed., Wiley, NY, **1938**.

²⁵In some cases, to keep the system parallel and to avoid books that are too big or too small, volumes are issued in two or more parts, and, in other cases, two volumes are bound as one.

particular period covered. From *das Hauptwerk* to the fourth supplement, *Beilstein* is in German, though it is not difficult to read since most of the words are the names of compounds (a *Beilstein* German–English Dictionary, available free from the publisher, is in many libraries). For the fifth supplement (covering 1960–1979), which is in English, publication of Division III began before the earlier divisions. At the time of this writing, Vols. 17–22 (totaling 70 separate parts exclusive of index volumes) of this supplement have been published, as well as a combined index for Volumes 17–19. This index covers only the fifth supplement. The subject portion of this index, which lists compound names only, gives these names in English.

Volumes 28 and 29 of *Beilstein* are subject and formula indexes, respectively. The most recent complete edition of these volumes is part of the second supplement and covers only *das Hauptwerk* and the first two supplements (though complete indexes covering *das Hauptwerk* and the first four supplements have been announced to appear in the next few years). For Vol. 1, there is a cumulative subject and a cumulative formula index, which combine *das Hauptwerk* and the first four supplements.²⁶ Similar index volumes, covering all four supplements, have been issued for the other volumes, 2–27. Some of these are combined (e.g., 2–3, 12–14, and 23–25). For English-speaking chemists (and probably for many German-speaking chemists) the formula indexes are more convenient. Of course (except for the fifth supplement indexes), one must still know some German, because most formula listings contain the names of many isomers. If a compound is found only in *das Hauptwerk*, the index listing is merely the volume and page numbers (e.g., 1, 501). Roman numbers are used to indicate the supplements, for example, 26, 15, I 5, II 7. Thus the subject and formula indexes lead at once to locations in *das Hauptwerk* and the first four supplements. The *Beilstein* formula indexes are constructed the same way as the *CA* indexes (p. 1880).

There is also a fourth division of *Beilstein* (systems 4721–4877) that covers natural products of uncertain structure: rubbers, sugars, and so on. These are treated in Vols. 30 and 31, which do not go beyond 1935, and which are covered in the collective indexes. These volumes will not be updated. All such compounds are now included in the regular *Beilstein* volumes.

Like *CA*, *Beilstein* is available on-line, with the useful search engine *CrossFire Beilstein*. The *Beilstein* database is one of the best databases for organic chemistry, particularly synthetic organic chemistry. It contains information on ~9.4 million organic substances that have been fully characterized, as well as 9.8 million reactions. Information available includes:²⁷

- Structure and reaction diagrams
- Identification information (name, formula, registry numbers, etc.)

²⁶Most page number entries in the combined indexes contain a letter, for example, CHBr₂Cl 67f, II 33a, III 87d, IV, 81. These letters tell where on the page to find the compound and are useful because the names given in the index are not necessarily those used in the earlier series. The letter “a” means the compound is the first on its page, “b” is the second, and so on. No letters are given for the fourth supplement.

²⁷<http://gethelp.library.upenn.edu/guides/tutorials/scitech/beilstein/BCWhat.html>

- Isolation and purification information
- Derivatives
- Physical properties, including
- Structure and energy parameters
- State of matter and change of state information
- Transport phenomena
- Optical properties
- Spectra (UV, VIS, MS, NMR, IR, ESR, X-ray, etc.)
- Electrical and magnetic properties
- Electrochemistry
- Behavior of liquid/solid, liquid/liquid, and liquid/vapor systems
- Solution behavior
- Energy data
- Optical data
- Boundary surface phenomena
- Adsorption
- Association
- Pharmacological and ecological data

Not all compounds contain all different types of data. Some data, often those quantities that can be described by a number, word, or short phrase, are given explicitly in the record for the compound. Others simply have a literature reference. The factual data, of which there are 260 million, are only experimental data, scientifically measured.

Coverage of the Literature and Search Capabilities

Beilstein references the chemical literature published in ~175 prestigious organic chemistry journals²⁸ from 1771 to date. It is updated quarterly. The database may be searched using structures and/or text (property information, chemical name, molecular formula).” Figure A. 1 shows the on-line page after a structure has been drawn using the drawing tools provided with the program, used by Crossfire to begin a session. Figure A. 2 shows an on-line page that displays data obtained after a structure search. The variety of tools available for searching is much more extensive than the ones shown in Figs. A.1 and A.2. One can use the structure editor to draw a specific structure, and it is possible to draw two or more structures, label them as reactant and/or product and search for a chemical reactions or transformation. A variety of data can be accessed for a compound or a reaction, and the output includes the chemical structures, references to the primary literature, physical, and spectral properties where available.

²⁸See <http://www.mdl.com/products/pdfs/BSJournals.pdf>.

Tables of Information

In addition to *Beilstein*, there are many other reference works in organic chemistry that are essentially compilations of data. These books are very useful and often save the research worker a great deal of time. In this section we discuss some of the more important of such works.

1. The sixth edition of *Heilbron's Dictionary of Organic Compounds*, J. Buckingham, Ed., 9 vols., Chapman and Hall, London, **1996**, contains brief listings of >150,000 organic compounds, giving names, structural formulas, physical properties, and derivatives, with references. For many entries additional data concerning occurrence, biological activity, and toxicity hazard information are also given. The arrangement is alphabetical. The dictionary contains indexes of names, formulas, heteroatoms, and CA Registry Numbers. Annual supplements, with cumulative indexes, have appeared since 1983. A similar work, devoted to organometallic compounds, is the 2nd edition of the *Dictionary of Organometallic Compounds*, 6 vols. in its 5th supplement,

²⁹See http://www.mdl.com/products/knowledge/crossfire_commander/.

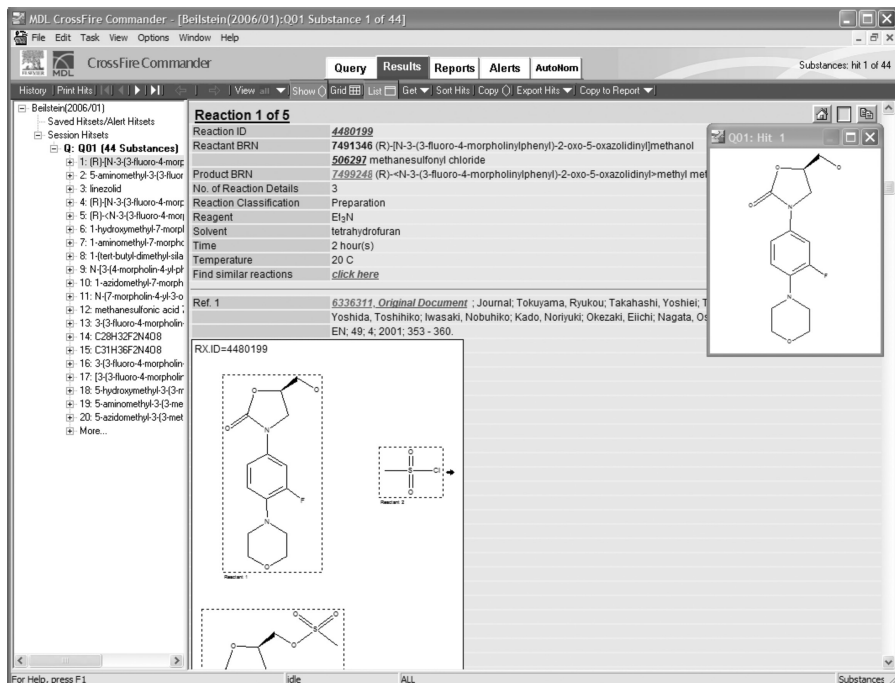

Fig. A.2. Preparation Data from CrossFire Beilstein.³⁰ Beilstein Data: Copyright (c) 1988–2006, Beilstein Institut zur Foerderung der Chemischen Wissenschaften licensed to Beilstein GmbH and MDL Information Systems GmbH. All rights reserved.

published by Chapman and Hall in **1989**. Another, *Dictionary of Steroids*, 2 vols., 1991, is also published by Chapman and Hall.

2. A multivolume compendium of physical data is Landolt-Börnstein's *Zahlenwerte und Funktionen aus Physik, Chemie, Astronomie, Geophysik, und Technik*, 6th ed., Springer, Berlin, **1950**–. There is also a “New Series,” for which the volumes are given the English title *Numerical Data and Functional Relationships in Science and Technology*, as well as the German title. This compendium, which is not yet complete, lists a great deal of data, some of which are of interest to organic chemists (e.g., indexes of refraction, heats of combustion, optical rotations, and spectral data). Literature references are given for all data.
3. *The Handbook of Chemistry and Physics*, CRC Press, Boca Raton, FL (called the “rubber handbook”), which is revised annually (87th ed., **2006–2007**), is a valuable repository of data quickly found. For organic chemists the most important table is “Physical Constants of Organic Compounds,”

³⁰See http://www.mdl.com/products/knowledge/crossfire_beilstein/index.jsp. Also see, <http://chemistry.library.wisc.edu/beilstein/quickguide6.htm>

which lists names, formulas, color, solubilities, and physical properties of thousands of compounds. However, there are many other useful tables. A similar work is *Lange's Handbook of Chemistry*, 16th ed., McGraw-Hill, New York, **2004**. Another such handbook, but restricted to data of interest to organic chemists, is *Dean's Handbook of Organic Chemistry*, 2nd ed., McGraw-Hill, New York, **2003**. This book also contains a long table of "Physical Constants of Organic Compounds," and has much other information including tables of thermodynamic properties, spectral peaks, pK_a values, bond distances, and dipole moments.

4. A list of most of the known natural compounds (e.g., terpenes, alkaloids, carbohydrates), to which structures have been assigned, along with structural formulas, melting points, optical rotations, and references, is provided in Devon and Scott, *Handbook of Naturally Occurring Compounds*, 3 vols., Academic Press, New York, **1972**.
5. Dreisbach, *Physical Properties of Chemical Compounds*, Advances in Chemistry Series Nos. 15, 22, 29, American Chemical Society, Washington, DC, **1955–1961** lists many physical properties of >1000 organic compounds.
6. Physical properties of thousands of organometallic compounds, with references, are collected in five large compendia: the *Dictionary of Organometallic Compounds*, mentioned under item 1, above; Dub, *Organometallic Compounds*, 2nd ed., 3 vols. with supplements and index, Springer, New York, **1966–1975**; Hagihara, Kumada, and Okawara, *Handbook of Organometallic Compounds*, W. A. Benjamin, New York, 1968; and Kaufman, *Handbook of Organometallic Compounds*, Van Nostrand, Princeton, NJ, 1961; *Comprehensive Organometallic Chemistry II*, 14 Vols, Pergamon, 1995.
7. The *Merck Index*, 13th ed., Merck and Company, Rahway, NJ, **2001** is a good source of information about chemicals of medicinal importance. Many drugs are given three types of name: chemical name (which is the name an organic chemist would give it; of course, there may well be more than one); generic name, which must be placed on all containers of the drug; and trade names, which are different for each company that markets the drug. For example, the generic name for 1-(4-chlorobenzhydryl)-4-methylpiperazine is chlorcyclazine. Among the trade names for this drug, which is an antihistamine, are Trihistan, Perazyl, and Alergicide. The *Merck Index* is especially valuable because it gives all known names of all three types for each compound and the names are cross-indexed. Also given, for each compound, are the structural formula, CA preferred name and Registry Number, physical properties, medicinal and other uses, toxicity indications, and references to methods of synthesis. There are indexes of formulas and Registry Numbers, and miscellaneous tables. The 10th edition of the *Merck Index* (1983) also includes a lengthy list of organic name reactions, with references. Although the 11th edition omitted this list, it was restored in the 12th and subsequent editions.

Note that the Merck Index Online™ is also available.

8. There are two publications that list properties of azeotropic mixtures. Timmermans, *The Physicochemical Constants of Binary Systems in Concentrated Solutions*, 4 vols., Interscience, New York, **1959–1960**, is by far the more comprehensive. The other is *Azeotropic Data*, 2 vols., Advances in Chemistry Series Nos. 6 and 35, American chemical Society, Washington, DC, **1952, 1962**.
9. Thousands of dipole moments, with references, are collected in McClellan, *Tables of Experimental Dipole Moments*, Vol. 1, W.H. Freeman, San Francisco, CA, **1963**; Vol. 2, Rahaara Enterprises, El Cerrita, CA, **1974**.
10. *Tables of Interatomic Distances and Configurations in Molecules and Ions*, London chemical Society Special publication No. 11, 1958, and its supplement, Special publication No. 18, **1965**, include bond distances and angles for hundreds of compounds, along with references.
11. The *Ring Systems Handbook*, published in **1988** by the Chemical Abstracts Service, provides the names and formulas of ring and cage systems that have been published in *CA*. The ring systems are listed under a system essentially the same as that used for the *CA* index of ring systems (p. \$\$\$). Each entry gives the *CA* index name and Registry Number for that ring system. In many cases, a *CA* reference is also given. There is a separate Formula Index (for the parent ring systems) and a Ring Name Index. Cumulative supplements are issued twice a year. The *Ring Systems Handbook* supersedes earlier publications called *The Parent Compound Handbook* and *The Ring Index*.
12. The Sadtler Research Laboratories publish large collections of IR, UV, NMR and other spectra, in loose-leaf form. Indexes are available.
13. Infrared, UV, NMR, Raman, and mass spectral data, as well as melting-point, boiling-point, solubility, density, and other data for >30,000 organic compounds are collected in the *CRC Handbook of Data on Organic Compounds*, 2nd ed., 9 vols., CRC Press, Boca Raton, FL, **1988**, edited by Weast and Grasselli. It differs from the Sadtler collection in that the data are given in tabular form (lists of peaks) rather than reproduction of the actual spectra, but this book has the advantage that all the spectral and physical data for a given compound appear at one place. References are given to the Sadtler and other collections of spectra. Volumes 7–9 contain indexes of spectral peaks for IR, UV, ¹H NMR, ¹³C NMR, mass, and Raman spectra, as well as indexes of other names, molecular formulas, molecular weights, and physical constants. Annual updates began appearing in **1990** (the first one is called Vol. 10).
14. The *Aldrich Library of Infrared Spectra*, 3rd ed., Aldrich chemical Company, Milwaukee, WI, **1981**, by Pouchert contains >12,000 IR spectra so arranged that the user can readily see the change that takes place in a given spectrum when a slight change is made in the structure of a molecule. The same company also publishes the *Aldrich Library of FT-IR Spectra* and the *Aldrich Library of NMR Spectra*, both also by Pouchert. A similar volume, which has IR and Raman spectra of ~1000 compounds, is *Raman/Infrared Atlas of Organic Compounds*, 2nd ed., VCH, New York, **1989**, by Schrader.

15. An extensive list of visible and UV peaks is given in *Organic Electronic Spectral Data*, Wiley, New York. Twenty-six volumes have appeared so far, covering the literature through 1984.
16. A collection of 500 ^{13}C NMR spectra is found in Johnson and Jankowski, *Carbon-13 NMR Spectra*, Wiley, New York, 1972.

Reviews

A review article is an intensive survey of a rather narrow field; for example, the titles of some recent reviews are “Desulfonation Reactions: Recent Developments,”³¹ “Pyrrolizidine and Indolizidine Syntheses Involving 1,3-Dipolar Cycloaddition,”³² and “From Corrin Chemistry to Asymmetry Catalysis—A Personal Account.”³³ A good review article is of enormous value, because it is a thorough survey of all the work done in the field under discussion. Review articles are printed in review journals and in certain books. The most important review journals in organic chemistry (though most are not exclusively devoted to organic chemistry) are shown in Table A.3. Some of the journals listed in Table A.1, for

example, *Synlett*, *Tetrahedron*, *Synthesis*, *Organic Preparations and Procedures International*, and *J. Organomet. Chem.* also publish occasional review articles.

There are several open-ended serial publications that are similar in content to the review journals, but are published irregularly (seldom more often than once a year) and are hardbound. Some of these publish reviews in all fields of chemistry; some cover only organic chemistry; some specialize further. The coverage is indicated by the titles. Table A.4 shows some of the more important such publications, with *CA* abbreviations.

There are several publications that provide listings of review articles in organic chemistry. The most important is the *J. Org. Chem.*, which began to list review articles in 1978 (the first list is at *J. Org. Chem.*, 43, 3085), suspended the listings in 1985, and resumed them in 1990 (at *J. Org. Chem.*, 55, 398). These lists, which appear about four times a year, give the titles and reference sources of virtually

all review articles in the field of organic chemistry that have appeared in the preceding 3 months, including those in the review journals and serials mentioned above, as well as those in monographs and treatises. There is also a listing of new monographs on a single subject. Each list includes a subject index.

Another publication is the *Index of Reviews in Organic Chemistry*, compiled by Lewis, Chemical Society, London, a classified listing of review articles. The first volume, published in 1971, lists reviews from ~1960 (in some cases much earlier) to ≈ 1970 in alphabetical order of topic. Thus four reviews are listed under “Knoevenagel condensation,” five under “Inclusion compounds,” and one under “Vinyl ketones.” There is no index. A second volume (1977) covers the literature to 1976. Annual or biannual supplements appeared from 1979 until the publication was terminated in 1985. Classified lists of review articles on organometallic chemistry are found in articles by Smith and Walton³⁶ and by Bruce.³⁷ A similar list for heterocyclic chemistry is found in articles by Katritzky and others.³⁸ See also the discussion of the *Index of Scientific Reviews*, p. 1908.

Annual Reviews

The review articles discussed in the previous section are each devoted to a narrow topic covering the work done in that area over a period of years. An annual review is a publication that covers a broad area, but limits the period covered, usually to 1 or 2 years.

1. The oldest annual review publication still publishing is *Annual Reports on the Progress of Chemistry*, published by the Royal Society of Chemistry (formerly the chemical Society), which began in 1905 and which covers the whole field of chemistry. Since 1967 it has been divided into sections. Organic chemistry is found in Section B.
2. Because the number of papers in chemistry has become so large, the Royal Society of Chemistry publishes annual-review-type volumes of smaller scope, called *Specialist Periodical Reports*. Among those of interest to organic chemists are “Carbohydrate Chemistry” (Vol. 22 covers 1988); “Photochemistry” (Vol. 21 covers 1988–1989); and “General and Synthetic Methods,” (Vol. 12 covers 1987).
3. *Organic Reaction Mechanisms*, published by Wiley, New York, is an annual survey that covers the latest developments in the field of mechanisms. The first volume, covering 1965, appeared in 1966.
4. There are two annual reviews devoted to progress in organic synthesis. Theilheimer, *Synthetic Methods of Organic Chemistry*, S. Karger Verlag,

³⁶Smith, J.D.; Walton, D.R.M. *Adv. Organomet. Chem.* **1975**, *13*, 453.

³⁷Bruce, M.I.K. *Adv. Organomet. Chem.* **1972**, *10*, 273, **1973**, *11*, 447, **1974**, *12*, 380.

³⁸Belen'kii, L.I. *Adv. Heterocyclic Chem.* **1988**, *44*, 269; Katritzky, A.R.; Jones, P.M. *Adv. Heterocyclic Chem.* **1979**, *25*, 303; Katritzky, A.R.; Weeds, S.M. *Adv. Heterocyclic Chem.* **1966**, *7*, 225.

Basel, is an annual compilation, beginning in 1946, of new methods for the synthesis of organic compounds, arranged according to a system based on bond closing and bond breaking reactions. Equations, brief procedures, yields, and literature references are given. Volume 44 was issued in 1990. Volumes 3 and 4 are available only in German, but all the rest are in English. There is an index to each volume. Cumulative indexes appear in every fifth volume. Beginning with Vol. 8, each volume includes a short summary of trends in synthetic organic chemistry. A more recent series is *Annual Reports in Organic Synthesis*, Academic Press, New York, which has covered the literature of each year since 1970. Equations are listed with yields and references according to a fairly simple system.

5. The *Journal Of Organometallic Chemistry* several times a year publishes annual surveys arranged according to metallic element. For example, Vol. 404, published in February 1991, contains annual surveys for 1989 of organic compounds containing Sb, Bi, and Fe, and the use of transition metals in organic synthesis, and surveys for 1988 covering B, Ru, and Os.

Awareness Services

Besides the annual reviews and the title and abstract services previously mentioned, there exist a number of publications designed to keep readers aware of new developments in organic chemistry or in specific areas of it.

1. *Chemtracts: Organic Chemistry* is a bimonthly periodical, begun in 1988, that prints abstracts of certain recently published papers (those that the editors consider most important), with commentaries on these papers by distinguished organic chemists. Important current research in bioorganic, organometallic, synthesis, physical-organic and theoretical chemistry, and pharmaceutical–medicinal chemistry is covered in each issue, giving readers updates on the newest trends and developments in organic chemistry by summarizing and commenting on current and past research..
2. The Institute for Scientific Information (ISI), besides publishing *Current Contents* (p. 1877) and the *Science Citation Index* (p. 1877), also publishes *Index Chemicus* (formerly called *Current Abstracts of Chemistry and Index Chemicus*). This publication, begun in 1960 and appearing weekly, is devoted to printing structural formulas of all new compounds appearing in >100 journals, along with equations to show how they were synthesized and an author's summary of the work. Each issue contains five indexes: author, journal, biological activity, labeled compounds, and intermediates that were not isolated. These indexes are cumulated annually.
3. Theilheimer and the *Annual Reports on Organic Synthesis*, mentioned in the previous section, list new synthetic methods once a year. There are several publications that do this monthly. Among these are *Current Chemical Reactions* (begun in 1979 and published by ISI), *Journal of Synthetic*

Methods (begun in 1975 and published by Derwent publications), and *Methods in Organic Synthesis*, begun in 1984 and published by the Royal Society of Chemistry. *Methods in Organic Synthesis* also lists books and review articles pertaining to organic synthesis.

4. *Natural Product Updates*, a monthly publication begun in 1987 and published by the Royal Society of Chemistry, lists recent results in the chemistry of natural products, along with structural formulas. It covers new compounds, structure determinations, new properties and total syntheses, among other topics.

General Treatises

There are a number of large-scale multivolume treatises that cover the whole field of organic chemistry or large areas of it.

1. *Rodd's Chemistry of Carbon Compounds*, edited by Coffey, Elsevier, Amsterdam, The Netherlands, is a treatise consisting of five main volumes, each of which contains several parts. publication began in 1964 and is not yet complete. The organization is not greatly different from most textbooks, but the coverage is much broader and deeper. Supplements to many of the volumes have appeared. An earlier edition, called *Chemistry of Carbon Compounds*, edited by Rodd, was published in 10 parts from 1951 to 1962.
2. Houben–Weyl's, *Methoden der Organischen Chemie*, Georg Thieme Verlag, Stuttgart, is a major treatise in German devoted to laboratory methods. The fourth edition, which was begun in 1952 and consists of 20 volumes, most of them in several parts, is edited by E. Muller. The series includes supplementary volumes. The first four volumes contain general laboratory methods, analytical methods, physical methods, and general chemical methods. The later volumes are devoted to the synthesis of specific types of compounds, for example, hydrocarbons, oxygen compounds, and nitrogen compounds. Beginning in 1990 parts of the series have appeared in English.
3. *Comprehensive Organic Chemistry*, Pergamon, Elmsford, NY, 1979, is a six-volume treatise on the synthesis and reactions of organic compounds. The first three volumes cover the various functional groups, Vol. 4, heterocyclic compounds, and Vol. 5, biological compounds, such as proteins, carbohydrates, and lipids. Probably the most useful volume is Vol. 6, which contains formula, subject, and author indexes, as well as indexes of reactions and reagents. The last two of these not only refer to pages within the treatise, but directly give references to review articles and original papers. For example, on p. 1129, under "Chromic acid-sulphuric acid (Jones reagent), oxidation, alcohols," are listed 13 references to original papers. Several similar treatises, including the nine-volume *Comprehensive Organometallic Chemistry* (1982), the eight volume *Comprehensive Heterocyclic Chemistry* (1984), and the six volume *Comprehensive Medicinal Chemistry* (1989) are also published by Pergamon. The indexes to these works also include references.

4. A major treatise devoted to experimental methods of chemistry is *Techniques of Chemistry*, edited first by Weissberger and then by Saunders, Wiley, New York. This publication, which began in 1970, so far consists of 21 volumes, most of them in several parts, covering such topics as electrochemical and spectral methods, kinetic methods, photochromism, and organic solvents. *Techniques of Chemistry* is a successor to an earlier series, called *Techniques of Organic Chemistry*, which appeared in 14 volumes, some of them in more than one edition, from 1945 to 1969.
5. *Comprehensive Chemical Kinetics*, edited by Bamford and Tipper, 1969–, Elsevier, Amsterdam, The Netherlands, is a multivolume treatise covering the area of reaction kinetics. Six of these volumes (not all published at the time of writing) deal with the kinetics and mechanisms of organic reactions in a thorough and comprehensive manner.
6. Three multivolume treatises that cover specific areas are Elderfield, *Heterocyclic Compounds*, Wiley, New York, 1950–; Manske and Holmes, *The Alkaloids*, Academic Press, New York, 1950–; and Simonson, Owen, Barton, and Ross, *The Terpenes*, Cambridge University Press, London, 1947–1957.
7. *Encyclopedia of Reagents for Organic Synthesis*, edited by Paquette, Wiley, New York, was published in 1995. It is an eight volume, alphabetic listing of reagents used in organic chemistry with descriptions of the preparation, use and chemistry, with references. Each reagent was researched by organic chemists active in research, who contributed to the total publication.

This work is available on-line as **eEROS**. The *Encyclopedia of Reagents for Organic Synthesis*, e-EROS, provides updated information on ~3800 reagents with a database of close to 50,000 reactions. Each reagent entry includes properties such as physical data, solubility, form supplied in, purification, and preparative methods; examples of use in reactions; and literature references. Search options include: name, CAS number, structure and reaction.
8. *Comprehensive Organic Synthesis*, edited by Trost and Fleming, Pergamon, was published in 1991. It is a nine volume compilation.
9. *Comprehensive Organic Functional Group Transformations*, edited by Katritzky, Meth-Cohn, and Rees, Pergamon, was published in 1995. It is a seven volume compilation.

Monographs and Treatises on Specific Areas

Organic chemistry is blessed with a large number of books devoted to a thorough coverage of a specific area. Many of these are essentially very long review articles, differing from ordinary review articles only in size and scope. Some of the books are by a single author, and others have chapters by different authors but all are carefully planned to cover a specific area. Many of these books have been referred to in footnotes in appropriate places in this book. There have been several series of monographs, one of which is worth special mention: *The Chemistry of Functional Groups*, under the general editorship of Patai, published by

Wiley, New York. Each volume deals with the preparation, reactions, and physical and chemical properties of compounds containing a given functional group. Volumes covering >20 functional groups have appeared so far, including books on alkenes, cyano compounds, amines, carboxylic acids and esters, and quinones.

Textbooks

There are many excellent textbooks in the field of organic chemistry. We restrict ourselves to listing only a few of those published, mostly since 1985. Some of these are first-year texts and some are advanced (advanced texts generally give references; first-year texts do not, though they may give general bibliographies, suggestions for further reading, etc.); some cover the whole field, and others cover reactions, structure, and/or mechanism only. All the books listed here are not only good textbooks and the advanced books are valuable reference books for graduate students and practicing chemists.

Bruckner, *Advanced Organic Chemistry: Reaction Mechanisms*, Academic Press, NY **2001**.

Bruice, *Organic Chemistry*, 4th ed., Prentice-Hall, NJ, **2004**.

Carey, *Organic Chemistry*, 6th ed., McGraw-Hill, NY, **2006**.

Carey and Sundberg, *Advanced Organic Chemistry: Structure and Mechanisms (Part A)*, 4th ed., Springer, **2004**.

Carey and Sundberg, *Advanced Organic Chemistry: Structure and Mechanisms (Part B)*, 4th ed., Springer, **2001**.

Carruthers and Coldham, *Some Modern Methods of Organic Synthesis*, 4th ed., Cambridge University Press, Cambridge, **2004**.

Ege, *Organic Chemistry: Structure and Reactivity*, 5th ed., D.C. Houghton Mifflin, Boston, **2003**.

Fox and Whitesell, *Organic Chemistry*, 3rd ed, Jones and Bartlett, Sudbury, MA, **2004**.

- Sykes, *A Guidebook to Mechanism in Organic Chemistry*, 6th ed., Longmans Scientific and Technical, Essex, **1986**.
- Vollhardt and Schore, *Organic Chemistry*, 4th ed., W.H. Freeman, New York, **2002**.
- Wade, *Organic Chemistry*, 4th ed., Prentice-Hall, Upper Saddle River, NJ, **1999**.

Other Books

In this section, we mention several books that do not fit conveniently into the previous categories. All but the last have to do with laboratory synthesis.

1. *Organic Syntheses*, published by Wiley, New York is a collection of procedures for the preparation of specific compounds. The thin annual volumes have appeared each year since 1921. For the first 59 volumes, the procedures for each 10- (or 9-) year period are collected in cumulative volumes. Beginning with Vol. 60, the cumulative volumes cover five-year periods. The cumulative volumes published so far are

Annual Volumes	Collective Volumes
1-9	I
10-19	II
20-29	III
30-39	IV
40-49	V
50-59	VI
60-64	VII
65-69	VIII
70-74	IX
75-80	X

The advantage of the procedures in *Organic Syntheses*, compared with those found in original journals, is that these procedures are *tested*. Each preparation is

carried out first by its author, and then by a member of the *Organic Syntheses* editorial board, and only if the yield is essentially duplicated is the procedure published. While it is possible to repeat most procedures given in journals, this is not always the case. All *Organic Syntheses* preparations are noted in *Beilstein* and in *CA*. In order to locate a given reaction in *Organic Syntheses*, the reader may use the OS references given in the present volume (through OS 69); the indexes in *Organic Syntheses* itself; Shriner and Shriner, *Organic Syntheses* Collective Volumes I, II, III, IV, V *Cumulative Indices*, Wiley, New York, 1976, or Sugasawa and Nakai; Reaction Index of *Organic Syntheses*, Wiley, New York, 1967 (through OS 45). Another book classifies virtually all the reactions in *Organic Syntheses* (collective vols. I–VII and annual vols. 65–68) into 11 categories: annulation, rearrangement, oxidation, reduction, addition, elimination, substitution, C–C bond formation, cleavage, protection–deprotection, and miscellaneous. This is *Organic Syntheses: Reaction Guide*, by Liotta and Volmer, published by Wiley, New York, in 1991. Some of the categories are subdivided further, and some reactions are listed in more than one category. What is given under each entry are the equation and the volume and page reference to *Organic Syntheses*.

2. Volume 1 of *Reagents for Organic Synthesis*, by Fieser and Fieser, Wiley, New York, 1967, is a 1457–page volume that discusses, in separate sections, some 1120 reagents and catalysts. It tells how each reagent is used in organic synthesis (with references) and, for each, tells which companies sell it, or how to prepare it, or both. The listing is alphabetical. Eighteen additional volumes have so far been published, which continue the format of Vol. 1 and add more recent material. A cumulative index for Vols. 1–12, by Smith and Fieser, was published in 1990. A complete cumulative index for Vol. 1–22 was published in 2005, by M.B. Smith. The series included Vol. 1–18 with Mary Fieser. After the death of Mary Fieser, the series was resumed by T. -L. Ho, and now includes Vol. 19–22.
3. *Comprehensive Organic Transformations*, 2nd ed. by Larock, Wiley-VCH, New York, 1999, has been frequently referred to in footnotes in Part 2 of this book. This compendium is devoted to listings of methods for the conversion of one functional group into another, and covers the literature through 1987. It is divided into nine sections covering the preparation of alkanes and arenes, alkenes, alkynes, halides, amines, ethers, alcohols and phenols, aldehydes and ketones, and nitriles, carboxylic acids and derivatives. Within each section are given many methods for synthesizing the given type of compound, arranged in a logical system. A schematic equation is given for each method, and then a list of references (without author names, to save space) for locating examples of the use of that method. When different reagents are used for the same functional group transformation, the particular reagent is shown for each reference. There is a 164–page index of group transformations. The 2nd edition has only recently been published and is *not* referenced in this edition, and a CD ROM version is now available.

4. *Survey of Organic Synthesis*, by Buehler and Pearson, Wiley, New York, 2 vols., **1970, 1977**, discusses hundreds of reactions used to prepare the principal types of organic compounds. The arrangement is by chapters, each covering a functional group, (e.g., ketones, acyl halides, amines). Each reaction is thoroughly discussed and brief synthetic procedures are given. There are many references.
5. A similar publication is Sandler and Karo, *Organic Functional Group Preparations*, 2nd ed., 3 vols., Academic Press, New York, **1983–1989**. This publication covers more functional groups than Buehler and Pearson.
6. *Compendium of Organic Synthetic Methods*, Wiley, New York, contains equations describing the preparation of thousands of monofunctional and difunctional compounds with references. Eleven volumes have been published so far (vol. 1–2, edited by Harrison and Harrison; Vol. 3, edited by Hegedus and Wade; Vol. 4–5, edited by Wade; Vol. 6–11 edited by Smith). Volume 12 will appear in 2007.
7. *The Vocabulary of Organic Chemistry*, by Orchin, Kaplan, Macomber, Wilson, and Zimmer, Wiley, New York, **1980**, presents definitions of >1000 terms used in many branches of organic chemistry, including stereochemistry, thermodynamics, wave mechanics, natural products, and fossil fuels. There are also lists of classes of organic compounds, types of mechanism, and name reactions (with mechanisms). The arrangement is topical rather than alphabetical, but there is a good index. *Compendium of Chemical Terminology*, by Gold, Loening, McNaught, and Sehmi (the “Gold book”), published by Blackwell Scientific publications, Oxford, in 1987, is an official IUPAC list of definitions of terms in several areas of chemistry, including organic.

LITERATURE SEARCHING

Until recently searching the chemical literature meant looking only at printed materials (some of which might be on microfilm or microfiche). Now, however, much of the literature can be searched online, including some of the most important. Whether the search is online or uses only the printed material, there are two basic types of search, (1) searches for information about one or more specific compounds or classes of compounds, and (2) other types of searches. First, we will discuss searches using only printed materials, and then on-line searching.³⁹

Literature Searching Using Printed Materials

Searching for Specific Compounds. Organic chemists often need to know if a compound has ever been prepared and if so, how, and/or they may be seeking a melting point, an ir spectrum, or some other property. Someone who wants all

³⁹For a monograph that covers both online searching and searching using printed materials, see Wiggins, *G. Chemical Information Sources*, McGraw-Hill: NY, **1991**.

the information that has ever been published on any compound begins by consulting the formula indexes in *Beilstein* (p. 1883). At this time there are two ways to do this. (1) The formula index to the second supplement (Vol. 29, see p. \$\$\$) will quickly show whether the compound is mentioned in the literature through 1929. If it is there, the searcher turns to the pages indicated, where all methods used to prepare the compound are given, as well as all physical properties, with references. Use of the page heading method described on p. 1882 will then show the locations, if any, in the third and later supplements. (2) If one has an idea which volume of *Beilstein* the compound is in (and the tables of contents at the front of the volumes may help), one may search the cumulative index for that volume. If not sure, one may consult several indexes. One of these two procedures will locate all compounds mentioned in the literature through 1959. If the compound is heterocyclic, it may be in the fifth supplement. If it is in Vols. 17–19 (or in a later volume whose index has been published), the corresponding indexes may be consulted. If not, the page heading method will find it, if it was reported before 1960.⁴⁰ There is a way by which all of the above can be avoided. A computer program, called SANDRA (available from the *Beilstein* publisher), allows the user to find the *Beilstein* location by using a mouse to draw the structural formula of the compound sought. At this point, the investigator will know (1) all information published through 1959 or 1979,³⁴ or (2) that the compound is not mentioned in the literature through 1959 or 1979.⁴¹ In some cases, scrutiny of *Beilstein* will be sufficient, perhaps if only a boiling point or a refractive index is required. In other cases, especially where specific laboratory directions are needed, the investigator will have to turn to the original papers.

To carry the search past 1959 (or 1979), the chemist next turns to the collective formula indexes of *Chemical Abstracts*TM: 1957–1961; 1962–1966; 1967–1971; 1972–1976; 1977–1981; 1982–1986; 1987–1991; 1992–1996; 1997–2002, and such later collective indexes as have appeared; and the semiannual indexes thereafter. If a given formula index contains only a few references to the compound in question, the pages or abstract numbers will be given directly in the formula index. However, if there are many references, the reader will be directed to see the chemical substance index or (before 1972) the subject index for the same period; and here the number of page or abstract numbers may be very large indeed. Fortunately, numerous subheadings are given, and these often help the user to narrow the search to the more promising entries. Nevertheless, one will undoubtedly turn to many abstracts that do not prove to be helpful. In many cases, the information in the abstracts will be sufficient. If not, the original references must be consulted. In some cases (the index entry is marked by an asterisk or a double asterisk), the

⁴⁰Compounds newly reported in the fifth supplement that are in a volume whose index has not yet been published will not be found by this procedure. To find them in *Beilstein* it is necessary to know something about the system (see Ref. 25), but they may also be found by consulting *CA* indexes beginning with the sixth collective index, or by using *Beilstein* on-line.

⁴¹For those heterocyclic compounds that would naturally belong to a volume for which the fifth supplement has been published.

compound is not mentioned in the abstract, though it is in the original paper or patent. Incidentally, all entries in the *CA* indexes that refer to patents are prefixed by the letter P. Since 1967, the prefixes B and R have also been used, to signify books and reviews, respectively.

By the procedure outlined above, all information regarding a specific compound that has been published up to about 1 year before the search can be found by a procedure that is always straightforward and that in many cases is rapid (if the compound has been reported only a few times). Equally important, if the compound has not been reported, the investigator will know that, too. It should be pointed out that for common compounds, such as benzene, ether, acetone, trivial mentions in the literature are not indexed (so they will not be found by this procedure), only significant ones. Thus, if acetone is converted to another compound, an index entry will be found, but not if it is used as a solvent or an eluant in a common procedure.

The best way to learn if a compound is mentioned in the literature after the period covered by the latest semiannual formula index of *CA* is to use the online services. However, if one lacks access to these, one may consult the keyword index at the end of each issue of *CA*. In these cases, of course, it is necessary to know what name might be used for the compound. The name is not necessary for *Index Chemicus*; one consults the formula indexes. However, these methods are far from complete. *Index Chemicus* lists primarily new compounds, those that would not have been found in the earlier search. The keyword indexes in *CA* are more complete, being based on internal subject matter, as well as title, but they are by no means exhaustive. Furthermore, all three of these publications lag some distance behind the original journals. To locate all references to a compound after the period covered by the latest semiannual formula index of *CA*, it is necessary to use *CAS* on-line.

The complete procedure described above may not be necessary in all cases. Often all the information one needs about a compound will be found in one of the handbooks (p. 1887), in the *Dictionary of Organic Compounds* (p. 1885), or in one of the other compendia listed in this chapter, most of which give references to the original literature.

Other Searches.⁴² There is no definite procedure for making other literature searches using only printed materials. Any chemist who wishes to learn all that is known about the mechanism of the reaction between aldehydes and HCN, or which compounds of the general formula Ar_3CR have been prepared, or which are the best catalysts for Friedel–Crafts acylation of naphthalene derivatives with anhydrides, or where the group $-\text{C}(\text{NH}_2)=\text{N}-$ absorbs in the IR, is dependent on their ingenuity and knowledge of the literature. If a specific piece of information is needed, it may be possible to find it in one of the compendia mentioned previously. If the topic is more general, the best procedure is often to begin by consulting one or more monographs, treatises, or textbooks that will give general

⁴²This discussion is necessarily short. For much more extensive discussions, consult the books in Refs. 1 and 17.

background information and often provide references to review articles and original papers. In many cases, this is sufficient, but when a complete search is required, it is necessary to consult the *CA* subject and/or chemical substance indexes, where the ingenuity of the investigator is most required, for now it must be decided which words to look under. If one is interested in the mechanism of the reaction between aldehydes and HCN, one might look under “aldehydes,” or “hydrogen cyanide,” or even under “acetaldehyde” or “benzaldehyde,” and so on, but then the search is likely to prove long. A better choice in this case would be “cyanohydrin,” since these are the normal products and references there would be fewer. It would be a waste of time to look under “mechanism.” In any case, many of the abstracts would not prove helpful. Literature searching of this kind is necessarily a wasteful process. Of course, the searcher would not consult the *CA* annual indexes, but only the collective indexes as far as they go and the semiannual indexes thereafter. If it is necessary to search before 1907 (and even before 1920, since *CA* was not very complete from 1907 to ~1920), recourse may be made to *Chemisches Zentralblatt* and the abstracts in the *Journal of the Chemical Society*.

Literature Searching Online³⁹

Most of the *Chemical Abstracts*TM literature can be accessed using CAS databases on-line. The CAS registry⁴³ is the largest and most current database of chemical substance information in the world containing >26 million organic and inorganic substances and 56 million sequences. CAS is a team of scientists who provide digital information environment for scientific research and discovery and provides pathways to published research in the world's journal and patent literature back to the beginning of the twentieth century. Since 1907, CAS has indexed and summarized chemistry-related articles from >40,000 scientific journals, in addition to patents, conference proceedings and other documents pertinent to chemistry, life sciences and many other fields. In total, abstracts for >24 million documents are accessible online through CAS. Through the printed *CA*, *CA* on CD, STN, the CAS files distributed through licensed vendors, the SciFinder[®] and SciFinder ScholarTM desktop research tools, and the STN[®] Easy or STN[®] on the Web services, data produced by CAS is accessible to virtually any scientific researcher worldwide in industry, governmental research institutions, and academia.

Substance identification is a special strength of CAS. It is widely known as the CAS Registry, the largest substance identification system in existence. When a chemical substance, newly encountered in the literature, is processed by CAS, its molecular structure diagram, systematic chemical name, molecular formula, and other identifying information are added to the Registry and it is assigned a unique CAS Registry Number[®]. Registry now contains records for >26 million organic and inorganic substances and >56 million sequences.

The CAS REGISTRY contains >27 million organic and inorganic substances and >57 million sequences. A current count of substance records like this is

⁴³<http://www.cas.org/about.html>

updated daily on the CAS web site.⁴⁴ An important piece of information that assists in such a search is the CAS Registry Number[®]. Each substance in REGISTRY is identified by a unique numeric identifier called a CAS Registry Number[®].⁴⁵ “The CAS Registry Number[®] is a unique number assigned to a chemical by the Chemical Abstracts Service.⁴⁶ A fairly large collection of CAS numbers, with links to safety data for many chemicals, can be found at the listing of chemicals by CAS number at the Safety Home Page of the Physical and Theoretical Chemistry Laboratory at Oxford University.”⁴⁷ The CAS Registry Number[®] is a unique numeric identifier that designates only one substance, has no chemical significance, and is a link to finding information about a specific chemical substance. A CAS Registry Number[®] includes up to nine digits that are separated into three groups by hyphens. The first part of the number, starting from the left, has up to six digits; the second part has two digits. The final part consists of a single check digit.⁴⁸

CAS is located in Columbus, Ohio and is a division of the American Chemical Society. CAS can be contacted at Chemical Abstracts Service, 2540 Olentangy River Road, P.O. Box 3012, Columbus, Ohio 43210 (E-mail: help@cas.org).

Online searching means using a computer terminal to search a *database*. Although databases in chemistry are available from several organizations, STN[®] International (The Scientific & Technical Information Network) is important because it is comprehensive and available in many countries. STN[®] has dozens of databases, including many that cover chemistry and chemical engineering. To access these databases a chemistry department, a library, or an individual subscribes to STN[®] (for a nominal fee), and receives code numbers that will permit access to the system. Then all one needs is a computer and a modem. STN[®] charges for each use, depending on which databases are used, for how long, and what kind of information is requested. One of the nice features of STN[®] is that the same command language is used for all databases, so when one has mastered the language for one database, one can use it for all the others. In this section, we will discuss literature searching using CAS databases online, which is one of the databases available from STN. One thing that must be remembered is that *CAS databases online* is complete only from 1967 to the present,⁴⁹ so that searches for earlier abstracts must use the printed volumes. However, for the period since 1967, not only is online searching a great deal faster than searching the printed CA, but, as we will see, one can do kinds of searches online that are simply not possible using only the printed volumes. Furthermore, the on-line files are updated every two weeks, so that one will find all the abstracts on-line well past the appearance of the latest semiannual indexes, often even before the library has received the latest

⁴⁸<http://www.cas.org/EO/checkdig.html>

⁴⁹There is also a file called CAOLD that has some papers earlier than 1967.

weekly printed issue of *CA*. The *CAS databases online* is extremely flexible; one can search in a great many ways. It is beyond the scope of this book to discuss the system in detail (*CA* conducts workshops on its use), but even with the few commands we will give here, a user can often find all that he or she is looking for. The *CAS databases online* has two major files, the *CA File* and the *Registry File*.⁵⁰ T

SciFinder[®]: A Search Tool for Exploring CAS Databases⁵¹

Tutorials are available to help use SciFinder[®],⁵² which is a searching tool and not the CAS database. SciFinder[®] can search a research topic⁵³ or a compound can be searched by structure.⁵⁴ Another search engine is available, different from SciFinder[®], known as STN Express[®] with Discover!,⁵⁵ and this searching tool can also be used to search CAS databases.⁵⁶ The Analysis Edition of STN Express[®] with Discover! allows one to search, analyze, visualize, and discover sci-tech information by the ability to create a table for substance analysis that identifies the common substructure for an answer set of structurally related substances; Group related author-inventor names and company names for better analysis and visualization results; Analyze and tabulate data from single- or multi-file search results, and create a data table and 3D chart; Save an answer set from databases such as CPlusSM, PCTFULL, and USPATFULL with the Save for STN[®] AnaVist Wizard, and then import and open it in STN[®] AnaVistTM; Create an interactive spreadsheet from all or only hit CAS Registry Number[®]s and their corresponding CAS Roles through the CAS Registry Number[®]; Upload lengthy genetic sequences automatically for searching in DGENE and PCTGEN via the Upload Query Wizard. STN Express[®] was developed in collaboration with Hampden Data Services. Note that the CPlus database makes it possible to see not only what a paper has cited, but also what papers it been cited by.

To illustrate how STN[®] is used, an on-line tutorial is available.⁵⁷ A few on-line windows from a SciFinder[®] search are provided to illustrate how searches can be done. This presentation is by no means complete or intended as an alternative to the actual tutorial. Indeed, one could *not* use SciFinder[®] properly after simply reading this discussion. The intent is to illustrate some features that are available and to present an overview of the use of this important tool.

⁵⁰There is also a file, LCA, which is used for learning the system. It includes only a small fraction of the papers in the CA File, and is not updated. There is no charge for using the LCA File, except for a small hourly fee.

⁵¹<http://www.cas.org/>. For a tutorial, see <http://www.cas.org/SCIFINDER/citation.html>.

Fig. A.3. Explore by research topic.

Using SciFinder[®], a search can be done in one of several different ways. In one example, a search is done by research topic.⁵⁸ The example shown in Fig. A.3 shows a search for intramolecular hydroamination of aminoalkenes. To begin, click Explore by research topic and enter the appropriate information.

It is possible to use filters (see Fig. A.3) in order to refine the search by year, document type (journal, patent, review, etc.), author, or company. A window is returned containing references categorized by their relationship to the search phrase, as shown in Fig. A.4. One then simply checks those reference lists that appear closest to the area of interest.

After clicking on “get references,” a screen is returned (Fig. A.5) that has the original references as shown in the window. One is given the option of refining this list further, and for each reference, most browsers allow viewing of the abstract or the full references as an HTML or a pdf file. Two icons appear beside each reference in the list: a microscope, which can be clicked on to see the abstract, and an document icon that can be clicked on to see the full-text, original article on the publisher’s web-site. This feature is an alternative to document delivery in the traditional sense.

Other examples of typical searches allowed by SciFinder[®] include search by authors name, as with Professor K. Barry Sharpless shown in Fig. A.6. Search by structure is also possible, such as the one shown in Fig. A.7, and the program provides drawing tools. SciFinder[®] then searches to finds matches based on structure or reaction.

It is also possible to using the drawing tools to search by reaction and reaction type. SciFinder[®] returns reaction information, such as that shown in Fig. A. 8. In

⁵⁸<http://www.cas.org/SCIFINDER/topic.html>

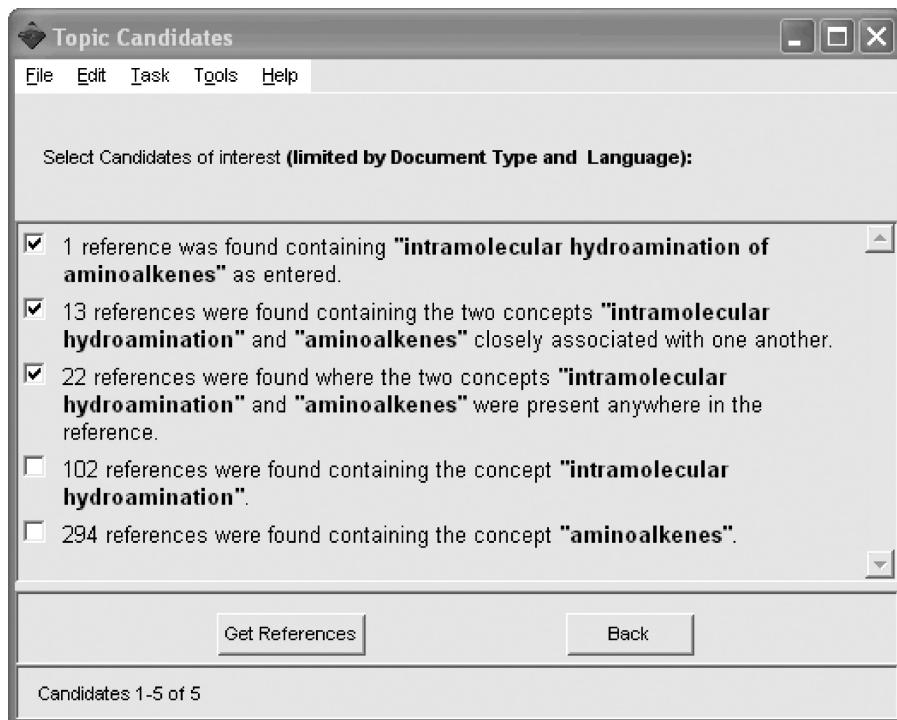

Fig. A.4. Selection of candidates of interest for search by research topic.

all cases, journal articles and/or patents are returned that provide direct access to the literature of interest.

Science Citation Index

As seen in the SciFinder[®] search tutorials, it is possible to track papers that have cited a particular article or author. A publication that can greatly facilitate literature searching is *Science Citation Index (SCI)*, begun in 1961. This publication, which is quite different from any other mentioned in this chapter, gives a list of all papers in a given year that have cited a given paper, patent, or book. Its utility lies in the fact that it enables the user to search *forward* from a given paper or patent, rather than backward, as is usually the case. For example, suppose a chemist is familiar with a paper by Jencks and Gilchrist (*J. Am. Chem. Soc.*, **1968**, *90*, 2622) entitled “Nonlinear Structure–Reactivity Correlations. The Reactivity of Nucleophilic Reagents toward Esters.” The chemist is easily able to begin a search for earlier papers by using references supplied in this paper, and can then go further backward with the aid of references in those papers, and so on. But for obvious reasons, the paper itself supplies no way to locate *later* papers.

References 1-5 of 22

Fig. A.5. Original literature references returned for search by research topic.

The *SCI* is designed to make up for this gap. The citation index of *SCI* lists all papers, patents, or books cited in a given year or 2-month period (by first author only) and then gives a list of papers that have done the citing. The index is published bimonthly and cumulated annually. For example, column 43,901 of the 1989 citation index shows that the Jencks paper mentioned above was cited as a footnote in 16 papers published in 1989. It is reasonable to assume that most of the papers that cited the Jencks paper were on closely related subjects. For each of the 16 papers are listed the first author, journal abbreviation, volume and page numbers, and year. In a similar manner, if one consulted *SCI* for all the years from 1968 on, one would have a complete list of papers that cited that paper. One could obviously broaden the search by then consulting *SCI* (from 1989 on) for papers that cited these 16 papers, and so on. Papers, patents, or books listed, for example, in the 1989 *SCI* may go back many years (e.g., papers published by Einstein in 1905 and 1906 are included). The only

The screenshot shows a dialog box titled "Explore by Author Name" with a close button (X) in the top right corner. The dialog contains the following elements:

- Enter the author's name.**
- Last name (required):
- First name or initial:
- Middle name or initial:
- Look for alternative spellings of the last name.
- Buttons: OK and Cancel.

Fig. A.6. Screen shot for beginning a search by author.

requirement is that a paper published in 1989 (or late 1988) has mentioned the earlier paper in a footnote. The arrangement of cited papers or books is alphabetical by cited first author and then by cited year. Cited patents are listed in a separate table, in order of patent number, though the inventor and country are also given.

The *SCI* covers ~3200 journals in the physical and biological sciences, as well as in medicine, agriculture, and technology. In addition to the citation index, each bimonthly and annual *SCI* also includes three other indexes. One of these, called *Source Index*, is similar to the *CA* author index. It lists the titles, journal abbreviations, volume, issue, page numbers, and year of all papers published by a given author during that 2-month period or year. All authors are listed; not just first authors. The second, called the *Corporate Index*, lists all publications that have been published from a given institution during that period, by first author. Thus, the corporate index for 1989 lists 63 papers by 45 different first authors emanating from the Department of Chemistry of Rutgers University, New Brunswick, NJ. The main section of the corporate index (the Geographic Section) lists institutions by country or (for the U.S.) by state. There is also an Organization Section, which lists the names of institutions alphabetically, and for each gives the location, so it can be found in the geographic section. The third index included in *SCI* is the *Permuterm*⁵⁹ *Subject Index*. This index alphabetically lists every significant word in the titles of

⁵⁹Registered trade name.

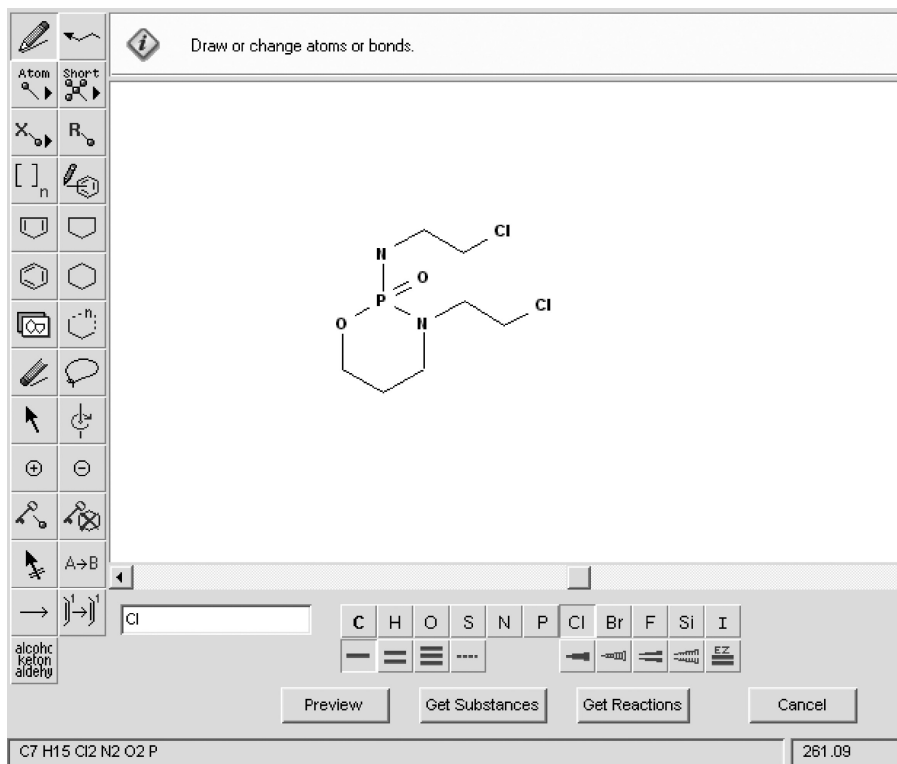

Fig. A.7. Screen shot for beginning a search by structure, using the drawing tools.

all papers published in that year or bimonthly period, paired with all other significant words in the same title. Thus, for example, a title with seven significant words appears at 42 separate places in the index. Each of the seven words appears six times as the main word, each time paired with a different word as the coword. The user is then led to the *Source Index*, where the full reference is given. The *SCI* is also available on-line (though not through STN) and on CD ROM disks. A version of *SCI* that is restricted to chemistry, but also includes searchable abstracts, is available only in the CD ROM format.

The publishers of *SCI* also produce another publication, called *Index to Scientific Reviews*, that appears semiannually. This publication, which began in 1974, is very similar to *SCI*, but confines itself to listing citations to review articles. The citations come from ~2500 journals in the same general areas as are covered by *SCI*. The review articles cited appeared in ~215 review journals and books, as well as in those journals that publish occasional review articles. Like *SCI*, the *Index to Scientific Reviews* contains citation, source, corporate, and Permuterm indexes. It also contains a "Research Front Specialty Index," which classifies reviews by subject.

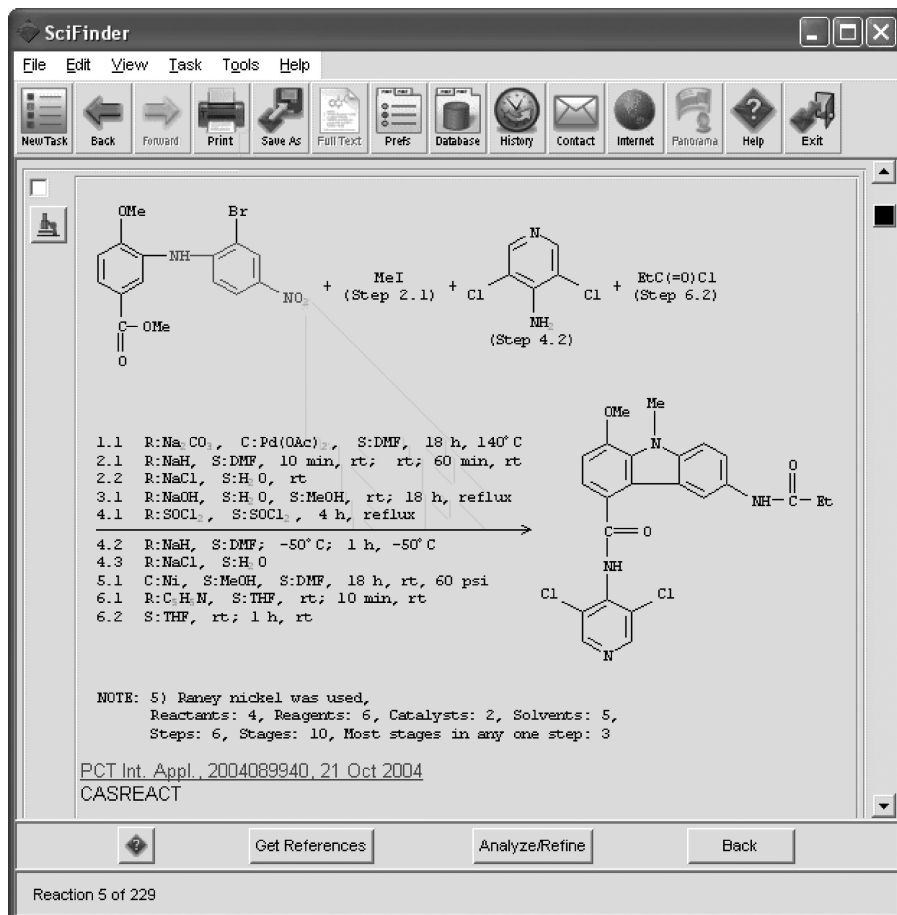

Fig. A.8. Screen shot of results for a search by reaction, using the drawing tools.

How to Locate Journal Articles

Having obtained a reference from various sources or searches, one often needs to consult the original journal (the location of patents is discussed on p. \$\$\$). The first step is to ascertain the full name of the journal, since it is the abbreviation that is generally given. Of course, everyone should be familiar with the abbreviations of the very important journals, such as *J. Org. Chem.*, *Angew. Chem. Int. Ed.*, and so on, but references are often found to journals whose titles are not at all familiar (e.g., *K. Skogs Lantbruksakad. Tidskr.* or *Nauchn. Tr. Mosk. Lesotekh. Inst.*). In such cases, one consults the *Chemical Abstracts Service Source Index (CASSI)*, with the most recent abbreviations in bold print. *CASSI* is available in a 1907–2004 cumulative, containing information 80,000 serial and nonserial publications. *CASSI* also lists journals covered by *Chemisches Zentralblatt* and its predecessors

from 1830 to 1969, and journals cited in *Beilstein* before 1907. The journals are listed in alphabetical order of the *abbreviations*, not of the titles. Journal title changes have not been infrequent, and *CASSI* also contains all former names, with cross-references to the current names. Quarterly supplements, cumulated annually, to *CASSI* have appeared since 1990 listing new journals and recent changes in journal titles. It should be pointed out that, while many publications use the *CA* abbreviations, not all do. The student will find that usage will vary from country to country, and even from journal to journal within a country. Furthermore, the *CA* abbreviations have changed from time to time. Articles can be accessed directly from SciFinder[®] using the CAS ChemPort feature.⁶⁰

Once the complete title is known, the journal can easily be obtained if it is in the library customarily used by the chemist. If not, one must use another library, and the next step is to find out which libraries carry the journal. *CASSI* answers this question too, since it carries a list of some 360 libraries in the United States and other countries, and *for each journal it tells which of these libraries carries it*, and furthermore, if the holdings are incomplete, which volumes of that journal are carried by each library. It may be possible to visit the closest library personally. If not, a copy of the article can usually be obtained through interlibrary loan. *CASSI* also includes lists of journal publishers, sales agents, and document depositories. Photocopies of most documents cited in *CA* can be obtained from *Chemical Abstracts*[™] Document Delivery Service, Customer Services, 2540 Olentangy River Road, Columbus OH, 43210, U.S. Orders for documents can be placed by mail, telephone, Telex, fax, or on-line through STN[®] or other services.

These latter comments are largely out of date given the on-line status of most journals. As mentioned above, pdf files of an article can be downloaded, or they can be read directly via the HTML file using any current browser. The reader is encouraged to contact the library person in your establishment that is responsible for chemical literature and to learn which on-line services are available through your local library.

Classification of Reactions by Type of Compounds Synthesized

ACETALS		boranes + CO–oxidation	18-23
acetals + RM	10-64	boranes + CO–reduction	18-24
aldehydes + alcohols	16-05	by the Cannizzaro reaction	19-81
by transesterification	10-13	by Wittig rearrangement	18-21
from dihalides	10-8	cleavage of ethers	10-49
from hydroxy-ethers	14-06	condensation of aldehydes	19-81
ortho esters + RM	10-64	conjugate reduction	15-14
reductive cleavage of ortho esters	19-56	carboxylic esters + organometallics	16-82
		epoxides + organometallics	10-65
ACYLALS (DIESTERS)		epoxides + silanes	10-55
aldehydes + anhydrides	16-06	from boranes	10-01
		from boronates	18-23
ACYLOINS – see hydroxy ketones		Grignard addition to aldehydes or ketones	16-24
ALCOHOLS		hydration of alkenes	15-03
addition of other organometallics to carbonyls	16-25	hydrolysis of acetals and ketals	10-06
aldehydes + allylic silanes	16-51	hydrolysis of alkyl halides	10-01
alkenes + alcohols	15-33	hydrolysis of inorganic esters	10-04
alkenes + aldehydes or ketones	16-54	hydrolysis of sulfonate esters	10-04
alkenes-oxymercuration	15-03	hydrolysis of vinyl ethers	10-06
amides + organometallic compounds	16-82	hydroxylation at aliphatic carbon	19-14
amines + KOH	10-23	hydroxymethylation of arenes	11-12
anhydrides + organometallic compounds	16-82	organolithium addition to aldehydes or ketones	16-24
arylation of ketones	11-12	oxidation of boranes	12-27
		oxidation of boranes	15-16
		oxidation of methylene	19-15

oxidation of silanes	10-16	boranes + MeO(ArS)CH ₂ Li	18-24
radical addition to carbonyl compounds	16-56	by decarboxylation	12-40
		by Michael addition	15-24
rearrangement of ethers	18-22	by rearrangement of aldehydes	18-04
rearrangement of peroxides	18-20	by the Wacker process	19-25
reduction of acyl halides	19-63	carbonylation of aromatic compounds	11-18
reduction of aldehydes or ketones	19-36	carbonylation of hydrocarbons	12-33
reduction of carbonyls with Grignard reagents	16-24	formylation of aromatic compounds	11-18
reduction of carboxylic acids	19-37	from aryl imines	11-18
reduction of carboxylic esters	19-38	from dihydrooxazines	10-72
reduction of carboxylic esters	19-65	from dithioaldehydes	16-11
reduction of epoxides	19-35	hydroformylation	15-37
reduction peroxides	19-60	hydrolysis of acetals	10-06
ring expansion of amines	18-03	hydrolysis of C=N compounds	16-02
silanes + aldehydes or ketones	16-26	hydrolysis of <i>gem</i> -dihalides	10-02
		hydrolysis of nitro compounds	16-03
ALCOHOLS, ALLYLIC		hydrolysis of vinyl ethers	10-06
addition of allylic organometallics to carbonyls	16-25	oxidation of alcohols	19-03
alkenes + formaldehyde	16-54	oxidation of aryl methyl groups	19-18
allylic silanes + aldehydes or ketones	16-26	oxidation of nitro compounds	19-21
deprotonation of epoxides	17-03	oxidation of primary alkyl halides	19-20
rearrangement of alkene-sulfoxides	18-35	oxidative cleavage of diols	19-07
		oxidative cleavage of epoxides	19-07
ALDEHYDES		ozonolysis of alkenes	19-09
alkenes + aldehydes	15-33	reduction anhydrides	19-40
alkyl halides + organoiron compounds	10-76	reduction nitriles	19-44
alkylation of aldehydes	10-68	reduction of acyl halides	19-39
alkylation of imines	10-68	reduction of acyl halides	19-40
alkylation reactions and keto-enol tautomerism	10-67	reduction of amides	19-41
aromatic compounds + chloroform	11-18	reduction of carboxylic acids	19-40
aromatic compounds + formaldehyde	11-18	reduction of carboxylic esters	19-40
aromatic compounds + formamides	11-18	ALKANES	
aromatic compounds + halo-ethers	11-18	addition of alkanes to alkenes	15-18
arylation of aldehydes	13-14	alcohols + RM	10-63
		alkenes + diimide	15-12
		alkenes + metals	15-12
		alkenes + organometallics	15-21
		alkyl halides + metals	10-56
		alkyl halides + metals	10-56
		alkyl halides + organocuprates	10-58
		alkyl halides + RM (Li, Na, K)	10-57

alkyl halides + RM (other metals)	10-59	replacement of metals in RM by hydrogen	12-24
alkyl halides + silanes	10-55	σ -bond rearrangements	18-38
Barton–McCombie reaction	19-58	sulfonate esters + metals	10-56
by decarboxylation	12-40	sulfonate esters + organocuprates	10-58
by [3+2]-cycloaddition	15-59	sulfonyl compounds + organometallics	10-61
cleavage of alkanes	12-47	via transmetallation	12-22
cleavage of ketones	12-46		
coupling of boranes	14-26	ALKENE-ALCOHOLS	
coupling of carboxylate salts	14-29	rearrangement of alkene-ethers	18-35
coupling of Grignard reagents	14-24		
coupling of organocuprates	14-25	ALKENE-ALDEHYDES	
coupling of two alkanes	14-15	Claisen rearrangement	18-33
decarbonylation of aldehydes	14-32	Cope rearrangement	18-32
decyanation	12-48	rearrangement of allyl vinyl ethers	18-33
from alcohols	19-58		
from alkylborates	10-59	ALKENE-ALKYNES	
from boranes	10-59	addition of alkynes to alkynes	15-20
hydrogen exchange	12-01		
hydrogenation of alkenes	15-11	ALKENE-AMINES	
hydrogenation of alkynes	15-11	rearrangement of alkene-ammonium salts	18-35
hydrogenation of aromatic compounds	15-13		
inorganic esters + RM	10-61	ALKENE-CARBOXYLIC ACIDS	
insertion by carbenes	12-21	Claisen rearrangement	18-33
pyrolysis of peroxides	17-37	rearrangement of alkene-esters	18-33
radical addition to alkenes	15-29		
radical coupling of alkanes	14-14	ALKENE-KETONES	
radical cyclization of alkenes	15-30	Claisen rearrangement	18-33
reduction dithioketals	10-71	rearrangement of allyl vinyl ethers	18-33
reduction of acyl halides	19-59		
reduction of alkyl halides	19-53	ALKENE-THIOETHERS	
reduction of carbonyls to methylene	19-61	rearrangement of alkene sulfonium salts	18-35
reduction of nitro compounds	19-67		
reduction of silanes	19-52	ALKENES	
reduction of sulfonate esters	19-57	1,3-elimination of diols	17-25
reduction of sulfur compounds	19-70	1,3-elimination of halo-amines	17-25
reduction of thioethers	14-27	1,3-elimination of halohydrins	17-25
reduction of thiols	14-27	addition of alkanes to alkynes	15-18
reduction of thiols	19-70	addition of alkenes to alkenes	15-20
reduction of xanthate esters	19-58

reduction of vinyl imines	19-61	ALLENES	
reductive coupling	19-77	base-induced rearrangement	18-03
of aldehydes or ketones		of halocyclopropanes	
reductive coupling of epoxides	19-35	by Claisen rearrangement	18-33
sigmatropic carbon migration	18-30	by the Wittig reaction	16-44
sigmatropic H migration	18-29	Cope rearrangement of di-yens	18-32
silyl-organometallics + aldehydes or ketones	16-41	elimination of dihalides	17-22
Tebbe alkenylation	16-45	propargylic esters + organocuprates	10-60
vinyl boranes + halogen/base	18-25	reduction of alkynes	19-53
vinyl halides + arylboronic acids	13-10	ALLOPHANATES	
vinyl-cyclopropane rearrangement	18-31	carbamates + isocyanates	16-08
vinyl-X + alkyl(aryl)boronic acids	12-15	AMIDE-ESTERS	
Wagner–Meerwein rearrangement of alcohols	18-01	aziridines + amides	10-14
Wagner–Meerwein rearrangement of halides	18-01	AMIDES	
ALKYNE-ALCOHOLS		acyl halides + ammonia or amines	16-72
addition of alkynes to carbonyls	16-25	addition of organometallics to isocyanates	16-33

alcohols + cyanogen halides	16-09	<i>N</i> -arylation	10-41
aldehydes + ammonia + oxidant	14-11	nitriles + alcohols	16-91
alkanes + nitriles	14-12	nitriles + amines	16-21
alkenes + amides	15-09	oxidation of methylene	19-17
alkenes + nitriles	16-91	in amines	
alkyl halides + amides	10-41	oxidation of methylene	19-17
alkylation of amides	19-73	in lactams	
amides + aldehydes	10-41	oximes + halogenating	18-17
amides + amines	16-76	or oxidizing agents	
amines + CO + alkenes	15-36	pyrolysis of imino esters	18-42
amines + CO	12-53	rearrangement of oximes	18-17
amines + haloformates	10-53	reduction of imides	19-64
amines + organoiron	10-77	transamidation	16-70
compounds			
amines + vinyl esters	16-75	AMIDINES	
anhydrides + ammonia	16-73	ketenimines + amines	15-08
or amines		nitriles + ammonia or amines	16-21
aromatic compounds + amides	11-22		
aromatic compounds +	11-06	AMINE OXIDES	
hydroxamic acids		oxidation of amines	19-29
aromatic compounds +	11-21		
isocyanates		AMINES	
aryl halides + amides	10-41	addition of organometallics	16-31
aryl halides + amides	13-05	to C=N compounds	
aryl halides, DMF and POCl ₃	11-21	addition of silanes to C=N	16-31
by Beckmann rearrangement	18-17	alkenes + amines or ammonia	15-08
by Michael addition	15-24	alkyl halides + amines	10-31
by the Willgerodt reaction	19-84	alkylation of amines	10-31
carboxylic acids +	16-74	alkylation of formamidines	10-71
amino-boranes		alkylation of nitroso amines	10-71
carboxylic acids and ammonia	16-74	amides + organometallic	16-82
or amines		compounds	
carboxylic esters + ammonia	16-75	amination of active methylene	12-12
or amines		compounds	
cleavage of ketones	12-46	amination of alkanes	10-39
condensation of methyl ketones	19-84	amination of alkanes	12-12
from alcohols	10-41	amination of methylene	19-16
hydrolysis of isonitriles	16-97	amines + aryl halides	13-05
hydrolysis of nitriles	16-04	amines + diaryliodonium	11-06
imines + borane + CO	12-33	compounds	
insertion of acyl nitrenes	12-13	amines + diazo compounds	10-34
insertion of diazo amides	12-21	aminomethylation of aromatic	11-22
ketenes + amines	15-08	compound	
ketones + HN ₃	18-16	aromatic compounds +	13-18
<i>N</i> -alkylation	10-41	amide bases	

aromatic compounds + aryl azides	11-06	rearrangement of ammonium salts	13-31
aromatic compounds + halo-amines	11-06	rearrangement of ammonium salts	18-21
aromatic compounds + hydrazoic acid	11-06	rearrangement of aryl hydroxylamines	13-32
aryl halides + alkyl organometallics	13-05	reduction nitroso compounds	19-47
aryl halides + hydroxylamine- <i>O</i> -sulfonic acid	18-15	reduction of amine oxides	19-68
azides + haloboranes	12-32	reduction of amines	19-64
aziridines + RM	10-66	reduction of azides	19-50
boranes + ammonia + NaOCl	12-32	reduction of azo compounds	19-74
boranes + chloramine	12-32	reduction of azoxy compounds	19-74
by the Stevens rearrangement	18-21	reduction of C=N compounds	19-42
by transamination	10-33	reduction of hydrazines	19-74
Curtius rearrangement	18-14	reduction of hydroxylamines	19-47
cyclization of halo-amines	18-40	reduction of isocyanates	19-51
dealkylation of amines	19-73	reduction of isothiocyanates	19-51
displacement of cyano	10-62	reduction of lactams	19-64
diynes + amines	15-08	reduction of nitriles	19-43
enamines + boranes	15-16	reduction of nitriles	19-45
from alcohols	10-31	reduction of nitro compounds	19-45
from alcohols	10-32	reduction of nitroso-amines	19-51
from amides	18-13	reduction oximes	19-48
from amines	10-33	reductive alkylation of aldehydes or ketones	16-17
from amino-nitriles	10-62	Schmidt reaction	18-16
from boranes	10-31		
from cyanohydrins	10-32	AMINO-ACIDS	
from ethers	10-32	lactones + ammonia or amines	16-75
from halo-amines	10-31	AMINO-ALCOHOLS :	
Hofmann rearrangement	18-13	see hydroxy-amines	
hydrolysis of isocyanates	18-13	AMINO-ALDEHYDES	
hydrolysis of isocyanates	18-15	aldehydes + C=N compounds	16-31
hydrolysis of isocyanates	18-16	AMINO-ESTERS	
hydroxylamines + alkyl organometallics	12-32	diazoesters + amines	15-64
insertion of nitrenes	12-13	AMINO-ETHERS	
Lossen rearrangement	18-15	aziridines + alcohols	10-14
Michael addition	15-31	AMINO-KETONES	
with <i>N</i> nucleophiles		base-induced rearrangement of sulfonyl oximes	18-12
phenols + amines	13-06	ketones + HCHO + amines	16-19
or ammonia		Mannich reaction	16-19
radical addition to C=N compounds	16-56		

AMINO-NITRILES		aromatic compounds + alkyl	11-11
from cyanohydrins	10-32	halides	
HCN or cyanide +	16-53	aromatic compounds +	14-19
C=N compounds		carboxylic acids	
		aromatic compounds + ketones	11-12
AMINO-THIOETHERS		aryl halides + active methylene	13-14
alkenes + sulfonamides	15-55	compounds	
alkenes + sulfonium salts +	15-55	aryl halides + alkenes	13-10
amines		aryl halides + alkenes	15-21
		aryl halides + alkynes	15-21
AMINO-THIOLS		aryl halides + organocuprates	10-58
episulfides + amines	10-35	aryl halides + RM (other metals)	10-59
or ammonia		aryl halides + vinylboronic acids	13-09
		aryl halides + trifluoroborates	13-09
AMMONIUM SALTS		aryldiazonium salts + alkenes	13-25
alkyl halides + amines	10-31	aryldiazonium salts + alkenes	13-26
		aryldiazonium salts + alkyl	13-25
		organometallics	
ANHYDRIDES		by decarboxylation	12-40
acyl halides + carboxylic acids	16-66	by radical cyclization	15-30
aldehydes + acyl peroxides	14-09	coupling of aromatic compounds	11-15
carboxylic acids + vinyl esters	16-67	cyclodehydration of carbonyl	11-13
dehydration of carboxylic acids	16-67	compounds	
dehydration of	16-67	Friedel–Crafts alkylation	11-11
dicarboxylic acids		from alkylborates	10-59
		from boranes	10-59
ANHYDRIDES,		hydrogen exchange	11-01
ORGANIC–INORGANIC		rearrangement of <i>N</i> -alkyl	11-32
anhydrides + mineral acids	16-68	aryl amines	
		replacement of aryl nitro	13-29
ARENES			
α -halo ketones +	10-58	AROMATIC COMPOUNDS	
organocuprates		aromatic compounds + carbenes	15-64
alkyl halides + ArM (Li, Na, K)	10-57	aromatization of six-membered	19-01
alkyl halides + aryl-M	13-17	rings	
(M = a metal)		cleavage of arenes	11-33
alkyl halides + arylboronic acids	13-09	cleavage of aryl alkyl ethers	11-37
alkyl halides + organocuprates	10-58	cyclization of ene-diyne	18-27
alkyl halides + aryl	10-57	cyclotrimerization of alkynes	15-65
organometallics		deamination of aromatic	19-69
aromatic compounds + active	13-17	compounds	
H compounds		decarbonylation of aryl	11-34
aromatic compounds +	14-17	aldehydes	
acylperoxides		decarboxylation of aryl	11-35
aromatic compounds + alcohols	11-11	carboxylic acids	
aromatic compounds + alkenes	11-11		

dehalogenation of aryl halides	11-39	AZIRINES	
dehydrogenation of	19-01	alkynes + amino-nitrenes	15-54
cyclic alkanes			
desulfonylation of aryl	11-38	AZO COMPOUNDS	
sulfonic acids		aryl amines + nitroso	13-24
from aromatic compounds	18-28	compounds	
protonation of aryl	11-41	aryl diazonium salts +	11-04
organometallics		aromatic compounds	
pyrolysis of bicyclic dienones	17-28	from aryldiazonium salts	13-28
reduction aryl diazonium salts	19-69	oxidation of hydrazines	19-05
reduction of phenols	19-55	rearrangement of aryl triazenes	11-30
reduction of quinones	19-01	rearrangement of azoxy	18-43
		compounds	
AZIDES		reduction of azoxy compounds	19-68
aldehydes + metal azides	16-78	reduction of nitro compounds	19-80
alkenes + hydrazoic acid	15-10		
alkenes + metal azides	15-53	AZOXY COMPOUNDS	
amides + sulfonyl azides	12-11	from alkyl halides	10-45
from acyl halides	10-43	nitroso compounds +	12-51
from alkyl halides	10-43	hydroxylamines	
hydrazines + HONO or	12-49	reduction of nitro compounds	19-79
nitrosyl compounds			
AZIDO-ALCOHOLS		BIARYLS	
from epoxides	10-43	aromatic compounds +	14-18
		aryl halides (<i>hv</i>)	
AZIDO-AMINES		aromatic compounds +	11-16
from aziridines	10-38	aryl organometallics	
		aromatic compounds +	14-17
AZIRIDINES		aryl organometallics	
alkenes + alkyl azides	15-54	aromatic compounds +	11-16
alkenes + halogen +	15-54	arylboronates	
haloamines		aryl halides + alkyl or aryl	13-09
C=N compounds + sulfur ylids	16-47	organometallics	
extrusion of nitrogen	17-34	aryl halides + aryl	13-11
from triazolines		organometallics	
form halo-amines	10-31	aryl halides + arylboronic acids	13-09
from allene amides	15-09	aryl halides + arylboronic acids	13-12
from azido-alcohols	10-43	aryl halides + trifluoroborates	13-12
from epoxides	10-36	aryldiazonium salts + aromatic	13-27
from halo-azides	15-45	compounds	
from hydroxy-amines	10-32	arylsulfonic acid + arylboronic	13-05
from imines	16-32	acids	
from triazolines	15-58	by benzidine rearrangement	18-36
imines + diazo compounds	16-32	by Suzuki–Miyaura coupling	13-12
		coupling 2 aryldiazonium salts	13-28

coupling aryl halides	13-11	CARBOXYLIC ACIDS	
coupling of aromatic compounds	11-15	acyl halides + diazo compounds	18-08
coupling of aryl sulfonates	13-12	acyl peroxides + alkyl organometallics	12-26
Ullmann coupling	13-11	alkylation of carboxylic acids	10-70
BISAMIDES		aromatic compounds + carbon dioxide	11-20
aldehydes + amides	16-18	aromatic compounds + carbon monoxide	11-20
BISULFITES		aromatic compounds + phosgene	11-19
metal bisulfite + carbonyl compounds	16-12	aryl nitro compounds + cyanide	13-30
BORANES		Barbier–Wieland procedure	19-10
alkenes + borane or alkyl boranes	15-16	boranes + ether-acids	18-24
boranes		by decarboxylation	12-40
thermal migration of boron in boranes	18-11	by Michael addition	15-24
BORATES (TRIFLUORO)		carboxylation of alkenes	15-35
boranes + KHF_2	12-28	cleavage of diketones	12-43
BORATES		cleavage of keto-esters	12-43
alcohols + boranes	12-28	cleavage of ketones	12-45
borates		cleavage of methyl ketones	12-44
oxidation of boranes	12-27	deacyloxylation	19-59
BORONIC ACIDS		esters + metal halides	10-51
alkyl borates + alkyl organometallics	12-28	from lactones	10-51
BUNTE SALTS		from RM + arenes	10-57
from alkyl halides	10-28	hydrolysis of acyl halides	16-57
CARBAMATES		hydrolysis of amides	16-60
alkyl halides + amines	10-17	hydrolysis of anhydrides	16-58
amines + alkyl halides + CO_2	12-53	hydrolysis of carboxylic esters	16-59
amines + CO_2	12-53	hydrolysis of diazo ketones	18-08
from aziridines	12-53	hydrolysis of nitriles	16-04
haloformates + amines	16-72	hydrolysis of ortho esters	10-6
isocyanates + alcohols	16-08	hydrolysis of trihalide	10-03
CARBONATES		ketones + peroxy acids	18-19
alcohols + phosphine	16-10	organometallics + CO_2	16-30
		oxidation of aldehydes	19-23
		oxidation of aromatic rings	19-10
		oxidation of aromatic side chains	19-11
		oxidation of organoiron compounds	10-77
		oxidation of primary alcohols	19-22
		oxidative cleavage of alkenes	19-10
		oxidative cleavage of alkynes	19-10
		ozonolysis of alkenes	19-09

phosphoranes + CO ₂	16-44	from alkyl halo sulfites	10-17
pyrolysis of esters	17-04	from coupling of activated esters	10-61
rearrangement of ketones via the haloform reaction	18-19 12-44	from onium salts	10-17
		from tosyl amides	10-17
CARBOXYLIC ESTERS		hydrolysis of ortho esters	10-06
acyl halides + alcohols	16-61	insertion of diazo esters	12-21
acyl halides + ethers	16-61	ketones + acyl halides	16-07
alcohols + CO + alkenes	15-36	ketones + peroxides	18-19
alcohols + ketenes	15-05	oxidation of methylene in ethers	19-17
alcohols + organoiron compounds	10-77	oxidation of primary alcohols	19-22
alcoholysis of acyl oxazolidinones	16-65	oxidation of vinyl ethers	19-25
alcoholysis of amides	16-65	oxidative decarboxylation	19-12
alcoholysis of nitriles	16-09	oxygenation of organometallics	12-29
alcoholysis of trihalides	10-03	rearrangement of halo ketones	18-07
aldehydes + acyl halides	16-07	ring contraction of diazo ketones	18-08
alkenes + acyl peroxides	14-09	transesterification	16-64
alkenes + carboxylic acids	15-06	via Mitsunobu coupling	10-17
alkenes + carboxylic esters	15-33		
alkyl halides + carboxylate anions	10-17	CONJUGATED ALDEHYDES	
alkylation of oxazolidines	10-72	by aldol condensation	16-34
allylic carbonates + malonates	10-60		
allylic esters + malonates	10-60	CONJUGATED AMIDES	
anhydrides + alcohols	16-62	isocyanates + vinyl-M (metal)	15-22
aryl halides + alcohols + CO	13-15		
aryl halides + alcohols + metal carbonyls	13-15	CONJUGATED CARBOXYLIC ACIDS	
Baeyer–Villiger rearrangement	18-19	aldehydes + anhydrides	16-39
by Favorskii rearrangement	18-07	by the Knoevenagel reaction	16-38
by Michael addition	15-24	CO ₂ + vinyl-M (metal)	15-22
by the Tishchenko reaction	19-82		
carbonylation of alkyl halides and alcohols	10-77	CONJUGATED DIACIDS	
carboxylic acids + diazo compounds	10-19	by the Knoevenagel reaction	16-38
cleavage of keto-esters	12-43		
condensation of aldehydes	19-82	CONJUGATED DIKETONES	
condensation of ketones	19-84	by the Knoevenagel reaction	16-38
esterification of carboxylic acids	16-63		
esters + ethers	10-18	CONJUGATED ESTERS	
ethers + anhydrides	10-18	by the Knoevenagel reaction	16-38
from acyl peroxides	14-09	Claisen condensation	16-36
		CONJUGATED KETO-ESTERS	
		by the Knoevenagel reaction	16-38

CONJUGATED KETONES

alkenes + acyl halides	12-16
by aldol condensation	16-34
by the Pauson–Khand reaction	15-36
carbonylation of vinyl-M (M = metal)	12-33
coupling of dienones	15-20
oxidation of methylene	19-17

CONJUGATED NITRILES

by the Knoevenagel reaction	16-38
-----------------------------	-------

COUMARINS

from phenols	11-11
--------------	-------

CUMULENES

elimination of propargylic halides	17-22
---------------------------------------	-------

CYANAMIDES

amines + cyanogen halides	10-54
---------------------------	-------

CYANATES, ARYL

phenols + cyanogen halides	10-08
----------------------------	-------

CYANIDES, ACYL

acyl halides + metal cyanides	16-88
-------------------------------	-------

CYANO IMINES

nitroso compounds + nitriles	16-42
------------------------------	-------

CYANOAMINES

see amino-nitriles

CYANOHYDRINS

aldehydes or ketones + HCN	16-52
aldehydes or ketones + R ₃ SiCN	16-52

CYCLOBUTANES

by [2+2]-cycloaddition	15-63
extrusion of SO ₂	17-36

CYCLOBUTENES

ring closure of dienes	18-27
------------------------	-------

CYCLOPROPANES

alkenes + carbenes	15-64
alkenes + diazo esters	15-58
by the Simmons–Smith reaction	15-64
conjugated carbonyls + sulfur ylids	16-49
extrusion of nitrogen from pyrazolines	17-34
extrusion off CO from cyclobutanones	17-35
from pyrazoles	17-34
from pyrazolines	15-58
rearrangement of dienes	18-39

DIACETATES

oxidation of dicarboxylic acids	19-13
---------------------------------	-------

DIALDEHYDES

alkylation reactions	10-67
----------------------	-------

DIAMINES

aziridines + amines or ammonia	10-38
diamination of alkenes	15-53
from azido-amines	10-38
reductive coupling of imines	19-76

DIAZO COMPOUNDS

acyl halides + diazomethane	16-89
base-induced elimination of <i>N</i> -nitroso compounds	17-33
oxidation of hydrazones	19-06

DIAZONIUM COMPOUNDS

active methylene compounds + sulfonyl azides	12-10
aldehydes + sulfonyl azides	12-10
aromatic compounds + HONO	11-05
aryl amines + HONO	13-19

DICARBOXYLIC ACIDS

by Michael addition	15-24
from aryl isothiocyanates	11-21
oxidative cleavage of cyclic alkenes	19-10
oxidative cleavage of ketones	19-08

DIENES

addition of alkenes to dienes	15-20
addition of alkynes to alkynes	15-20
allylic halides + metals	10-56
by the Diels–Alder reaction	15-60
by the Wittig reaction	16-44
cleavage of cyclobutanes	15-63
Cope rearrangement	18-32
coupling of alkynes and allenes	15-20
coupling vinyl boranes	14-26
cycloaddition of dienes	15-66
dehydration of alkyne-alcohols	17-01
dienes + acyl metal compounds	12-16
from aromatic compounds	18-27
hydrogenation of aromatic compounds	15-13
hydrogenation of diyenes	15-11
metathesis of alkenes	18-37
other cycloaddition reactions	15-66
pyrolysis of bicyclic alkene-ketones	17-28
pyrolysis of sulfoxides	17-20
rearrangement of dienes	18-32
ring closure of trienes	18-27
ring opening of cyclic alkenes	18-27
sigmatropic carbon migration	18-30
sigmatropic H migration	18-29
Stille coupling	12-15
vinyl halides + metals	10-56
vinyl halides + RM (other metals)	10-59
vinyl-X + vinyl-M	12-15

DIESTERS

active methylene compounds + alkyl halides	10-67
alkenes + acyloxy salts	15-56
alkylation reactions	10-67
dimerization of acetals	10-64

DIHALIDES (GEMINAL)

alkenes + halogenating agents	16-23
ketones + halogenating agents	16-23

DIHALIDES

alkynes + HX	15-02
dihalogenation of alkenes	15-39
from alkyl halides + trihalides	10-57

DIKETONES

acyl halides + active H compounds	16-84
acylation of enamines	10-69
alkylation reactions	10-67
by Michael addition	15-24
conjugate addition of acyl halides	15-32
conjugate addition of RM with metal carbonyls	15-32
conjugated ketones + metals	10-56
coupling acyl halides	16-83
dimerization of silyl enol ethers	19-33
esters + ketones	16-86
from dithioketals	16-86
hydrolysis of furans	10-6
ketones + diazo-ketones	12-21
oxidation of alkynes	19-26
oxidation of methylene	19-17
oxidative cleavage of cyclic alkenes	19-10

DINITRILES

alkylation reactions	10-67
----------------------	-------

DIOLS

alkenes + formaldehyde	16-53
alkenes + halogens + metal carboxylates	15-48
by the Tollens reaction	16-43
dihydroxylation of alkenes	15-48
from halo-esters	15-48
hydride shifts of epoxides	18-41
hydrolysis of epoxides	10-7
hydrolysis of epoxides	15-48
ketones + formaldehyde	16-43
oxidation of aromatic compounds	15-49
pinacol coupling	19-76

reduction of lactones	19-38	EPISULFIDES : see thiiranes	
reductive coupling of aldehydes or ketones	19-76	EPOXIDES	
		aldehydes or ketones + halo-organometallics	16-24
DISULFIDES		diazonium compounds + aldehydes or ketones	16-46
aryl halides + sulfides	13-04	epoxidation of alkenes	15-50
from alkyl halides	10-27	from halohydrins	10-9
oxidation of thiols	19-34	sulfur ylids + aldehydes or ketones	16-46
reduction of sulfonyl halides	19-71		
DITHIOACETALS		EPOXY-ALCOHOLS	
aldehydes + thiols	16-11	allylic alcohols + peroxides	15-50
from dihalides	10-26		
DITHIOCARBAMATES		EPOXY-AMIDES	
amines + carbon disulfide	16-22	epoxidation of conjugated esters	15-50
DITHIOKETALS		EPOXY-CARBOXYLIC ACIDS	
alkylation of dithioketals	10-71	epoxidation of conjugated acids	15-50
from dithioketals	10-13		
from dithiols	10-13	EPOXY-ESTERS	
ketones + CS ₂	16-42	diazo esters + aldehydes	15-64
ketones + thiols	16-11	epoxidation of conjugated esters	15-50
vinyl sulfides + thiols	15-07	halo esters + aldehydes or ketones	16-40
DITHIOLS		EPOXY-KETONES	
alkenes + sulfur reagents	15-51	epoxidation of conjugated ketones	15-50
DIYNES		EPOXY-NITRILES	
metal coupling of alkynes	14-16	epoxidation of conjugated nitriles	15-50
ENAMIDES		ESTER-AMIDES	
amines + vinyl halides	12-32	isonitriles + carboxylic acids + aldehydes	16-98
ENAMINES		isonitriles + carboxylic acids + ketones	16-98
alkylation of enamines	10-71	ESTER-SULFIDES	
alkynes + amines	15-08	by the Pummerer rearrangement	19-83
from hydroxy-amines	16-13	rearrangement of sulfoxides	19-83
ENOL ETHERS : see vinyl ethers			
ENOLS			
and keto-enol tautomerism	12-03		

ESTERS : see carboxylic esters**ESTERS, INORGANIC**

from alcohols	10-22
from sulfonyl halides	10-22
phosphites + alkyl halides	16-44

ETHER-AMINES

rearrangement of halo-amines	18-18
------------------------------	-------

ETHER-ESTERS

conjugated esters + alcohols	15-05
------------------------------	-------

ETHER-KETONES

acetals + vinyl ethers	10-64
oxidation of methylene	19-15

ETHERS

acyl peroxides + alkyl organometallics	12-26
alcohols + diazo compounds	10-11
alcohols + onium salts	10-15
alcohols + sulfonate esters	10-10
aldehydes + alcohols	16-07
alkenes + alcohols	15-05
alkenes-alkoxymercuration	15-05
alkylation of ethers	10-71
aryl halides + alkoxides	13-03
cleavage of oxonium salts	10-49
dehydration of alcohols	10-12
from alcohols (Williamson ether synthesis)	10-08
from alcohols + phenols	10-12
from alkyl halides (Williamson ether synthesis)	10-08
from carboxylic esters	10-10
from dihalides	10-10
from halo-ethers	10-08
from halohydrins	10-09
from lactones and organometallics	16-30
from trichloroimidates	10-10
ketones + alcohols	16-07
Michael addition with <i>O</i> nucleophiles	15-31

oxidative cyclization of alcohols	14-06
phenols + diazo compounds	10-11
rearrangement of aryl sulfones	13-33
reduction of esters	19-62
reduction of lactones	19-62
reductive cleavage of acetals or ketals	19-56
transesterification	10-13

ETHERS, SILYL

Brook rearrangement	18-44
cleavage of ethers	10-49
rearrangement of hydroxy-silanes	18-44

FORMAMIDES

amines + trihalides	10-40
---------------------	-------

GLYCIDIC ESTERS : see epoxy-esters**HALIDES, ACYL**

acyl halides + HF	16-80
aldehydes + halogens	14-04
anhydrides + HF	16-80
carboxyl acids + halogenating agents	16-79
oxidation of primary alcohols	19-22

HALIDES, ALKYL

alcohols + HX	10-48
alcohols + inorganic acid halides	10-48
aldehydes + halo-boranes	16-23
alkenes + alkyl halides	15-46
alkenes + halogens	14-01
alkenes + HX	15-02
carboxylate salts + halogens	14-30
cleavage of amines	10-53
cleavage of ethers	10-49
cleavage of oxonium salts	10-49
from amines	10-53
from esters	10-51
from inorganic esters	10-47
from silyl ethers	10-48

from sulfonate esters	10-47	from alkynes	12-31
halide exchange with alkyl halides	10-46	halide exchange with vinyl halides	10-46
halo-decarboxylation of acids	16-71	halogens + vinyl boranes	12-31
halogens + alkyl organometallics	12-31	halogens + vinyl-M (M = a metal)	12-31
halogens + boranes	12-31		
halomethylation of arenes	11-14	HALO-ALCOHOLS	
		cleavage of cyclic ethers	10-49
HALIDES, ALLYLIC		from aldehydes or ketones	16-24
alkanes + halo-succinimides	14-03		
alkenes + halogens	14-03	HALO-ALDEHYDES	
		aldehydes + halogen	12-04
HALIDES, ARYL		aldehydes + halogenating agent	12-04
aromatic compounds + halo-succinimides	11-10	alkenes + formamides	15-47
aromatic compounds + halogen	11-10		
aryl ammonium salts + halide ion	11-32	HALO-ALKYNES	
aryl halides + metal halides	13-07	from alkynes	12-31
aryldiazonium salts + metal halides	14-20		
aryldiazonium salts + metal iodides	13-22	HALO-AMIDES	
from aryl amines	14-20	amides + hypohalites	12-53
from phenols	13-22	from aziridines	10-50
heating aryldiazonium tetrafluoroborates	13-23		
phenols + phosphonium halides	13-07	HALO-AMINES	
rearrangement of <i>N</i> -halo amides	11-31	alkenes + <i>N</i> -halo-amines	15-43
sulfonyl halides + transition-metal halides	11-38	amines + hypohalites	12-52
HALIDES, SULFONYL		HALO-AZIDES	
alkanes + SO ₂ + halogens	14-10	alkenes + X-N ₃	15-45
aromatic compounds + sulfonyl halides	11-08		
aryldiazonium salts + SO ₂	14-22	HALO-CARBOXYLIC ACIDS	
sulfonic acids + halogenating	16-103	carboxylic acid + halogen	12-05
		carboxylic acid + halogenating agents	12-05
HALIDES, VINYL		from amino acids	10-52
base-induced elimination of halides	17-13		
elimination of dihalides	17-22	HALO-ESTERS	
		from epoxides	10-50
		HALO-ETHERS	
		from alkene-alcohols	15-51
		HALO-KETONES	
		alkenes + acyl halides	15-47

from diazoketones	10-52	dinitriles + ammonia or amines	16-21
ketone + halogen	12-04	rearrangement of	18-31
ketone + halogenating agents	12-04	acyl aziridines	
		thermal rearrangement	18-14
HALO-LACTAMS		of azides	
halolactamization	15-41	furans—from diketones	16-05
		indoles:Fischer indole	18-34
HALO-LACTONES		synthesis	
halolactonization	15-41	oxetanes—alkenes + aldehydes	16-95
		or ketones	
HALO-NITRO COMPOUNDS		oxetanes—alkenes + ketones	15-63
alkenes + NOX	15-44	pyrans—from diketones	16-05
		pyrazoles—hydrazines +	16-14
HALO-NITROSO COMPOUNDS		di-ketones	
alkenes + NOX	15-44	pyrazolines—alkenes +	15-58
		dialkylamines	
HALO-SILANES		pyrazolines—hydrazines +	16-14
from silanes	10-16	keto-esters	
silanes + halogens	14-02	pyridine derivatives—by the	15-61
		heteroatom Diels–Alder	
HALO-SULFONES		reaction	
sulfones + halogenation agents	12-06	pyrazolidines—alkenes +	15-58
		azomethine imines	
HALO-SULFOXIDES		pyrrolidines—cleavage	15-58
sulfoxides + halogenating	12-06	of aziridines	
agents		pyrrolines—rearrangement	18-31
		of cyclopropyl imines	
HALOHYDRINS		quinolines (dihydro)—	11-13
alkenes + alcohols + halogens	15-40	cyclodehydration of imines	
alkenes + hypohalous acids	15-40	quinolines (dihydro)—from	11-13
from epoxides	10-50	amines	
		quinolines (tetrahydro)—	
HETEROCYCLES		cyclodehydration of amides	11-13
acylation of amines	16-77	quinolines (tetrahydro)—from	11-13
aromatization of	19-01	amines	
six-membered rings		HYDRATES	
by the heteroatom	15-61	from ketones or aldehydes	16-01
Diels–Alder reaction			
by the Paterno–Büchi reaction	15-63	HYDRAZIDES	
by [3+2]-cycloaddition	15-58	carboxylic esters + hydrazine	16-75
condensation of aldehydes	16-92		
cyclization of amino-ketones	16-13	HYDRAZINES	
or aldehydes		reduction of azo compounds	19-51
cyclization of halo-amines	18-40	reduction of diazo compounds	19-51
dehydrogenation reactions	19-02		

HYDRAZONES

- active methylene compounds + aryldiazonium 12-07
 exchange of hydrazine + hydrazones 16-14
 from azo compounds 12-07
 from ketones 12-07
 hydrazines + aldehydes or ketones 16-14

HYDROXAMIC ACIDS

- carboxylic esters + hydroxylamine 16-75

HYDROXY-ALDEHYDES

- by aldol condensation 16-34
 dihydrooxazines + epoxides 10-72
 imines + ketones 16-34
 Mukaiyama aldol 16-35
 oxidation of epoxides 19-20
 silyl enol ethers + aldehydes 16-35

HYDROXY-AMIDES

- aldehydes + amides 16-18
 alkenes + amides 15-52
 alkenes + sulfonyl amines 15-52

HYDROXY-AMINES

- alkenes + amines 15-52
 epoxides + amines or ammonia 10-35
 from isonitriles 10-40
 from nitro-alcohols 10-35
 oxetanes + amines or ammonia 10-37
 reductive coupling of C=N with C=O 19-76
 water induced rearrangement of halo-amines 18-10

HYDROXY-AZIRIDINES

- from amino-epoxides 10-36

HYDROXY-CARBOXYLIC ACIDS

- by the Cannizzaro reaction 19-81
 rearrangement of 1,2-diketones 18-06

HYDROXY-ESTERS

- Baylis–Hillman reaction 16-27
 Claisen condensation 16-36
 epoxides + carboxylate anions 10-14
 from epoxides and RCOOH 10-18
 Reformatsky reaction 16-28
 transesterification of lactones 16-64

HYDROXY-ETHERS

- epoxides + alcohols 10-14

HYDROXY-KETONES

- acyloin condensation 19-78
 aldehydes + cyanide 16-55
 aldehydes and cyanide 15-32
 Baylis–Hillman reaction 16-27
 by aldol condensation 16-34
 by rearrangement of hydroxy ketones 18-04
 by the Tollens reaction 16-43
 coupling of carboxylic esters 19-78
 hydrolysis of diazo ketones 10-05
 ketones + formaldehyde 16-43
 Mukaiyama aldol 16-35
 oxidation epoxides 19-20
 oxidation of methylene 19-15
 photolysis of epoxy-ketones 10-07
 rearrangement of silyloxy epoxides 18-02
 reduction of epoxy ketones 19-35
 silyl enol ethers + ketones 16-35

HYDROXY-NITRILES:

see cyanohydrins

HYDROXY-NITRO COMPOUNDS

- from epoxides 10-35
 the Henry reaction 16-37

HYDROXY-PHOSPHONATES

- phosphonate esters + carbonyl compounds 16-44

HYDROXY-PHOSPHORAMIDES

phosphoramides + carbonyl compounds 16-44

HYDROXY-THIOCYANATES

epoxides + thiocyanate 10-14

HYDROXY-THIOETHERS

Claisen condensation 16-36

alkenes + disulfides + carboxylic acids 15-51

from epoxides 10-26

HYDROXYLAMINES

addition of organometallics to oximes 16-31

oxidation of amines 19-27

rearrangement of amine oxides 18-21

reduction of nitro compounds 19-46

IMIDES

acylation of amines 16-77

alkyl halides + imides 10-41

anhydrides + ammonia or amines 16-73

from alcohols 10-41

from aryl isothiocyanates 11-21

isocyanates + phosphine oxides 16-93

IMIDINES

dinitriles + ammonia or amines 16-21

IMINES

active methylene compound + nitroso compound 12-08

addition of organometallics to nitriles 16-33

aldehydes + amines or ammonia 16-13

alkynes + amines 15-08

ketones + amines or ammonia 16-13

oxidation of primary amines 19-21

rearrangement of cyclopropyl 18-31

reductive alkylation 16-17

of aldehydes or ketones 18-14

thermal rearrangement of alkyl azides 18-14

IMINO ESTERS

halo-imines + aroxides 18-42

ISOCYANATES

amides + hypohalites 18-13

amines + CO 12-53

base induced rearrangement of hydroxamic acids 18-15

carboxylic acids + HN_3 18-16

Curtius rearrangement 18-14

from acyl halides 10-44

from alkyl halides 10-44

from nitrile oxides 18-44

Hofmann rearrangement 18-13

phosgene + amines 16-72

the Schmidt reaction 18-16

thermal rearrangement of acyl azides 18-14

ISONITRILES (ISOCYANIDES)

alkyl halides + cyanide 10-75

amines + trihalides 10-40

dehydration of formamides 17-31

from oxetanes 10-40

ISOTHIOCYANATES

from acyl halides 10-44

from alkyl halides 10-44

ISOTHIOURONIUM SALTS

from alkyl halides 10-25

KETALS

ketones + alcohols 16-05

reductive cleavage of ortho esters 19-56

KETENES

base-induced elimination 17-14

of acyl halides

dehydration of carboxylic acids	17-01	KETO-SULFONIC ACIDS	
elimination of halo acyl halides	17-23	ketone + sulfur trioxide	12-14
KETENIMINES		KETONES	
by the Wittig reaction	16-44	1,3-elimination of diols	17-25
dehydration of amides	17-01	1,3-elimination of halo-amines	17-25
KETO-ALDEHYDES		1,3-elimination of halohydrins	17-25
ketals + formamides	12-16	acyl halides + organometallic compounds	16-81
KETO-ALKYNES		addition of organometallics to nitriles	16-33
elimination of epoxy-hydrazones	17-27	aldehydes + boranes	12-18
KETO-AMIDES		aldehydes + transition-metal complexes	12-18
alkenes + acyloxy salts + nitriles	15-56	alkenes + aldehydes	15-34
amino acids + anhydrides	12-42	alkenes + alkenes + CO	15-36
KETO-CARBOXYLIC ACIDS		alkenes + ketones	15-33
active H compounds + CO ₂ or CS ₂	16-42	alkyl halides + organoiron compounds	10-76
carboxylic acids + esters	16-87	alkylation of enamines	10-69
KETO-ESTERS		alkylation of hydrazones	10-68
acyl halides + active H compounds	16-84	alkylation of ketones	10-68
aldehydes + diazoketones	12-18	alkylation reactions	10-67
alkylation reactions	10-67	amines + HONO	12-50
Claisen condensation	16-85	and keto-enol tautomerism	12-03
halo-esters + esters	16-28	aromatic compounds + acyl halides	11-17
halo-esters + nitriles	16-28	aromatic compounds + aldehydes	14-19
KETO-NITRILES		aromatic compounds + anhydrides	11-17
acyl halides + active H compounds	16-84	aromatic compounds + carboxylic acids	11-17
by the Thorpe reaction	16-50	aromatic compounds + nitriles	11-24
condensation of nitriles	16-50	arylation of ketones	13-14
esters + nitriles	16-86	by decarboxylation	12-40
KETO-SULFONES		by Michael addition	15-24
acyl halides + active H compounds	16-84	by Pinacol rearrangement	18-02
		by rearrangement of ketones	18-04
		by the Wacker process	19-25
		carbonyl transposition	12-14
		carbonylation of metal alkyls	13-15
		carboxylic acids + organolithium reagents	16-29
		cleavage of alkoxides	12-41

cleavage of diketones	12-43	ozonolysis of alkenes	19-09
conjugate addition	15-25	pyrolysis of hydroxy-alkenes	17-32
of organometallics		radical addition to	15-28
conjugated addition of boranes	15-27	conjugated ketones	
cyanoboranes + anhydrides	18-23	rearrangement of diols	18-02
decarboxylative alkylation	14-31	rearrangement of epoxides	18-02
decarboxylative coupling	16-90	rearrangement of peroxides	18-20
of 2 acids		reductive coupling	19-77
dialdo ketones + boranes	10-73	of keto-esters	
Friedel–Crafts acylation	11-17	ring expansion	18-03
from cyanohydrins	10-68	of amino-alcohols	
from dihydrooxazines	10-72	ring expansion of halohydrins	18-03
from dithioketals	16-11	silyl enol ethers +	10-68
from keto-sulfoxides	10-67	alkyl halides	
halo ketones + boranes	10-73	transesterification	16-64
homologation of ketones	18-09	of vinyl esters	
hydration of alkynes	15-04	transition metal carbonyls +	12-33
hydration of allenes	15-04	RM (M = metal)	
hydrolysis	16-02	Weinreb amides +	16-82
of C=N compounds		organometallic compounds	
hydrolysis of dithioketals	10-71		
hydrolysis of <i>gem</i> -dihalides	10-2	LACTAMS	
hydrolysis of imines	16-33	alkyl halides from amides	10-41
hydrolysis of ketals	10-6	and Michael addition	15-31
hydrolysis of nitro	16-03	by Beckmann rearrangement	18-17
compounds		cyclic ketones + HN ₃	18-16
hydrolysis of vinyl ethers	10-6	cyclic ketones + silyl azides	18-16
hydrolysis of vinyl halides	10-1	from amino carboxylic acids	16-74
imines + RM	10-69	from halo-amides	10-41
insertion of diazo ketones	12-21	lactams + amines	16-76
ketenes + alkenes	15-63	lactones + ammonia	16-75
keto esters + alkyl halides	10-67	or amines	
ketones + diazomethane	18-09	<i>N</i> -arylation	10-41
oxidation alkenes	19-25	<i>N</i> -vinylation	10-41
oxidation of alcohols	19-03	oxidation of methylene	19-17
oxidation of dicarboxylic	19-13	in amines	
acids		rearrangement of oximes	18-17
oxidation of methylene	19-17	reduction of imides	19-64
oxidation of nitro compounds	19-21	Schmidt reaction	18-16
oxidation of primary amines	19-21		
oxidation of vinyl boranes	18-26	LACTAMS, β	
oxidative cleavage of alkenes	19-10	diazoketones + C=N	16-96
oxidative cleavage of diols	19-07	compounds	
oxidative cleavage	19-10	enamines + ketenimines	16-96
of enamines		ketones + C=N compounds	16-96

rearrangement of hydroxy-halo-amines	18-18	metal cyanides + aryl organometallics	13-08
		metal cyanides + alkyl organometallics	12-34
LACTONES		rearrangement of isonitriles	18-21
alkenes + carboxylic acids and Michael addition	15-57	reduction of nitro compounds	19-49
Bayer–Villiger rearrangement	18-19		
condensation of dialdehydes	19-81	NITRITES : see inorganic esters	
cyclization of allene	15-06		
carboxylic acids		NITRO COMPOUNDS	
from halo-carboxylic acids	10-17	alkanes + alkyl nitrates	12-09
from hydroxy-carboxylic acids	16-63	alkanes + nitronium salts	12-09
oxidation of methylene in ethers	19-17	alkenes + nitric acid	12-09
photolysis of halo-amides	18-40	aryldiazonium salts + metal nitrites	14-21
rearrangement of cyclic ketones	18-19	by Michael addition	15-24
rearrangement of lactones	18-44	conjugated carboxylic acids + HNO ₃	14-13
reduction of anhydrides	19-63	from alcohols	10-42
		from alkyl halides	10-42
LACTONES, β		nitration of aromatic rings	11-02
ketones + aldehydes or ketones	16-95	oxidation of amines	19-28
		oxidation of isocyanates	19-28
NITRATES : see inorganic esters		oxidation of oximes	19-28
		rearrangement of nitro-amines	11-28
NITRILES			
aldehydes + hydroxylamines	16-16	NITRO-ALCOHOLS:	
alkenes + HCN	15-38	see hydroxy-nitro compounds	
alkyl halides + cyanide	10-75		
aromatic compounds + trihalo nitriles	11-25	NITRONES	
aryl halides + metal cyanides	13-08	from oximes	10-24
aryl triflates + metal cyanides	11-25	oxidation of oximes	19-06
base-induced elimination of hydrazones	17-29		
by decarboxylation	12-40	NITROSO COMPOUNDS	
by Michael addition	15-24	Barton rearrangement	18-40
carboxylic acids + cyanogen halides	16-94	nitrosation of aromatic rings	11-03
cyanation α to active hydrogen compounds	12-19	oxidation of amines	19-27
cyanation α to nitrogen	12-19	rearrangement of nitroso-amines	11-29
cyanoborates + metal cyanide	12-34		
dehydration of amides	17-30	NITROSO-AMINES	
dehydration of oximes	17-29	amines + HONO	12-50
dehydrogenation of amines	19-05		
		ORGANOMETALLICS	
		alkanes + metals	12-23

alkanes + alkyl organometallics	12-22	PEROXIDES	
alkenes + metal hydrides	15-17	acid halides + alkyl hydroperoxides	10-21
alkyl halides + metals	12-38	alkenes + oxygen	14-07
alkyl halides + alkyl organometallics	12-39	alkenes + oxygen	15-62
alkynes + metal hydrides	15-17	alkenes + peroxides	14-08
aryl halides + metals	11-40	alkyl halides + hydroperoxide anion	10-21
aryl halides + R-M (M = a metal)	11-40	alkyl halides + hydroperoxide anion	10-21
formation of enolate anions	12-23	acid halides + hydrogen peroxide	10-21
isonitriles + organolithium reagents	16-99	anhydrides + hydrogen peroxide	10-21
metal halides + RM (M = metals)	12-36	dienes + oxygen	15-62
metalation of aromatic compounds	13-17	oxidation of carboxylic acids	19-24
metals + RM (M = metals)	12-35	oxygen + alkyl organometallics	12-25
thioethers + organometallics	14-28	oxygen + organoboranes	12-25
transmetallation of RM + R'M' (M = metals)	12-37	photooxidation of dienes	15-62
ORTHO ESTERS		PHENOLS	
by transesterification	10-13	aromatic compounds + acyl peroxides	11-26
carboxylic acids + alcohols	16-05	aromatic compounds + peroxides	14-05
from trihalides	10-8	aryl halides + hydroxide	13-01
OSAZONES		aryl sulfonic acids + hydroxide	13-02
hydrazines + hydroxy aldehydes or ketones	16-14	aryldiazonium salts + water	13-20
OXIMES		by Wallach rearrangement	18-43
alcohols + NOCl	18-40	Claisen rearrangement	18-33
aldehydes or ketones + hydroxylamine	16-15	Fries rearrangement	11-27
alkenes + NOX	15-44	oxidation of aromatic compounds	11-26
aryldiazonium salts + oximes	14-23	oxidation of aryl borates	13-01
Barton rearrangement	18-40	oxidation of arylboronic acids	13-01
carbonyl compounds + nitrous acid	12-08	rearrangement of allyl aryl ethers	18-33
O-alkylation of oximes	10-24	rearrangement of aryl esters	11-27
reduction of nitro compounds	19-49	rearrangement of aryl hydroxylamines	13-32
OXONIUM SALTS		rearrangement of dienones	18-05
alkyl halides + ethers	10-20	PHOSPHINES	
		alkenes + phosphines	15-08
		phosphines + aryl halides	13-05
		reduction of phosphine oxides	19-68

PHOSPHONATE ESTERS :		SULFONAMIDES	
see inorganic esters		addition of arylboronates to C=N	16-31
PHOSPHONIUM SALTS		dealkylation of sulfonamides	19-73
alkyl halides + amines	10-31	reduction of acyl sulfonamides	19-64
phosphines + ammonium salts	10-31	reduction of sulfonyl azides	19-50
		sulfonyl halides + ammonia or amines	16-102
PHOSPHORANES		SULFONATE ESTERS	
and the Wittig reaction	16-43	alkenes + sulfonic acids	15-06
QUINONES		sulfonamides + alcohols	16-101
and dyotropic rearrangement	18-44	sulfonyl halides + alcohols	16-101
oxidation of aromatic compounds	19-04	SULFONES	
oxidation of aromatic compounds	19-19	alkenes + sulfonyl halides	15-42
oxidation of phenols	19-04	alkyl halides + sulfinic acid salts	10-29
SELENIDES		alkyl halides + sulfonyl halides	10-29
aryl halides + selenide	13-04	alkylation of sulfones	10-67
from alkyl halides	10-26	alkylation of sulfones and Michael addition	10-71 15-31
SELENOCARBONATES		aromatic compounds + sulfonic acids	11-09
from isocyanates	16-08	aromatic compounds + sulfonyl halides	11-09
SELENOETHER-ALDEHYDES		aryl halides + sulfonate	13-04
aldehyde + diselenide	12-14	oxidation of sulfoxides	19-31
SELENOETHER-KETONES		oxidation of thioethers	19-31
ketone + diselenide	12-14	sulfones + organometallics	10-61
SELENOXIDES		sulfonyl halides + arylboronic acids	16-105
alkylation of selenoxides	10-71	sulfonyl halides + organometallics	16-105
SILANES		SULFONIC ACIDS	
addition of silanes to alkene	15-19	aryl halides + sulfonates	13-04
and dyotropic rearrangement	18-44	hydrolysis of sulfonyl halides	16-100
aryl halides + silanes	13-16	oxidation of sulfur compounds	19-30
from metalated aryls	10-55	oxidation of thiols	19-30
		rearrangement of aryl sulfones	13-33
SULFINIC ACIDS		reduction of sulfonyl halides	16-104
RM (M = a metal) + sulfonating agents	12-30	sulfonation of aromatic compounds	11-07

sulfonation of aromatic compounds	11-36	THIOESTERS	
sulfonation of methylene	19-16	acyl halides + thiols	16-69
SULFONIUM SALTS		esters + sulfur reagents	16-11
alkyl halides + thioethers	10-26	THIOETHER-ALDEHYDES	
SULFONYL IMINES		aldehyde + disulfides	12-14
sulfonamides + aldehydes	16-18	THIOETHER-KETONES	
SULFOXIDES		enol ethers + disulfides	12-14
alkylation of sulfoxides	10-67	ketone + disulfides	12-14
aromatic compounds + sulfonyl halides	11-09	THIOETHERS (SULFIDES)	
oxidation of thioethers	19-31	alkenes + thiols	15-07
TELLURIDES		aromatic compounds + sulfones	11-23
from alkyl halides	10-26	aryl halides + alkyl sulfides	13-04
THIRANES (EPISULFIDES)		aryldiazonium salts + sulfide	13-21
diazo compounds + sulfur	16-48	aryldiazonium salts + thiols	13-21
alkenes + sulfur reagents	15-50	from alcohols	10-26
from epoxides	10-26	from alkyl halides	10-26
from halo-ketones	10-9	from ammonium salts	10-26
thioketones + sulfur ylids	16-48	from dihalides	10-26
THIOAMIDES		Michael addition	15-31
amides + sulfur reagents	16-11	with <i>S</i> nucleophiles	
amides + sulfur reagents	16-70	rearrangement of sulfonium salts	18-21
from nitriles	16-04	reduction of sulfones	19-72
THIOCARBAMATES		reduction of sulfoxides	19-72
from isocyanates	16-08	sulfur + alkyl organometallics	12-30
hydrolysis of thiocyanates	16-04	thiols + arylboronic acids	13-04
THIOCARBOXYLIC ACIDS		thiophenols + aromatic compounds	13-04
acyl halides + sulfur reagents	16-69	THIOKETONES	
THIOCYANATES		ketones + sulfur reagents	16-11
aryl halides + thiocyanate	13-04	THIOLACTAMS	
aryldiazonium salts + thiocyanate	13-21	lactam + sulfur reagents	16-11
from alkyl halides	10-30	lactones + sulfur reagents	16-11
from amines	10-30	THIOLS	
		alkyl halides + hydrogen sulfide or HS ⁻	10-25
		aryl halides + sulfide	13-04

aryldiazonium salts + hydrogen sulfide	13-21	VINYL ETHERS (including silyl enol ethers)	
from alcohols	10-25		
hydrolysis of Bunte salts	10-28	alcohol + enol ester	10-13
reduction of disulfides	19-75	alcohol + enol ether	10-13
reduction of sulfonyl halides	19-71	by the Wittig reaction	16-44
sulfur + alkyl organometallics	12-30	cleavage of acetals or ketones	17-02
THIOUREAS		form esters	16-45
amines + CS ₂	16-22	from aldehydes	12-17
isothiocyanates + amines	16-20	from ketones	12-17
		from phenols	10-8
TRIAZOLES		peroxides + vinyl-M (M = a metal)	12-26
alkenes + alkyl halides	15-58	Petasis alkenylation	16-45
		Tebbe alkenylation	16-45
TRIAZOLINES		VINYL PHOSPHINES	
alkenes + alkyl azides	15-58	alkynes + phosphines	15-08
TRIENES		VINYL SILANES	
aromatic compounds + carbenes	15-64	addition of silanes to alkynes	15-19
cycloaddition of dienes	15-66		
ring opening of cyclic dienes	18-27	VINYL SULFIDES	
		alkynes + thiols	15-07
TRIHALIDES		ketones + thiols	16-11
acyl halides + halogenating agents	16-23	VINYL SULFONES	
cleavage of methyl ketones	12-44	alkynes + sulfonyl halides	15-42
		from sulfinic acid salts	10-29
TRIOXANES		XANTHATES	
from aldehydes	16-92	carbon disulfide + alcohols	16-10
UREAS			
amines + CO ₂	16-22		
isocyanates + amines	16-20		

AUTHOR INDEX

Entries in this index refer to chapter number (**boldface**) and reference number.
